Another point of interest is that effective couples can be made in this way. For example, in the preparation of diphenyl methane,<sup>1</sup> instead of adding aluminium mercury couple, an effective nascent couple is obtained by adding a little aluminium and mercuric chloride. The yield was quite as good as that obtained by the usual method, with the further advantage that the couple prepared in situ is always effective, and is more certain in its action than the ordinary couple.

Observations indicate that oxychlorides may in some cases be better than normal chlorides, for the use of the former involves the possibility of a thermite as well as a displacement reaction.

At present the application of the above facts for widening the scope of reactions is being investigated.

### Degree of Weathering of Soils

IN the modern study of soils, there is an urgent need for methods of analysis which will express quantitatively the fundamental properties and genetic relationships of the material examined. We are venturing to suggest a provisional method whereby an approximate estimate may be obtained of the extent to which chemical weathering has proceeded in a given soil.

Assuming that the clay fraction separated in mechanical analysis represents that portion of the soil which has resulted from processes of chemical weathering—the so-called weathering complex—and that the remainder of the soil consists of unweathered minerals, such as feldspars, and unweatherable minerals, such as quartz, the proportion of the total alumina of the soil present in the clay fraction should give a rough measure of the degree to which chemical weathering has proceeded. Since the principal clay-forming minerals are complex aluminosilicates, a soil which has reached the end-point of weathering

will contain no alumina in its non-clay fraction. On the other hand, a soil in the early stages of chemical weathering will contain considerable amounts of alumina as unweathered aluminosilicates in the non-clay fraction. We therefore propose, as a measure of the degree of weathering, the amount of alumina in the clay fraction, calculated as a percentage of the total alumina of the soil. For example, if a certain soil contains 20.5 per cent of alumina, of which 16.4 per cent is in the clay fraction, the degree of weathering is 80 per cent. A parallel estimate may be obtained from the percentage of the total ferric oxide of the soil present in the clay fraction, but in many cases, particularly in tropical soils, there are considerable proportions of secondary ferric oxide in the non-clay fraction. Indeed, with lateritic soils, the partition of alumina is equally untrustworthy as a measure of the degree of weathering.

We have divided the soils examined by this method into two categories, namely, (1) soils derived by primary weathering from crystalline rocks, and (2) soils derived from materials such as alluvium and marine sediments which have already undergone one or more cycles of weathering. In Category 1, we may distinguish (a) soils such as those in Britain, in which chemical weathering has only proceeded to a moderate extent, and (b) soils of the humid tropics, in which chemical weathering is far advanced.

We have examined five soils in Category 1 (a), six soils in Category 1 (b), and seven soils in Category 2. Our results are shown in the following table, which gives the average degree of weathering calculated from the alumina and from the ferric oxide data respectively.

|                | Degree of Weathering calculated from |                                |
|----------------|--------------------------------------|--------------------------------|
|                | Al <sub>2</sub> O <sub>3</sub>       | Fe <sub>2</sub> O <sub>3</sub> |
| Category 1 (a) | 33.0 (18.6-40.3)                     | 32.1 (15.5-43.1)               |
| Category 1 (b) | 76.5 (58.4-89.7)                     | 66.1 (58.6-94.3)               |
| Category 2     | 82.9 (70.5-93.4)                     | 64.5 (48.5-84.3)               |

It will be seen that the figures obtained are in good agreement with expectation, for the tropical soils and the soils of secondary origin show much higher degrees of weathering than the relatively immature soils derived by primary weathering under British conditions. The degrees of weathering calculated from the ferric oxide data are in the same order as those calculated from the alumina, but are rather lower, partly on account of the presence of ferric oxide of secondary origin in the non-clay fraction, and partly on account of the presence, in some cases, of unweatherable minerals of the magnetite group.

Though only approximate in character, the proposed method may serve as a simple procedure for obtaining an estimate of the relative maturity of soils, and may, therefore, aid in the sub-classification of the major soil groups. It may also find an application in the study of regolithic materials.

#### Function of the Spiracles of Insects

In carrying out investigations on the respiration of insects, with particular reference to the action of the spiracles and the factors which control their activity, one is struck by the divergence of the results recorded by previous workers. It appears that they have tended to look upon the spiracles only in connexion with gaseous exchange (oxygen and carbon dioxide). Respiration, however, also entails a water metabolism.

Feeling that the tracheal system may have an importance hitherto overlooked in the water balance of the insect, both in respiration and temperature control, efforts have been made to assess the various avenues of water exchange, using larvae and pupae of *Galera mellonella* (Lepidoptera). Preliminary experiments show that a large part (a first approximation gives 50 per cent of total) of the water exchange occurs via the trachea and spiracles.<sup>1</sup>

The results obtained may help to explain the different observations upon spiracular behaviour at increased temperature. Thus, while at one time the spiracle may be opening to deal with an increased gas exchange at increased temperature, it may later begin to close to avoid injurious desiccation.

The problem is complicated by the increase in the rate of gaseous diffusion at high temperatures, which tends to overcome the need of spiracular opening. The experiments performed, however, give generally concordant results and uphold the idea put forward very well. The technique is simple and allows of concurrent observations on the localisation of carbon dioxide exchange, and it is hoped to shortly publish a full account of the results.

#### Preparation and Mounting of Deliquescent Substances

CERTAIN deliquescent crystals were required for structural investigations. The following method of preparation and mounting was found satisfactory.

A tube 1.5 cm. in diameter was drawn down at one end to a short tube 0.75 cm. across, and at the other to a capillary. The apparatus was warmed and a stream of dry carbon dioxide was passed through from the capillary end. When the apparatus was dry, the substance to be sublimed was introduced, the gas flow stopped, and the end of the narrow tube sealed. The capillary was then attached to a 'Hyvac' pump, the apparatus evacuated and sealed off.

The tube was heated in an air oven until good crystals were obtained. When cool, a scratch was made at the base of the narrow tube, and a piece of thin rubber tubing was slipped over it until it gripped the wide tube. The rubber tubing was connected to the supply of dry carbon dioxide. The tube was then broken at the scratch, thus filling the apparatus with dry gas. The broken glass was pushed down the rubber tubing until a sufficient length was free to be clipped. The end was then cut off, and a piece of lithium glass tube, drawn down to a capillary at one end, was inserted, carbon dioxide being passed meanwhile. The capillary was then sealed and the clip removed. A piece of stout wire was pushed through the rubber and used to dislodge the crystals, one at a time. After dropping into the capillary tube, they were sealed off separately. The crystals are liable to move unless the tube tapers.

Slight changes in technique enabled crystals grown from solution or fusion to be mounted in the same way.

When optical measurements were to be made, the crystal was dropped into a small spherical bulb blown on the end of a short tube. A fine glass rod dipped into tap fat was passed through the hole in the rubber, and the crystal, suitably oriented, was picked up on the end of this. The rod was then melted into the side of the tube, and the whole sealed off.

## Research Items

**The Campas Indians, East Peru**—Some notes on the culture of the Campas Indians of eastern Peru are given by Prof Morris G Caldwell and Mr John Calhoun in the *Scientific Monthly* for March. An area covering several thousand square miles of jungle and mountainous land and intersected by several tributaries of the upper Amazon is characterised by a common culture sufficiently uniform to justify the name of 'the Campas Culture-area'. It extends from the Pachitea River south to the Mantaro, and from the Ucanah westward to a line from Jauja to Huanaco. The Indians possess a well-developed culture, though it appears to be retarded. They use bamboo arrows three feet long, tipped with a sharpened palmwood head sixteen inches long. Four small prongs encircle the point to catch in the flesh. Blunt hardwood heads are used for killing small birds. Fish arrows have three prongs. The bow is of palmwood five feet long. A hunting axe of dull porous stone hafted on a two-foot wooden handle is used. The principal means of transportation is by canoe—a dugout about thirty-five feet long and five feet wide. It is made from palmwood by the use of axe and fire. Pottery jars are made from the yellow river clay; they are used for carrying water, fruit berries, etc. Garments are made from cotton which grows wild, and are often decorated with feathers, bunches of bone, seeds, nuts, toes of small animals, and bones of small birds and monkeys. The dress is a slip-over garment without sleeves and a poncho. They chew coca leaf and have an intoxicating liquor made from yucca root chewed by the old women.

**Egyptian Magic**—An Egyptian bilingual papyrus, long in the British Museum but unknown to scholars, has been translated and edited by H I Bell, A D Nock, and Herbert Thompson (*Proc Brit Acad*, vol 17). It gives a number of short magical formulæ current in Egypt, presumably at the date of writing, which is placed at somewhere towards the end of the third century A D. The procedure is usually to invoke a god or some higher power and compel him to assist the invoker in procuring what he wishes. In the present collection the Demotic text includes an invocation to Thoth for aid, a method to discover a thief, spells for reputation, and an amatory spell. The Greek texts are mainly concerned with the last named. In a spell to obtain an answer to a dream, a laurel leaf is placed under the head when the invoker goes to sleep. On it are written seven invocations, that is, seven strange forms of the names of Horus and Thoth, to which *kh* has been added, possibly representing some peculiarity in pronunciation of the divine name. In "the way of finding a thief", the head of a drowned man is used, a stalk of flax grown from the ground under which it has been buried for the purpose, being used to tie the magical knot which binds the thief. In a charm to win a woman's love, a figure of Osiris in wax, wound in ram's wool, is buried with the bone of a lizard under her threshold, while a spell is chanted to Isis at the rising of the moon. The influence of the lizard is seen again in a charm in the Greek text, of which the object appears to be to secure the woman's love by ensuring her separation from her husband. Numerous examples of the use of the lizard in medicine and erotic magic are collected in the editorial notes.

**Flocking Habits of Birds**—The use of bird-ringing (or banding, as it is called in America) in conjunction with bird traps has brought to light some interesting features regarding the grouping of birds during the

winter or non-breeding season. On the campus at Stanford University, California, flocks of golden-crowned and white-crowned sparrows (*Zonotrichia coronata* and *Leucophrys pugetensis*) arrive on autumn migration or stay over the winter until the return in April and May. To supplement the ringing method, which entails the handling of birds for identification, some feathers of the birds were distinctively stained so that the individuals could be recognised in the field. The results, recorded by John B Price (*Condor*, 1931, p 238), show a constant return of the same bird to the same area and even the same trap. The author concludes that both species spend the winter in definite flocks, each with its own range of 15-20 acres. Between the flocks there is very little interchange of individual birds, and the memory of the territory seems to persist from year to year, for in most cases an individual bird was found to return to its original flock territory after migration.

**Classification of the Gulf-Weeds**—On British coasts' the most conspicuous of the brown seaweeds are members of the group Fucales, represented by a few genera, each with one or only few species, the commonest being *Fucus* spp. In warmer seas, the group is also prolific, but represented by other genera, of which one of the more important is *Sargassum*. Unlike *Fucus*, *Sargassum* is represented by a large number—probably more than three hundred—of species, and a wide field is still open to systematists to bring the classification of this genus into a satisfactory condition. Problems are presented not only by the large number of species, but also by variations in form due to environment and to the fact that some of the species are dioecious, with morphological differences between plants of the two sexes. Dr Setchell of California has given an account (*Hong Kong Naturalist*, vol 2, No 4, 1931) of the existing schemes of classification and the main features of the five subgenera, based on the system of J C Agardh (1848-1889). He adds also a tentative artificial key for the identification of species occurring in the Hong Kong region, where the genus is well represented. This should prove of great assistance to any who have opportunities of studying the genus further.

**Maize Hybrids with *Tripsacum***—Induced parthenogenesis is a possible method of obtaining homozygous strains instead of prolonged inbreeding. Mangelsdorf and Reeves (*J Her*, vol 22, No 11) attempted to produce such seeds in maize by pollinating it with a related grass, *Tripsacum dactylodes*. This species extends from the Atlantic to Texas, the Texas form used having narrower leaves and  $2n=36$  chromosomes, while the Connecticut form has  $2n=72$ . Crossing with the Texas type was obtained by shortening the maize silks or stigmas to about two inches. By double pollination it was found that hybrid seeds develop better adjacent to normal seeds. No parthenogenetic embryos were obtained, but the hybrid seeds usually showed 38 chromosomes. In maize  $n=10$ , so with double fertilisation an endosperm containing  $10+10+18$  chromosomes should be found. The embryos of these seeds usually had 28 chromosomes. When pollen from the tetraploid *Tripsacum* was used, seedlings were obtained with 46 chromosomes in their root tips, as expected. Most of the seeds in these crosses were abortive and shrivelled, but could be germinated on agar. From some 185,000 silks exposed to pollination, only 84 seeds matured. Certain maize varieties crossed more

readily than others, and curiously enough the tetraploid *Tripsacum* was more successful than the diploid as pollinator. The hybrids more nearly resemble the male parent, especially when the tetraploid form is used. Some plants from this cross which matured are sterile in pollen and seeds. Meiosis shows 18 bivalents, presumably the *Tripsacum* chromosomes pairing with each other, and 10 lagging maize chromosomes. Numerous small nuclei are formed, resulting in aborted pollen. The reciprocal cross, *Tripsacum* × maize, has never succeeded. These results differ in some respects from earlier work of Collins and Kempton.

**Magnetic Distribution in China and Tibet**—In *Veröffentlichungen d. Preuss. Meteorolog. Inst.*, No 379 (Abh. Bd 9, No 7), Berlin, 1931, O. Venske gives a reduction and discussion of the terrestrial magnetic observations made by W. Filchner on his expedition through China and Tibet in 1926–28. Prior to this journey, very little was known about the magnetic distribution in Tibet. Filchner measured the declination, dip, and horizontal force at about 150 stations, about 50 km apart, using a magnetic theodolite, the dip being measured with the aid of soft iron induction bars. The stations lay on two routes, each lying roughly in the east-west direction, the northern one was from Tashkent (41° N, 69° E) by Tihua (44° N, 88° E) and on to Lussar (36° N, 102° E), and the southern one from Lussar to Leh (34° N, 78° E) over the Tangle Pass, 15,000 ft above sea-level. Despite many difficulties and privations, due to ill-health and Tibetan hostility, Filchner's measurements, according to Venske, are of satisfactory accuracy. The declination nowhere differed much from 0°, confirming that the agonic line runs east-west in Tibet, local disturbances are small and suggest (in agreement with gravity data) that the non-magnetic surface rocks reach down to great depths.

**Spitsbergen Geology**—D. Sokolov and W. Bodylevsky (*Skrifter om Svalbard og Ishavet*, 35, pp. 151, pls. 14, 1931) describe the Jurassic and Lower Cretaceous faunas of the west coast of Spitsbergen and discuss their stratigraphical relationships. The horizons which have been recognised from palaeontological evidence range from Upper Callovian to Lower Aptian. Lower Callovian and Albian may also possibly be present in Spitsbergen. The Lower Aptian does not appear to have been previously recognised in the Arctic region. Typical Oxfordian is not present. The abundance of *Aucella*, of which about thirty species are described in this memoir, gives a characteristic aspect to the Upper Jurassic and Lower Cretaceous faunas and recalls that of Petschora-land. Continental conditions are indicated by the occurrence of *Ginkgo* and other plants in beds above the undoubted Valanginian and below the *Crocera* beds of the Lower Aptian.

**Atmospheric Ozone**—The main conclusion reached by D. Chalonge in his paper (*J. Phys.*, January) on the vertical distribution of ozone in the air, is that little is known about this, and that the present methods of investigation based on ultra-violet spectrophotometry are unsatisfactory. In particular, he shows that it is misleading to refer to an absorbing layer at 50 km, if this is taken to mean that the region where absorption occurs is restricted, or even that the centre of gravity of the ozone is defined by it. Ozone is, on the contrary, present in considerable quantity so low as 20 km, and, probably with a concentration increasing with height, up to 80 km, which is not much below the Heaviside layer. What appears to be most urgent is some entirely new

experimental method, if this can be devised, and, until this is forthcoming, ambiguity is likely to attach to the results obtained with current methods, including the one which makes use of ozone absorption in the yellow, which has recently been described by O. R. Wulf (*Smithsonian Misc. Coll.*, vol. 85, No. 9).

**Optical Glasses**—As the result of an examination of the properties of a large number of optical glasses as given in a manufacturer's catalogue—that of the Parsons' Optical Glass Company—Mr. T. Smith, of the Optics Department of the National Physical Laboratory, has come to the conclusion that a knowledge of the refractive indices of a glass for light of three wave-lengths is sufficient to enable the index for any other wave-length within the visible spectrum to be calculated. The refractive index for any wave-length can be expressed in the form  $a + bw^n$  where  $a$ ,  $b$ , and  $n$  are constants for each glass and  $w$  is the wave number, that is, the reciprocal of the wave-length. From this it follows that between the indices and wave numbers for three lines we have  $(\mu_1 - \mu_3)/(\mu_2 - \mu_3) = (w_1^n - w_3^n)/(w_2^n - w_3^n)$ , and if  $n$  is found so that the equation is satisfied for three lines for which the  $\mu$ 's are observed the  $\mu$  of any other line of known  $w$  may be calculated. It is therefore more convenient to define the reciprocal dispersion or constringence  $\nu$  as  $(\mu_F - 1)/(\mu_F - \mu_C)$  where  $F$  and  $C$  are the blue and red hydrogen lines, and in comparing glasses it is more useful to the computer of optical systems if  $\log \nu$  instead of  $\nu$  is plotted against  $\mu$ , and Mr. Smith hopes glass makers will publish diagrams of this kind on an agreed uniform scale in their catalogues. He considers that at present a larger variety of glasses is produced than is necessary for optical purposes. His conclusions were well received at a meeting of the Optical Society in February, 1931, and his paper and the discussion on it appear in part 3 of vol. 32 of the *Transactions* of the Society.

**Crystal Structure of Benzene**—It is somewhat surprising that although benzene is one of the simplest of organic compounds, yet its crystal structure has never been at all fully worked out. It is true that the dimensions of the unit cell have been determined consistently in two different investigations, and that the space group and the number of molecules to the cell are known, but there are various technical difficulties which make it difficult to proceed further. Some account of these, and of the way in which they have been partially overcome, has been published by E. G. Cox (*Proc. Roy. Soc.*, March). One of the major difficulties is the high vapour pressure of benzene, which is five times that of ice at 0° C, and makes it impossible to keep the solid in the open for long. To overcome this, the crystal was enclosed in a gelatin capsule, this was reasonably transparent to X-rays, and sufficiently impervious to benzene vapour when lightly coated with shellac for the crystal to be kept for several days. It was, however, still impracticable to work with an ionisation spectrometer, and hence the rotating crystal method, with a special cooled camera, had to be employed. Even so, it was not considered worth while to make other than eye estimates of intensity. The main result which emerges is that the experimental results are strongly in favour of a flat-ring molecule, a puckered ring would exaggerate some of the discrepancies observed, and would not agree with the absence of cleavage of the crystals and their considerable hardness. Beyond this, little more can be said than that the ring structure is loosely knit, the average distance from centre to centre of carbon atoms in neighbouring molecules is

about 3.8 Å, compared with 3.5 Å, which is the distance most usually found to occur in organic substances

**Reactivity of Metals with Water**—We have received from Mr. Binayendra Nath Sen, of 57 Patu-atola Lane, Calcutta, a communication in which he advances a rule that only those metals react with water at the ordinary temperature in which the distance of closest approach of the atoms is not smaller than 3.00 Å. The list includes lithium, sodium, potassium, calcium, bismuth, magnesium, cerium, and lead. Mr. Sen states that other metals are not acted upon by water at the ordinary temperature, and in them the distance of closest approach is less than 3.00 Å, with one or two exceptions.

**Oxidation of Phosphorus**—A number of new observations on the oxidation of phosphorus vapour at low pressure, which bring out the fact that this can occur in more than one way, have been described by H. W. Melville and E. B. Ludlam (*Proc. Roy. Soc., March*). They are concerned with the manner in which the reaction takes place in the presence of tungsten and platinum when the pressure is too low for an explosion, but in order to avoid the difficulties which arise in applying the usual methods for measuring low pressures in this instance, the explosion limit was made use of for this purpose by determining how much additional oxygen was required to pass to the critical value for explosion to occur. When platinum was put in the reaction chamber, the rate of reaction could be measured conveniently with it at 200° C, no glow could be seen during the reaction, and it

probably occurred at the platinum surface. With a tungsten filament, on the contrary, it was necessary to go to 500° C, and the reaction was accompanied by a green glow, from this, and from other evidence, it was concluded that the change started at the metal surface, but was propagated through the gas, and finally ended on the walls of the tube. Gold, silver, and molybdenum, although not studied in detail, appeared to behave similarly to tungsten.

**Pressure on Retaining Walls**—A paper was read before the Institution of Civil Engineers on Feb. 23 by Prof. C. F. Jenkin on "The Pressure on Retaining Walls." Researches on this subject were begun by the author in the Engineering Laboratories at Oxford in 1926, and during the last two years have been continued at the Building Research Station. An account of the work up to last year was given by Prof. Jenkin to the Royal Society, but the present paper describes the latest type of experimental apparatus and gives the results of tests on the pressure exerted by sand on walls of many types. The tests include measurements of the forces on the wall (in magnitude, direction, and position) and also the determination of the planes of rupture and the nature of the motion of the sand down the back of the wall. Approximate formulæ have been developed and their application is summarised in practical working rules. The errors in many of the old forms of wedge theory are pointed out, the reaction of the wall on the sand is discussed, and the author expresses the hope that others may be saved from the pitfalls into which he himself has fallen.

### Astronomical Topics

**New Comet**—Two telegrams and circular No. 361 from the I. A. U. Bureau, Copenhagen, announce the discovery of a comet of the ninth magnitude by Mr. H. E. Houghton (presumably at Pretoria) on April 1. It was observed at the Cape observatory as follows: April—2<sup>d</sup> 18<sup>h</sup> 0<sup>m</sup> U. T., R. A. 13<sup>h</sup> 39<sup>m</sup> 16<sup>s</sup>, S. Decl. 75° 50', daily motion, -6<sup>m</sup> 0<sup>s</sup>, N. 1° 26'. No orbit is to hand, but the rapid northward motion may bring it into the view of European astronomers before very long. Actually the U. T. of the above observation was given as 6<sup>h</sup>, but as there was daylight at the Cape at that time, it is presumed that 18<sup>h</sup> was meant.

There is some doubt as to the letter that should be assigned to this comet. Nothing more has been heard of the object reported by Prof. van Biesbroeck on March 6, also, the status of the Delporte object of March 12 is still in doubt—it may be either a comet or a planet.

The comet Grigg-Skjellerup should now be within reach of moderate telescopes, the following ephemeris for 0<sup>h</sup> is from *B. A. A. Circular*, No. 111.

| April 15 | R. A. 6 <sup>h</sup> 23 <sup>m</sup> 6 <sup>s</sup> | N. Decl. 2° 10' |
|----------|-----------------------------------------------------|-----------------|
| " 20     | 6 33 54                                             | 4 5             |
| " 25     | 6 46 0                                              | 6 17            |
| " 30     | 6 59 42                                             | 8 52            |

The comet is likely to be large and diffused.

**Brazilian Tide Tables for 1932**—These tide tables were calculated at the Observatory of Rio de Janeiro, with the aid of a Kelvin tide-predictor, and are published by the Brazilian Ministry of Education. They give the times of every high and low water throughout the year for the fifteen principal ports of Brazil, also the height of water above the zero marks on the tide gauges at the ports. The marked differences between the heights of the tides at the different ports are of interest. The range appears to be smallest at Rio de Janeiro, where the range at the highest springs

scarcely exceeds a metre. The port of St. Luiz is at the other extreme, on April 21, which is the highest tide of the year, the range from high to low water is 5.8 metres. Some of the ports show a considerable diurnal term, by comparison between the two high waters twelve hours apart. There is much in the book that will interest students of the tides, their astronomical interest has increased since it was shown by Taylor and Jeffreys that tidal friction is probably sufficient to explain the excess of the moon's acceleration over that arising from astronomical causes.

**The Delporte Object**—The determination of an elliptical orbit for this object from the early observations presented difficulties, owing to the object being nearly in opposition to the sun. It is unlikely that the orbit is really parabolic, but the following parabola, by S. Arend of Uccle, represents the observations with fair accuracy up to the end of March, the observed declination is then 3' north of the predicted one.

$$\begin{aligned} T &= 1932, \text{ April } 4 \text{ } 0284 \text{ U. T.} \\ \omega &= 25 \text{ } 662^{\circ} \\ \Omega &= 171 \text{ } 694 \\ i &= 20 \text{ } 137 \\ q &= 1 \text{ } 16335 \end{aligned} \quad \left. \vphantom{\begin{aligned} T \\ \omega \\ \Omega \\ i \\ q \end{aligned}} \right\} 1932 \text{ } 0$$

The following recent observations made at Uccle are published in *R. I. Circ.* 584.

|                 | R. A. 1932.0                                                   | N. Decl.      |
|-----------------|----------------------------------------------------------------|---------------|
| March 23 812165 | 13 <sup>h</sup> 26 <sup>m</sup> 7 <sup>s</sup> 16 <sup>s</sup> | 20° 55' 27.8" |
| " 26 976600     | 13 53 42 37                                                    | 25 32 6.1     |
| " 28 914416     | 14 10 32 39                                                    | 28 0 28.6     |

Uccle positions of March 23, 24, and 25, previously published, were erroneous, belonging to a different object. The Delporte object was photographed at Heidelberg on March 26, the magnitude being 14. It was noted as doubtful, but is confirmed by the Uccle observation.

### The Wheat Problem

THE Twentieth Report of the Imperial Economic Committee, originally intended for presentation at the Ottawa Conference in 1931, which was eventually postponed, has been issued in the form of a survey,\* without recommendations, of the present wheat position, with an analysis of the chief causes—economic, technical, social, and political—contributing thereto, together with indications as to which are in all probability temporary and which of a more permanent character. The fact that over vast areas of land the growing of wheat, the primary foodstuff of the world, does not repay the cost of production is a problem of the first magnitude for the Empire and for the world in general, and it is evident that such a situation has been brought about by the interaction of a number of complex causes.

In the report a statistical treatment is made of the changes in price, production, acreage, yield, and international trade that have taken place since 1920, special attention being paid to the later years of the period. Figures for Russia are excluded on account of their uncertainty and the exceptional position occupied by Great Britain during the years under consideration.

Since 1921 the trends of prices of wheat and general commodities have been very similar, this suggests that the changes in wheat prices are not solely attributable to causes peculiar to wheat production or marketing. Production, although in excess of effective demand in recent years, is actually lower than that normally expected from the pre-War trend, so that the term 'over-production' is a relative one only. The re-entry of Russia into the export trade, however, has done much to intensify the disparity between supply and demand. As a result, at the end of the crop year 1930-31, curtailment in wheat production was taking place in all the principal

exporting countries except Canada and Russia. The expansion which had occurred during the previous nine years was due to an increase in area harvested, rather than to any changes in the average yield per acre, which for the world as a whole has not shown much variation. Biological and, particularly, mechanical improvements in the methods of wheat production during the post-War period have had far-reaching economic consequences, for the result has been an increased output at a lower cost of production of a commodity for which a corresponding increase in consumption was not obtained.

Comparison is made between the policies adopted by certain important exporting and importing countries, and, almost throughout Europe, State action has been taken with the view of raising internal wheat prices in the interest of local producers. The most significant and, at the same time, the most uncertain feature of the present situation, however, is Russia. The existence of a wheat-producing country and potential exporter of the magnitude of Russia, the policy of which is not directly related to the international level of wheat prices, introduces completely new economic considerations into the question and complicates the task of assessing the world's situation.

The outlook for the season 1931-32, as summarised by the International Institute of Agriculture, indicates that the total world's production, including Russia, is, on the whole, insufficient to cover the requirements of consumption, so that it will be necessary to draw upon the accumulated stocks which continue to depress the market, but, nevertheless, it is estimated that they will still remain heavy at the end of the current crop year.

The wheat problem is, however, fundamentally a general problem, and the removal of the obstacles which to-day impede the recovery of industrial life would go a long way towards bringing about an improvement in the wheat situation.

### Recent Excavations in British Honduras

THE report of the first and second Marshall Field Archaeological Expeditions to British Honduras serves to point the moral that, in archaeological investigation, it by no means follows that the outstanding site or the sensational discovery in the long run makes the most illuminating contribution to knowledge of the culture of the people under investigation.

The settlements explored by these expeditions in 1928 and 1929 were situated in a peripheral area of Maya culture, in which neither exceptional development nor an advanced standard in the arts of life could be expected, while in themselves they were not of sufficient importance to justify inclusion even in the rank of fourth class sites. Yet, being in part residential, they give a truer view of the life and customs of the people than do more imposing ceremonial centres. The material they have yielded will constitute a considerable contribution toward what is much needed, namely, the formulation of an ordered sequence of pottery types and styles within a defined cultural area, which will serve as a basis for systematic and intensive study of the cultural history of circumjacent regions in an ever-widening circle. Toward this a beginning has now been made in the investigations undertaken, or projected, by the Carnegie Institu-

tion of Washington at Uaxactun (Guatemala) and the Field Museum of Chicago in north-central Honduras.

The sites investigated by the two expeditions, of which Mr. Eric Thompson was the leader, are situated in the Cayo district of British Honduras, on the western frontier, where it borders on Guatemala. The actual site of the excavations was twenty-five miles south-east of the town of El Cayo in the neighbourhood of the Mountain Cow Water Hole. Except for a scarcity of water, the site was admirably adapted to Maya settlement, having an abundance of game and a salubrious air owing to its height. In fact, these settlements are the highest cities in the 'Old Empire' area, Hatzcap Ceel, described in this report, being probably as much as 2250 ft. above sea-level. The country being very broken, the inhabitants were practically cut off from cities to the south, such as Pusilha and Lubaantun, though only forty miles away. To the west and north-west—to Ixkun, about thirty-three miles, and Ucanal, twenty-seven miles away—the country was easily traversed. Although it is not known with certainty which tribes inhabited this area when the Spaniards came, it is probable either that they were Mopans, who are known to have occupied the country immediately to the west, or were closely allied to that people. It is suggested tentatively that in ancient times these Mountain Cow Water Hole area cities were inhabited by Chol-speaking Mayas.

\* "Archaeological Investigations in the Southern Cayo District, British Honduras." By J. Eric Thompson. Field Museum of Natural History, Publication 301. Anthropological Series, vol. 17, No. 3.

Four groups of sites within a two-mile radius of the Mountain Cow Water Hole area were excavated. Of these, two, Hatzcap Ceel and Cahal Pichik, were ceremonial centres and two, Tzimin Kax and Cahal Cumil, were residential sites.

The two ceremonial centres flourished at the close of Cycle 9 and the beginning of Cycle 10 in Maya dating. Evidence for this is afforded by two dated monuments, of which the dates correspond to A.D. 835 and A.D. 910. There is evidence also of a succession of construction periods in the superposition of buildings, though not all these must be taken to represent distinct culture phases. The pyramids were found to be in a collapsed condition. Each of the ceremonial sites possibly had a ball court between two pyramids. Most of the pyramids of the temple type yielded votive caches. The contents of these caches were generally uniform in character, seven of the ten found containing characteristic small figurines of jade, slate, or shell. Other offerings were jade and small objects, including a worked flint of eccentric form with three arms, or points, two lobster-claw-shaped and one tau-shaped. In five of the seven caches containing figurines were containers in the form of a barrel-shaped cylindrical urn. One of the offerings is a mask which is undoubtedly the finest jade object yet found in British Honduras. It is now in the British Museum. A mirror of iron pyrites was found at Hatzcap Ceel, but the remains of what was probably a second were too far corroded to permit of certain identification.

The evidence of the pottery showed that these two sites belong to the same general cultural area as Holmul, Yalloch, and Uaxactun—an area in which art, as exemplified in stone carving on altar and stela, did not fall far short of that of the larger cities of the Peten region in what is now Guatemala, but architecture and the ability to erect large carved stone monuments did not penetrate here until late in the Old Empire period. It would appear that the art of erecting large multiple vaulted buildings never reached the Mountain Cow Water Hole region.

The two residential sites, Tzimin Kax and Cahal Cumil, consist of a number of scattered plazas of small size, constructed on the tops of natural hillocks enlarged by piling around them masses of stone and rubble up to a height of three or four feet above the

natural summit. The whole was then levelled up, and pyramidal square and low oblong mounds erected at the edge of the platform thus constructed. The platforms average twenty-five metres in each direction and are orientated within three or four degrees of true north. The outside walls were made of blocks of stone roughly faced but unsquared. The fill is of large limestone boulders and a small amount of rubble, but is loose. There is evidence that the platforms were reconstructed on several occasions.

A number of burials was associated with most of the plazuelas. This would be fully in accord with what we know of Maya practice. Bishop Landa says that it was customary for the people of Yucatan to bury their dead under the house, and among the modern Maya, children are buried under the floors of the huts. It is to be noted that in a burial at Tzimin Kax a number of small crude pots were found in pairs, one being placed mouth downwards over the other. Three of these contained bones: in one the first, second, and third dactyls of a human hand, judging by its size, of a woman or adolescent, and in a second a single bone, which proved to be the second dactyl of a small adult's hand. Dr. Gann also records the finding of the terminal phalanx of "a Maya lady's little finger" from a burial near Progreso. The skeletal remains were in a bad state of preservation, but Prof. Elliot Smith reported on two skulls as showing marked antero-posterior deformation.

The two residential sites were evidently occupied for a longer period than the ceremonial centres. Reference to the classification made by Dr. Vaillant at Holmul shows that all four sites were occupied in the period Holmul V, while the earlier period of Holmul I is represented in burials at both the residential sites. At Cahal Cumil there is certain evidence which points to a still earlier period of 'pre-Holmul'. Pottery of the same type has been found at Uaxactun in conditions which point to its being earlier than Holmul I. It must be remembered that although this correspondence with Holmul is established in the Mountain Cow Water Hole area, it does not necessarily follow that in absolute dating the two are contemporary, the latter being a peripheral area. Holmul pottery may have reached it at a later date. It is clear that the sites were not occupied after the introduction of metal.

### Forecasts of Fisheries

A REPORT of the activities of the various area committees of the International Council for the Exploration of the Sea has recently been published.\* In small compass, it may be said to place before the public of the different nations represented in the Council the aims and present achievements of marine investigation. Amongst a wealth of valuable and interesting material, the report of the Northern North Sea Committee deserves special mention, as recording a notable landmark in the history of fishery research.

In the work of this Committee, most attention is being given to the herring and the haddock—the two most important commercial fishes of the northern North Sea. As a result of this concentration of effort, there is being built up, slowly but surely, a very definite knowledge of the composition of the stocks of these two species which is of immediate value for an understanding of the fluctuations in the practical fisheries. Much still remains to be accomplished,

more particularly with regard to the correlation of these fluctuations in the year classes of fish entering the marketable stocks with the successive changes in hydrographical and biological conditions in the sea.

Nevertheless, the work on the haddock has reached a stage when the yield of the North Sea haddock fisheries for eighteen months or two years ahead can be anticipated with great accuracy. Definite forecasts, made only experimentally as yet, have proved most satisfactory. For example, the general success of a forecast made in April 1929 at the scientific meeting of the International Fisheries Conference in London is cited. At that meeting it was stated that the fairly successful 1926 brood should, for most of its fourth year (1929), serve to provide catches just above normal. By the end of the autumn of that year, however, this brood should have made the greater part of its contribution to the catches. The 1927 brood had proved a failure, so catches would therefore be expected to sink below normal from late autumn 1929 to well on in 1930. But about August of the latter year there should take place a marked increase in the catches owing to the upgrowth of the highly successful 1928

\* Conseil Permanent International pour l'Exploration de la Mer. Rapports et procès-verbaux des réunions. Vol. 74. Procès-verbaux (Mars 1931). Pp. 203. (Copenhague: Andr. Fred. Høst et fils, 1931.) 7 75 kr.

brood In 1931 still greater catches should accrue The course of events in the commercial fishery agreed very closely with the above prediction

In the report now before us forecasts are made for an ensuing period as far forward as the middle of 1933 After the autumn of 1931, when most of the 1928 brood has been fished out, a sharp drop in the catches is predicted, owing to paucity of the 1929 and 1930 broods Landings will continue below normal throughout 1932 and during at least the first half of 1933 The result of the 1931 spawning is not known at present, but a good brood is hoped for in order to relieve the depression which always follows when two successive years produce numerically unsatisfactory broods

### Mobilities of Atmospheric Large Ions

A RECENT paper by R K Boylan entitled "The Mobilities of Atmospheric Large Ions"\* is of obvious importance in the subject of atmospheric electricity, which has engaged the attention of many meteorologists since Elster and Geitel's pioneer researches many years ago Of the two classes of ion present in atmospheric air, the large ions of small mobility discovered by Langevin are normally the most numerous, and there is general agreement in fixing their mobility at 0 00033 cm/sec/volt/cm These appear to be the principal nuclei of condensation for water vapour, and to be the result of small ions attaching themselves to uncharged particles of dust

It is pointed out by Boylan that whereas McClelland and P J Nolan have found ions of smaller mobility in air treated in various artificial ways, such as bubbling through alcohol or passage over flames, it is generally believed that ions larger than the Langevin ions, that is, ions of smaller mobility, are absent from untreated air Experiments conducted by Boylan on air in a well-ventilated room in Dublin gave strong reason for disbelieving this conclusion Experiments were made on the usual lines, air being drawn at measured speeds between two lengths of concentric brass tubing, between which high tension electric fields of various known strengths were maintained, the current being measured by an electrometer Since ions tend to group themselves around certain mobilities, these groups can be detected by looking for discontinuities in the curve obtained by plotting current against voltage, at such points all the ions of a given mobility are just collected on the inner electrode during the passage of the air through the tube Boylan used both the McClelland and Zeleny methods of working with this apparatus, and tried many variations of air speed

Curves derived by both methods agreed in showing clear evidence of the presence of several groups of large ions of mobilities higher and lower than that of the Langevin ions So far from indicating 'saturation', that is, complete removal of ions, at a voltage corresponding with the mobility of the Langevin ion, the ionisation measured increased by amounts varying from 28 to 200 per cent when sufficient voltage to produce saturation was applied

The difficulties of accurate measurement of the mobility of each group were very great, for the use of very high voltage or very slow speed, or some compromise between the two, is essential when dealing with such low mobilities, and each gives rise to its particular source of error or uncertainty For this reason, Boylan does not claim to give a complete or accurate catalogue of the larger ions Among the principal groups more mobile than the Langevin ions

may be mentioned those of mobility 0 0008 and 0 0006, and among the less mobile groups those of mobility 0 0009 and 0 00006 There was striking general agreement with many of the artificially produced groups observed by J J Nolan and by McClelland and P J Nolan It is considered that very few of these ions would be found in the air of country districts

### University and Educational Intelligence

APPLICATIONS for Ramsay Memorial fellowships for chemical research, one of which will be limited to candidates educated in Glasgow, will be considered by the trustees at the end of June Particulars of the fellowships can be obtained from the Secretary, Ramsay Memorial Fellowship Trust, University College, Gower Street, WC1 The application forms must be received by, at latest, May 31

THE Carnegie Trust for the Universities of Scotland has recently had under consideration the question whether, in view of the public assistance now available to the Scottish university student, the payment of class fees from funds dedicated under the Trust deed to this object should be continued In its thirtieth annual report, the Trust's executive committee declares that the system whereby education authorities assist necessitous and deserving students has not yet reached in practice such a stage of development and uniformity as would warrant the immediate withdrawal from those eligible of the payment in part of class fees by the Trust, and that the special circumstances of the times are such as to render any such new departure inexpedient for the present The amount spent by the Trust in this way in 1930-31 was £56,366 During the past four years, inquiry into the financial circumstances of each applicant's household has been made before admission to the benefits of the Trust, and it has been determined that in the case of all entrants to the university under twenty-one years of age the minimum standard of requirement for admission to these benefits shall be the obtaining of higher grade passes in three subjects in the Leaving Certificate Examination or in recognised equivalents During the year, former beneficiaries have repaid a sum of £1891 voluntarily The Trustees' scheme for the endowment of research is reported to be functioning very successfully The awards, however, are limited to £16,000 a year, which is only half of the aggregate of the grants applied for

"RADIO and Education" is the title of a short historical survey issued by the Office of Education, Washington, of the educational uses of wireless transmission in America The work of amateurs is one phase of education by radio which the United States Army and Navy have in the past done much to foster At the present time, there is a vast amount of direct instruction by broadcast lectures, one of the most important examples of which is the National Broadcasting Company's music appreciation hour directed by Walter Damrosch in connexion with the concerts of the New York Symphony Orchestra and listened to by some millions of pupils at every lecture The 'American School of the Air' gives a half-hour period of instruction daily in historical drama, Nature study, vocational guidance, and a wide range of other topics which fit into the curricula of the public schools Of the enterprises of State departments in this field, the Ohio School of the Air is the most extensive and thorough Its programmes, comprising geography, rhythmic exercise, French, and other high-school subjects, are broadcast one hour each day and are

\* *Proc Royal Irish Academy*, vol 40, Section A, No 4

listened to in twenty-nine States. There is a clash of interests between commercial and public institutional broadcasting, the demand for radio channels for commercial use having been so great that the right of the State to use this medium even for police purposes has been challenged. Practically all the commercial broadcasting stations devote much (in the aggregate about a tenth) of their time to 'educational' programmes. There are indications, however, that the advertising programmes are gradually displacing the educational, except at educational stations.

### Calendar of Geographical Exploration

#### April 19, 1827 — The Niger and Timbuktu

M Caillié, a French government official of Sierra Leone, left Kakund, on the Nunez river, midway between Sierra Leone and the Gambia. With a small caravan of Mandingoes he crossed the region through which ran the upper tributaries of the Senegal and the Niger. He was the first European to enter the town of Jenné, on the Niger, though Park had seen it on his last journey. From Jenné he sailed down the Niger to Kabara, the port of Timbuktu, and reached that city on horseback. Caillié found the city to be a collection of mud huts, among which rose several rudely built mosques. To north-east and south of it spread vast deserts, and after a fortnight's stay, Caillié and his caravan began a march across the Sahara to Morocco. In one tract the travellers marched ten days without a drop of water, men and animals suffered severely, but ultimately Caillié won his way through Tafilet and the Atlas to Fez and Tangier. Timbuktu was first reached by a European in 1826, when Major Lang paid for his pioneer entry into the mysterious city with his life.

#### April 20, 1534 — Cartier and the St. Lawrence

Jaques Cartier sailed from St. Malo, in charge of an expedition to look for a north-west passage to the Orient. He reached Newfoundland on May 10, but was delayed by ice. Then began his series of explorations of the coasts of Newfoundland, Labrador, and the islands and straits off the coasts of Canada. In 1536, on a second voyage, he sailed up the St. Lawrence estuary and reached the site of the present Montreal, of the scenery around which and of the Lachine Rapids he left a vivid description. Cartier's work in charting these coasts and discovering the region of the St. Lawrence, which was later settled by the French, was of outstanding importance.

#### April 22, 1500 — The Coast of Brazil

Pedro Alvares Cabral sighted the coast of Brazil. He had been sent out by the Portuguese Government to follow up da Gama's discovery of an 'all sea' route to India, and da Gama had himself drawn up the sailing directions. In order to avoid the calms off the Gulf of Guinea, Cabral bore so far to the west that the coast of South America was discovered. Early in the same year the Spanish navigator, Vicente Yanez Pinson, had touched the coast of Brazil, but Cabral did not know of this.

#### April 22, 1898 — Cambridge Expedition to the Torres Straits

Dr A. C. Haddon arrived at Thursday Island in charge of an expedition closely associated with the University of Cambridge. The expedition was of a unique character, for it was the first occasion on which investigations into the psychology of primitive peoples were carried out on a thoroughly scientific

basis. Dr Haddon gathered round him for this pioneer effort a brilliant group whose names are now world-famous in psychology, including the late Dr W. H. R. Rivers, Dr C. S. Myers, Prof W. McDougall, and Prof C. G. Seligman. The scientific data gathered have been published in several volumes, which have become standard sources of inspiration for all subsequent field workers in primitive psychology and in the social and physical anthropology of native peoples. The members of the expedition visited many islands in the Torres Straits, and also studied tribes in the Central and Mekeo districts of British New Guinea and in the Baram district of Sarawak. In 1888-89, Dr Haddon paid a visit to the Torres Straits, and became deeply interested in the life of the natives, the confidence which he then inspired in them paved the way for the friendly relations essential for the success of scientific work among these 'head-hunting' tribes.

#### April 22, 1908 — Stefansson in the Arctic

Vilhjalmur Stefansson set out on an expedition, during which he discovered several Eskimo tribes and obtained much information about their way of life. Stefansson began his career of exploration by archaeological research in Iceland in 1904. In 1905 he turned to arctic research, and by 1928 had spent ten winters and thirteen summers in scientific work north of the Polar Circle, always living like the Eskimo and therefore travelling light. The Canadian arctic expedition under Stefansson in 1913-18 is estimated "to have withdrawn nearly 100,000 square miles from the areas of unknown seas and lands". On this expedition the ship *Karluk*, carrying part of the group, was crushed in the ice and sank. Its crew reached Wrangel Island, where a relief ship rescued the survivors—Capt Bartlett, commander of the *Karluk*, having bravely walked to Siberia to bring help.

#### April 23, 1556 — The English on the Arctic Coast of Russia

The *Searchthrift*, commanded by Stephen Burrough, left Ratcliffe on a voyage to search for the north-east passage. Sebastian Cabot, then a very old man, came on board to wish them God-speed. Burrough met many Russian and Finnish *lodjas* (sailing boats with boards bound fast together by willows, not riveted). These fishing boats gave him much help, and were able to sail more easily and rapidly than the *Searchthrift*. Burrough, after reaching Vaygatz, returned to Kholmogory and wintered there, intending to proceed to the mouth of the Ob River next season. Instead of doing this, he turned westwards to search for Willoughby and the two vessels lost with him in the 1553 expedition. His voyage set up a new record of arctic penetration and made it clear how great were the difficulties of voyages in these very high latitudes. He brought back interesting accounts of the life and customs of the Samoyedes.

### Societies and Academies

#### LONDON

Geological Society, Feb. 24 — G. C. A. Jackson. The geology of the N'Changa district, Northern Rhodesia. The area, which forms part of the original Rhodesian Congo Border Concession, covers approximately 800 square miles, and lies immediately to the south of the Belgian Congo border. It is a wooded peneplain, underlain by four principal series of ancient metamorphosed and unfossiliferous sediments, namely, basement schists, Muva series,

Bwana M'Kubwa series, and Kundelungu series. The complex ranges from the Archaean to possibly the Lower Palaeozoic in age. Petrological descriptions were given of all the principal rock types—G. V. Douglas. General geology of a portion of Northern Rhodesia. The climatic cycle since Tertiary times, which was first desert, changed to rain-forest conditions, and is now reverting to aridity. The evidence adduced was the deep oxidation in the mines and the presence of huge dead anthills. In the eastern part of the area, pegmatite dykes with coarse and fine crystallisation occur. The coarse texture is found on the *hanging wall*, where the dykes are inclined. Where the dykes are vertical, the coarse crystallisation is found in the centre. These dykes furnish ancient plumb lines, if the dykes are now found with the coarse crystallisation on the hanging wall, it can be inferred that the country has not been flexed since the time when these dykes were consolidated. In Northern Rhodesia this phenomenon is a means of distinguishing between the older and younger granites. The trend lines of the area run from north-east and south-west in the eastern part to north-west and south-east in the section from N'Dola to some point to the west of N'Changa, in the western part the general trend is north-east and south-west, swinging into Angola.

Royal National Academy of the Lincei, Nov. 15—Gr C Moisil Generalisation of conjugate functions—M Kourensky Integration of equations to partial derivatives of the second order with one unknown and two independent variables—M Ghermanesco. *n*-Metaharmonic functions—S Finikoff The transformation *T* of congruences of straight lines—P Barreca A method for reducing to the equator and to the equinox the separate durations of evening and morning colorations of clouds—G Devoto Investigations on the dielectric constants of liquids (6) Aqueous solutions of sulphamide The experimental data obtained indicate for sulphamide a polar formula,

probably,  $\text{NH SO} \begin{smallmatrix} \text{NH}_3^+ \\ \text{O}^- \end{smallmatrix}$ , which is analogous to that proposed for carbamide in aqueous solution, namely,

$\text{NH C} \begin{smallmatrix} \text{NH}_3^+ \\ \text{O}^- \end{smallmatrix}$ —A Ferrari and C Colla Chemical

and crystallographic investigations on complex nitrites (1) The crystallographic analogy of potassium cobaltinitrite to the potassium-lead-nickel, potassium-lead-cobalt, and potassium-lead-copper triple nitrites has recently been demonstrated, the results obtained indicating that the water often found on analysing the cobaltinitrite is not combined directly with the molecule but is water of impregnation Results of measurements on a further series of complex nitrites, isomorphous with the others, are now given  $\text{K}_2\text{Ca}[\text{Ni}(\text{NO}_2)_6]$ ,  $a = 10.29 \text{ \AA}$ , calculated density 2.75,  $\text{K}_2\text{Sr}[\text{Ni}(\text{NO}_2)_6]$ , 10.49, 2.88,  $\text{K}_2\text{Ba}[\text{Ni}(\text{NO}_2)_6]$ , 10.67, 3.02,  $\text{K}_2\text{Ca}[\text{Co}(\text{NO}_2)_6]$ , 10.17, 2.86,  $\text{K}_2\text{Sr}[\text{Co}(\text{NO}_2)_6]$ , 10.23, 3.10,  $\text{K}_2\text{Ba}[\text{Co}(\text{NO}_2)_6]$ , 10.45, 3.20 Similar compounds with copper in place of cobalt or nickel give photograms with what appear to be the lines of two isomorphous monometric lattices—G Mezzadrol (1) Action of ultra-short electromagnetic waves on silkworms irradiated prior to incubation This action produces a favourable effect throughout the whole life-cycle of the worms—hatching, growth, and spinning—and results in an increased final product—(2) Action of Italian radioactive soils on the germination of seeds and on the growth of plants The influence of finely ground Italian soil of radioactivity  $4.2 \times 10^{-9}$  per gram on plants (peas, maize) grown in the laboratory in Knopp's nutrient solution is manifested in marked increase in the length of the roots and in the development of the plants Field experiments in which the radioactive soil was used as fertiliser result in stronger and greener plants and in yields exceeding by 20 per cent or more those of the controls—A Galamini The fasting and re-nutrition curves in castrated male rats

## VIENNA

Academy of Sciences, Dec 10—L Schmid and E Kotter (1) A trityl-ether of glycogen (2) The dye of the mullein blossoms, *Verbascum* The pig-

ment is a glucoside, apparently  $\alpha$ -crocetin—A Jellinek Training experiments with long-tailed monkeys, *Cercopithecus* (1) Distinguishing objects by colour, brightness and tone Coloured cardboard boxes were used and a reward of sugar They learnt to distinguish yellow from violet—(2) The monkeys learnt to distinguish a framework box containing one lump of sugar from a similar box containing two lumps of sugar, being rewarded with the sugar when they chose the one lump—E Murr (1) Experimental reduction, by heat, of the time of gestation in the ferret (*Putorius furo*) Some ferrets were kept at 20° and some at 35° Those at the lower temperature had a gestation period of about 41½ days, those at the higher temperature about 39½ days—(2) The course of bodily temperature in mammals (*Putorius furo*) during gestation In the first part of gestation the temperature is slightly higher than in the second half—H Przibram and P Suster Antenna and leg regeneration in phasmids—P M Suster Regeneration of antenna and of Johnston's organ in the rhinoceros beetle, *Oryctes nasicornis*—P M Suster Inheritance of enforced feeding on *Drosophila repleta*. Ten generations of the fly were fed on carrot, and afterwards, for five more generations, carrot was offered as an alternative and much more frequently chosen for egg-deposition—K. Trinczer The rôle of temperature and humidity in the colour-change of frogs—K Fritsch Observations on flower-visiting insects in Styria, 1911

## WASHINGTON, D C

National Academy of Sciences (*Proc*, vol 17, No 12, Dec 15)—Carl E Seashore The natural history of the vibrato A study of the vibrato has been made by (1) phonophotographic recording of music and speech, and (2) psychophysical measurements of perception of vibrato produced synthetically by instruments A definition of vibrato is offered an artistic vibrato consists of a periodic oscillation in pitch averaging a half-tone for singers and a quarter-tone for string instruments, at an average rate of 6-7 cycles a second, usually accompanied by synchronous intensity and timbre oscillations playing a secondary rôle—Walter R Miles Measures of certain human abilities throughout the life span Manual motility and reaction speed in males show a general increase up to the 'twenties', and then a gradual decline with age It is suggested that neural conservation mechanisms become more potent with increasing age—George Grant MacCurdy The use of rock crystal by palaeolithic man Seven rock crystal tools have been found by the American School of Prehistoric Research in the lower of two Mousterian levels in a rock shelter, Les Merveilles, at Castel-Merle, near Sergeac (Dordogne)—Wilder D Bancroft, Robert S Gutsell, and J E Rutzler, jr Reversible coagulation in living tissue (9)—Morphine addiction was induced in dogs and the symptoms on sudden withdrawal of morphine (which agglomerates nerve colloids) were relieved by sodium rhodanate (which peptises the nerve colloids)—W V D Hodge Further properties of Abelian integrals attached to algebraic varieties—George D Birkhoff (1) Proof of a recurrence theorem for strongly transitive systems—(2) Proof of the ergodic theorem—O Veblen and J H C. Whitehead Correction to "A set of axioms for differential geometry"—H S Vandiver Summary of results and proofs on Fermat's last theorem (6)—P A Smith Properties of group manifolds—A Wintner and F D. Murnaghan On a polar representation of non-singular square matrices—Joseph M Dalla Valle Note on the Heaviside expansion formula—Edwin B Wilson and Margaret M Hilferty The distribution of chi-square ( $\chi^2$ )—H Bateman Relations

between confluent hypergeometric functions—G A Miller Groups involving a small number of conjugates—Marcus M Rhoades Linkage values in an interchange complex in *Zea* Evidence is given of the occurrence of reciprocal translocation (segmental interchange) in a semi-sterile maize—P C Mangelsdorf Modification of Mendelian ratios in maize by mechanical separation of gametes Separating the pollen grains by sieves into tiny and normal showed that the genes for 'starchy' and 'sugary' are genetically associated with size of pollen grain, the tiny grains accomplish fertilisation only rarely in competition with normal grains—Clyde E Keeler A probable new mutation to 'white-belly' in the house mouse, *Mus musculus*

### Forthcoming Events

#### FRIDAY, APRIL 15

SOCIETY FOR EXPERIMENTAL BIOLOGY (in Department of Zoology, University Museums, Oxford), at 10 30 A.M., 2 30, and 5 30

ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee), at 2.—J H Driberg Economic Stages of Development in Africa

SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at 36 George Street, Manchester), at 7 —Annual Meeting

#### SATURDAY, APRIL 16

SOCIETY FOR EXPERIMENTAL BIOLOGY (in Department of Zoology, University Museums, Oxford), at 10 A.M. and 2 30

#### MONDAY, APRIL 18

ROYAL GEOGRAPHICAL SOCIETY, at 5.—S T A Mirrlees The Weather on a Greenland Air Route Discussion of Meteorological Results of the B A R E

ROYAL SOCIETY OF ARTS, at 8.—Prof J C Drummond Recent Researches in the Nature and Functions of Vitamins (Cantor Lectures) (1)

#### TUESDAY, APRIL 19

ROYAL SOCIETY OF MEDICINE—Special Meeting of Fellows, at 5, General Meeting of Fellows, at 5 30

GRESHAM COLLEGE (Basinghall Street, E C 2), at 6.—A R Hinks Celestial Objects of Peculiar Interest (Gresham Lectures) (Also on April 20, 21, and 22)

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6 30 —Annual Meeting

#### WEDNESDAY, APRIL 20

SOCIETY OF GLASS TECHNOLOGY (at Sheffield University) —Annual General Meeting, at 2, Ordinary Meeting, at 2 30.—R A Hacking Recent Developments in Open Hearth Furnace Design—Dr G Zotos A New Method of Melting Glasses and Silicates

TEXTILE INSTITUTE (at Manchester), at 3 —Annual General Meeting

ROYAL SOCIETY OF ARTS (Dominions and Colonies Meeting), at 4 30.—J O P Bland China and the Future of our Far Eastern Trade (Lecture)—At 8.—J G Jarvis Instalment Buying (Lecture)

ROYAL MICROSCOPICAL SOCIETY (at B.M.A. House, Tavistock Square), at 5.—Discussion on The Microscopy of the Filterable Viruses Speakers The President, J E Barnard, Prof J C G Ledingham, Dr S P Bedson, Dr C C Hurst, Prof J McIntosh, Capt S R Douglas, Dr W J Elford, Dr G M Findlay, B K Johnson, and others

#### THURSDAY, APRIL 21

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—Dr W E Sumpner The Work of Oliver Heaviside (Kelvin Lecture)

#### FRIDAY, APRIL 22

ROYAL ANTHROPOLOGICAL INSTITUTE (Human Biology Research Committee), at 5 30.—Prof J B S Haldane Present Knowledge concerning Blood Groups

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (Annual General Meeting) (at Waldorf Hotel, Aldwych), at 6 45, followed by dinner at 7 30—Sir Robert Horne Currency and Prices (Address)

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof J B S Haldane Hereditary Transmission of Acquired Characters

#### SATURDAY, APRIL 23

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin)—Prof J K Catterson-Smith Everyday Uses of Electricity (Faraday Lecture)

## Scientific Research and Patent Law

ONE of the most striking features in the advance of present-day science is the importance which borderland sciences have come to assume. In part this has resulted from the growing tendency towards intensive specialisation, and as more and more fields are demarcated the debatable lands tend to be neglected. With the advance of science there has been a parallel growth in its diversity. Chemists and other classes of scientific worker are tending more and more to subdivide themselves into special sections which often have little in common, and the 'general practitioner', whether in medicine or elsewhere, has tended to lose caste.

Specialisation has its own grave dangers of sterility of thought and a one-sided way of regarding the problems of science or of life, and it is accordingly significant that some of the most important recent advances in science have come in the borderline fields which demand the co-operation of specialists in several branches of science. Notably this is true of advances in chemotherapy and discoveries in the vitamin field, while industrial research could provide numerous examples. The contact thus engendered between different branches of science provides the necessary safeguard against sterility of thought, and this was probably what prompted Major F A Freeth's recent suggestion that the time has come when research should be organised by divisions of science and not by divisions of practice, and that, for example, an institution devoted to the study of high temperature equilibria, in which all the necessary classes of scientific workers were engaged, would produce more valuable scientific and industrial results than the study of special problems from the scientific or industrial side.

Contact between different branches of science can, however, only be full and fertile if there are no artificial barriers of thought or practice, and from this point of view it seems at least open to question whether the proposal to differentiate between medical and other classes of patents is wise. The Medical Research Council in its recent report reverts to the question of British patent law in relation to medical research, and publishes as an appendix to the report a memorandum setting forth the views which were submitted in 1929 to the Departmental Committee appointed by the President of the Board of Trade. The proposal for special treatment of medical patents was further elaborated into a draft scheme for 'dedicated patents' in a memorandum

on British Patent Law Reform prepared by a committee representing the Association of British Chemical Manufacturers and various chemical institutions

This attempt at a compromise between the interests of the manufacturer and the views of many members of the medical profession has, however, met with severe criticism. Prof F L Pyman and other representatives of the fine chemical industry have pointed out that the scheme fails to provide the protection which the manufacturer in Great Britain requires if he is to incur the heavy expenditure required for research and development in this field, thus definitely discouraging the patenting of improved processes for the manufacture of known compounds and hindering the publication of the underlying scientific work. Moreover, the differentiation between chemical products according as they are intended or not for medical purposes involves logical absurdities and creates difficulties for the manufacturer which may be intolerable, and, by stultifying the purpose of the scheme, react against the public interest.

Differentiation between medical inventions and other classes of scientific inventions can only be logically defended to-day on a very narrow interpretation of science. On any broad view, medical science is only one of the ways in which science serves humanity. The contribution of the chemist, the physicist, the engineer, the biologist, the agriculturist, and others are no less important, and upon their efforts also the success of mankind's struggle to maintain its existence often depends.

To question the desirability of affording medical patents, medical inventions, or discoveries treatment distinct from that accorded to discoveries in other branches of science is not to assert that the present patent system is ideal or satisfies the requirements of industry, science, and society. On the contrary, Mr C C Paterson suggested in a memorandum printed in the British Science Guild's Report on the Reform of the British Patent System that we have seriously to consider whether the principles of the existing patent law are suitable to the modern conditions of industry, and particularly chemical industry, when progress depends less on discontinuous invention than on the continuous application of scientific research. If this question can be answered in the affirmative, there can be no convincing or logical reason for refusing to bring medical, biological, and agricultural products within the system. If, on the other hand, as is by no means impossible, our investigation leads to the conclusion that the principles upon which the patent law is based are obsolete, we are

faced with the responsibility of developing a new and alternative system in which medical and agricultural discoveries or inventions should receive a normal and logical treatment along with other classes of scientific discovery.

In its memorandum, the Medical Research Council discriminates between scientific discovery and invention, and recognises that, in the main, medical advances now come less from inventive ingenuity than from systematic scientific research. The arguments advanced against the patenting of medical discoveries are not altogether logical, and are so similar to those advanced in other quarters against the protection of scientific discoveries, that a strong suggestion is prompted that a solution to the problem of protecting scientific property might at least include a solution of the lesser problem of protecting medical discoveries. The growing evil of 'paper' patents drawn up in terms which cover whole fields of prospective discoveries has, as we have said before in these columns, led to serious doubts as to the suitability of our present patent law system to modern industrial conditions. No drastic modification of patent law could, however, be contemplated except through international convention. International discussions on the idea of protecting the right of scientific workers to participation in the profits arising out of their discoveries may at least assist in elucidating the whole situation, and provide an opportunity for opening up international discussions on the fundamental position of patent law, if required.

Unsatisfactory as the present position in Great Britain may be, premature action is unlikely to be beneficial. The advocates of 'dedicated patents' themselves recognise the impracticability of total abolition of patents in the medical field except by international agreement. As already urged, any discrimination between one branch of science and another in patenting is logically indefensible, on ethical grounds it may be invidious. Since it can only be effective by international agreement, it might be well to determine first the suitability of the practice of patenting for industrial needs under modern conditions, the possibility of extending some form of protection to all scientific discoveries which receive industrial application, and finally, the broad lines which any new system to supersede a patent system should take. From such discussions there should emerge a considered and scientific policy which, without discriminating between different sciences, would reconcile the requirements of industry and the encouragement of scientific discovery in ways affording the maximum public advantage.

### The Study of Wireless Principles

- (1) *Wireless a Treatise on the Theory and Practice of High-Frequency Electric Signalling* By L B Turner Pp xviii+528+31 plates (Cambridge At the University Press, 1931) 25s net

- (3) *Foundations of Radio* By Rudolph L Duncan Pp ix+246 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1931) 12s 6d net

UNDER pressure of the abnormal conditions which prevailed in the world during the years 1914-18, the thermionic valve, born a few years before, successfully passed through its early life as a practical appliance in wireless communication. Its possibilities at both the transmitting and receiving ends of the link were appreciated, and it became evident that a revolution was taking place in the practice of the art. Such a change demanded new literature and textbooks, and Mr L B Turner was one of the first in the field with his "Outline of Wireless" published in 1921. This book presented in a clear and concise manner the fundamental principles of wireless communication as then practised, with an adequate description of the part played by the thermionic valve.

The volume now under review (1) represents the continuation of the author's aim to present an account of wireless theory and practice which should be readable by a competent electrical engineer who had not studied high-frequency phenomena. In extending the work to cover the progress of engineering achievement and scientific research during the intervening ten years, the book has grown from 195 to 528 pages, although it is significant of the economic conditions of our times that the price has only increased from 20s to 25s. In considering the size of the book, it may be questioned whether, for the sake of possible completeness, it is desirable to continue to include obsolescent matter dealing with plant and apparatus, the development and applications of which have given way to the valve. Chaps v and vi of the book, occupying sixty pages, deal with spark transmitters, arcs, alternators, and crystal detectors. Even the latter item of apparatus, once so popular among broadcast listeners, has receded into the background at recent radio exhibitions. In the compilation of an up-to-date textbook on a

rapidly advancing subject such as wireless communication, the time must come when it is necessary to relegate the historical development of the subject to a mere background in, say, an introductory chapter.

In the present case the introductory chapter outlines the basic properties of waves and their use for signalling purposes, and in Chap. II the author plunges straight into an analysis of the propagation of an electromagnetic disturbance. The study of this chapter by the average electrical engineer is not made easier by the use of two systems of units throughout, since most of the formulæ involved are given in parallel columns under the headings "Electrostatics", "Magnetostatics"—surely somewhat curious names for a consideration of high-frequency phenomena. Chap. III, dealing with "Propagation of Wireless Waves Round the Earth", was found to be very refreshing as a concise, if somewhat brief, summary of the state of this portion of the subject, freed from a consideration of the enormous mass of experimental data on field intensity measurements under various conditions. The fourth chapter gives the usual analysis of the behaviour of an oscillatory circuit under the influence of an impressed e.m.f. of either the damped or the undamped type. The analysis includes a consideration of the principles of the measurement of frequency and decrement, and also the behaviour of an aerial as an oscillatory circuit.

In Chap. VII the reader is introduced to the thermionic valve, and this and the succeeding four chapters, occupying 180 pages, comprise a detailed consideration of the valve and its applications as a rectifier, amplifier, and oscillator. The student is carried forward from an elementary discussion on thermionic emission and space charge effects to consideration of the action of the part played by the third and following electrodes, as exemplified in the modern triode, screen-grid valve and pentode. Attention is continually directed to the dimensions of the various quantities involved by giving typical values for modern valves and apparatus, but the main object here has been to present a detailed analysis of the features governing operation and performance. In places, such as Chap. X, it might be questioned whether the discussion has not been made unduly complicated, but the difficulties of dealing with this portion of the subject are well known and the reviewer is loth to criticise any attempt to give a generalised treatment free from the approximations which are usually made and often make the results inapplicable to any practical case.

The section on telephony devotes to the subject the fair amount of space which it deserves in view of its importance in our everyday life. A chapter on 'antennas' deals briefly with arrays and other directive systems, and refers to the use of such arrangements for direction-finding purposes, although it is doubtful if pp 459-460 would be easily understood by one not well versed in direction-finding. Discussion of the distribution of high-frequency currents in conductors is delayed until Chap xv, while a general analysis on filters follows. The last chapter discusses the atmospheric pulse as a continuous spectrum and refers to the periodogram analysis aspect of the subject. Lack of space has, apparently, prevented the author making any allusion to the large amount of experimental work conducted for several years past in the investigation of the origin and nature of atmospherics.

The photographic illustrations are concentrated in the centre of the book in the form of thirty-one plates. While the majority of these are excellent as illustrating views of apparatus and plant not normally available for inspection by the average student, it was, perhaps, scarcely worth while including Nos 3 and 16, illustrating a variable condenser and a receiving valve such as nowadays can be seen in any shop window.

Considering the size of the book, the mistakes noted are relatively few in number. It may be pointed out that at the time the book was written, the London broadcasting station was not in Oxford Street (p 6), and that the Poulsen arcs at Leafield (p 131) were replaced by a valve transmitter several years ago. The reviewer must also complain that he dislikes very much the author's habit of attaching extensive footnotes to many of the pages of text. Footnotes are permissible as references to literature or, occasionally, as afterthoughts occurring while the book is in the proof stage, but in general, they should either be embodied in the text or suppressed altogether.

These shortcomings, however, form a very small portion of the whole book, and if the author's purpose was to nurture his "Outline" into a comprehensive survey of the fundamental principles of wireless communication, he may be congratulated upon having achieved his object. The book may be recommended to all those serious students and engineers whose interest or occupation demands that they should delve somewhat more deeply into the subject than would be the case if they desired merely to increase their general knowledge of the applications of physical science. The general pro-

duction of the book, including the diagrams and mathematical symbols, is of the high quality only to be expected from such publishers as the Cambridge University Press.

In the preface to his book Mr Turner writes: "Particularly in high frequency work does a lack of prolonged practical experience make itself apparent. Proficiency with mathematical equations and circuit diagrams is indispensable, but is not sufficient to make the student effective as an engineer. He must manipulate the things whose idealised qualities are portrayed in the circuit diagrams, and often a rather long apprenticeship proves necessary." To aid the student in passing through this apprenticeship stage, Prof J. H. Morecroft's book (2) should prove invaluable, and so far as is known, this is the first available textbook directed specifically to the teaching of radio principles in the laboratory. An introduction of thirty pages surveys very briefly the field of radio measurements and gives many practical hints on the acquisition and calibration of suitable apparatus. The remainder of the book is then devoted to fifty-one experiments, each having a clearly stated object and designed to illustrate some particular phase of radio frequency phenomena and to make the experimenter familiar with the use of all types of apparatus. The statement of the object of each experiment is followed by an analysis of the quantities involved in such a manner as to give to the student a realistic view of the theoretical principles with which it is assumed he is already familiar. Instructions are given as to the best method of dealing with the results of the experiments so as to deduce as many quantities as possible. There is no doubt that this book meets a real demand in supplying a kind of laboratory manual for the radio engineering student, and the author is to be congratulated on the production of this companion volume to his already well-known "Principles of Radio Communication", the second edition of which was reviewed about three years ago\*. The student who works conscientiously through either Turner or Morecroft to learn his fundamental principles, and also performs all the experiments described in the book now under review, will indeed be well equipped to begin his career as a qualified radio engineer.

The last book (3) under review deals not with radio communication as such, but with the elements of electricity and magnetism, a knowledge of which is usually assumed by the author of any book on wireless principles. In the course of seven

\* NATURE, vol 122, p 567, 1928

chapters the author deals with the elements of electrostatics, magnetism, electromagnetic induction, resistance and Ohm's law, and the construction and use of primary cells. The eighth chapter gives some information on sound vibrations and waves, while Chap ix, headed "Preparatory Mathematics", provides a short summary of arithmetical procedure. The explanation of principles throughout the book is, in general, quite clear, and the reader is helped by some easily understood graphical illustrations. The treatment is not, however, carried to the stage of dealing with alternating currents, a knowledge of which will be essential before the reader can proceed to the consideration of the production of electrical oscillations and wireless waves. On the subject of elementary electricity and magnetism, the reviewer was not aware of the need of a further book on this subject, and at the published price of 12s 6d this volume would seem to be somewhat dear.

R. L. SMITH-ROSE

### Early Europe

*The Early Age of Greece* By Sir William Ridgeway  
Vol 2 Edited by A. S. F. Gow and D. S. Robertson Pp xxviii + 747 (Cambridge At the University Press, 1931) 30s net

IT is not usual for two volumes of the same work to be published thirty years apart. In Sir William Ridgeway's case the reason is that he began to write about the prehistory of Greece and found himself drawn into writing a prehistory of Europe, for the wide range of his theories led him to consider one district after another, Illyria, Italy, Central Europe, Ireland. The material to be studied was vast and constantly increasing, the angles from which he studied it were many, archaeological, sociological, religious, and literary. It is not to be wondered at if it grew unmanageable, especially for one of advancing years and failing eyesight. A lesser man would have given up the task altogether, but Ridgeway struggled on, wrote two or three lesser works dealing with fragments of his material or with subsidiary problems, and finally left behind at his death in 1926 an immensity of half-written work, in all stages from notes to proof-sheets, from which at last a selection has been published by the editors of this volume. Nearly seven hundred and fifty pages, illustrated with 158 figures, are by no means a contemptible fragment, we may judge how enormous the complete work would have been if it had ever seen light in the form the author meant it to have.

No 3260, Vol. 129]

As Mr. A. J. B. Wace points out in a short but excellent introduction, much of what now appears was written thirty years ago, and must be judged accordingly. There are echoes in it of controversies now dead and buried, and also, it must be admitted, passages which are instructive chiefly as showing what strange things passed for sociological evidence at the beginning of this century. This is particularly the case with the first chapter, "Kinship and Marriage". Ridgeway's general theory was that Greece was inhabited in very early times by a matrilineal population, of the race he terms Pelasgian, who were the authors of the Mycenaean culture on the mainland and were invaded by the Achaeans, a fair, tall people from the north, whose social structure was of the patrilineal type and whose nearest kin were the Kelts. It is difficult to say whether Ridgeway shows more acuteness here in refuting the opinion of M'Lennan that mother-right existed in historical Greece or lack of critical judgment in the arguments he advances for its presence among the 'Pelasgians'.

With regard to the other chapters, "Murder and Homicide", "Fetish, 'Totem', and Ancestor", and "Ireland in the Heroic Age", much the same criticism may be made, with this difference, that the material is more largely archaeological, and when archaeology was his subject, Ridgeway had an almost unique power of making the dullest details interesting. To say that his interpretation is often doubtful is not to deny that he gives his critics something definite and clear with which to agree or disagree. About half his ideas were magnificently right, and for these we may honour his memory and pass quietly over the other half, which were enormously wrong.

H. J. ROSE

### Dr. Huxley and Mr. Arnold

*Brave New World a Novel* By Aldous Huxley  
Pp v + 306 (London Chatto and Windus, 1932) 7s 6d net

IT is difficult to resist the conclusion that the writing of 'Utopias' is far more entertaining than reading them. This is probably due to the fact that the planning of a novel of the future gives an author an enhanced sense of power unobtainable from a novel of the present. The present is too full of the past not to limit that pleasant sensation, which is probably why so powerful a creator as Mr. Wells turned more than once to the future for his material.

It was inevitable that Mr. Aldous Huxley should sooner or later write a novel of the future. "Brave

R. I.

New World" is his second-best book, for he will never surpass "Antic Hay". It proposes to describe a scientifically organised world, in which, however, one cannot imagine any scientist of to-day being able to live and work successfully. It is throughout a parody of the scientific point of view—shifting it ever so slightly but sufficiently towards the ridiculous—coupled with an exposition of Mr Huxley's objections to what he conceives the scientific point of view to be. The reasons for these are two, of which the second will be described later.

In the first place, biology is itself too surprising to be really amusing material for fiction. If one wrote to-day a plain description of the work of Dr Butenandt on the male sex hormone, it would probably seem funnier than Mr Huxley's detailed opening chapter on the "Central London Hatchery and Conditioning Centre", where humanity is raised 'on model factory lines. But never mind. What happens to these Alphas, Betas, Gammas, Deltas, and Epsilons, who are, of course, people, produced and conditioned and reared all nicely class-conscious and contented?

Mr Huxley's genius here reveals itself. he knows their jokes, and they *are* funny, he also knows their sorrows and a cunning method for dealing with them, the ingestion of a pleasant dream-producing narcotic called 'soma'. He knows their pleasures, of which the foremost is promiscuous intercourse without fertilisation. Here he makes a slight mistake, for no young lady six hundred years hence would wear so primitive a garment as a Malthusian belt stuffed with contraceptives when a periodic injection of suitable hormones would afford her ample protection. But on mass entertainment, such as the 'Feelies'—heirs to 'Talkies'—he is quite sound.

In his search for dramatic relief Mr Huxley follows Voltaire. Borrowing from him the idea of "L'Ingénu", a nice, simple savage, he provides one, a poor boy born mistakenly of a European father and mother, the latter a Beta-minus and all named Linda, who had got lost on an exploratory excursion to the New Mexican reservation where Indians were allowed to remain on sufferance. While Linda here relapses into a horrible state of pre-scientific squalor, her son John discovers the works of W Shakespeare. Henceforth his speech is that of the bard.

Now, however, a terrible thing happens which brings us back to the second reason for saying that Mr Huxley is unable to do justice to the scientific point of view.

The savage is brought back to his kind in Europe and goes berserk in their brave new world. That is nothing. The terrible thing is this. Mr Arnold appears once more and goes berserk on Dr Huxley. (Everyone knows that Mr Huxley is the grandson of T. H. Huxley. He is also the great-nephew, I believe, of Matthew Arnold, and therefore the great-grandson of 'Arnold of Rugby'.)

Dr Jekyll and Mr Hyde are nothing to Dr. Huxley and Mr Arnold. Mr Arnold is always doing it. He did it in "Point Counter Point", he does it in "Brave New World". Dr Huxley, who knows and cares about biology and music, science and art, is once again ousted by this double of his, morbid, masochistic, medieval-Christian Mr Arnold takes charge of the last chapter of "Brave New World". The result is distressing. Nevertheless, this is a very great book.

CHARLOTTE HALDANE

#### Lavoisier

*Lavoisier* By J. A. Cochrane. Pp. xiii + 264 + 8 plates. (London: Constable and Co., Ltd., 1931.) 7s. 6d. net.

THE great majority of biographies may be divided into two classes: those that tell us what a man did, and those that show us what a man was. Mr Cochrane's life of Lavoisier is a very competent example of the former, in which the story flows smoothly and evenly, while a due sense of proportion is maintained throughout. If we are left at the end with the feeling that we still do not know what manner of man Lavoisier was, we must nevertheless gratefully acknowledge that the main facts of his life and work have never before been so adequately described in the English language. It has, indeed, been a reproach to us and to our American cousins that, while the adjudication between the relative claims of Lavoisier, Priestley, Cavendish, Watt, and others has always excited considerable interest among us, no complete or even moderately complete biography of the great Frenchman had been written in our tongue. This omission is all the more remarkable in that many historians of chemistry must have been in a position to repair it with very little additional labour to themselves. Happily, the reproach is now expunged, and though Mr Cochrane would probably be the first to admit that the definitive biography is still to be written, he deserves our warmest thanks for his clear and unbiased account of Lavoisier's career.

Though this is Mr Cochrane's first appearance

as a historian, he is already widely known as the author of several admirable little books on elementary science, in which his interest in the history of chemistry shows itself very plainly. The present book proves that his ability to write simply and attractively is allied to sound historical sense and critical judgment, and though he modestly says that he had hoped another pen than his own would have undertaken the task he set himself, most readers will feel that, within the same limits, no one could have achieved a more satisfactory result. He is at his best in plain narrative, as, for example, in his account of Lavoisier's early life and in his description of the circumstances of the arrest, trial, and execution, while his summary of Lavoisier's manifold scientific activities contains much that will be new, even to chemists.

On the question of Lavoisier's integrity in his claims to priority in the discovery of oxygen and of the composition of water, Mr. Cochrane sees no reason to dissent from the usual conclusion that he cannot be exonerated from the charge of attempting to pick the brains of Priestley and Cavendish, indeed, the facts are no longer in dispute, and one can only regret this 'moral twist' in a character that is in so many ways both noble and charming. We may frankly admit that Lavoisier was indebted to Priestley, to Beccaria, to Bayen, and to many others, and that he refused to acknowledge his indebtedness with any degree of completeness, but his unruffled calmness in the period of the Revolution and the bravery with which he faced the guillotine on May 8, 1794, go far to cancel the lapse. General nobility of character is not infrequently accompanied by curiously inexplicable shortcomings, and in the final reckoning Lavoisier's unselfish labours in the public welfare, not to mention his strict honesty in the *Ferme*, must surely be taken into account.

It is interesting to learn from Mr. Cochrane's pages that Lavoisier's marriage, which provided him with an ideal companion for his life and work, was agreed upon as a casual matter, undertaken to oblige his friend Paulz. The Controller-General, a man of fifty, had conceived an infatuation for Paulz's daughter Marie Anne Pierrette, a pretty child of thirteen with blue eyes, brown hair, and rosy complexion. Her father strongly objected to the match, and to put an end to a difficult situation (for the Controller-General was an extremely influential man), he suggested to Lavoisier that the girl would form a suitable bride for himself. Lavoisier obligingly consented, and the marriage took place in December 1771. Mme Lavoisier

brought her husband a *dot* of 80,000 livres, while his father gave him 250,000 livres as a wedding present. Since his mother had already left him 170,000 livres, the young couple entered upon their new life in very comfortable circumstances, and Lavoisier was able to carry on his scientific researches free from the shadow of financial cares.

Mr. Cochrane's story of the last few years of Lavoisier's life is an excellent, if sombre, piece of work. He states the facts without emphasis, but in so telling a manner that here, for a short time, we begin to feel that we see the man himself. Doom was in the air, and Lavoisier knew it, but he proceeded imperturbably with his experiments and refused to be frightened into giving up possessions that were legally his. He had sympathy with the Revolution in its early days, and never attempted to avoid payment of the heavy levies that the government made upon the wealthier classes, though he was careful to see that he paid no more than the law could properly demand. When at length he was arrested, with other members of the *Ferme*, he could no longer carry out original research, but he proceeded steadily with the composition of his "Memoirs of Chemistry." By the end of April 1794, the first two volumes were ready for the printer, and one of the last tasks of his life was to correct the proofs. The sands were now quickly running out, and in a few days Lavoisier's head fell on the scaffold, the victim immediately preceding him being his father-in-law Paulz, then an old man of seventy-five.

It is difficult to gauge the loss that science suffered through the untimely death of one of her most brilliant exponents, but Mr. Cochrane is not over-estimating the probabilities when he says that, if his wonted success had continued to attend him in the other problems he intended to explore, he would have anticipated many of the discoveries of the nineteenth century. Like Mr. Cochrane, we think it a strange fact that although Lavoisier was at the time of his death and for at least fifteen years before it one of the most eminent men in France, the general historian usually does not think it worth while to make any mention of him. Perhaps this little book may secure for Lavoisier his rightful position in the history of France, his position in the history of science is already established. The statue in the Rue Tronchet, miraculously undamaged by the German shell that shattered the end of the Madeleine, is a symbol of one who can never be dislodged from the halls of intellectual achievement.

E. J. HOLMYARD

## Short Reviews

*Théorie des fonctions algébriques et de leurs intégrales*  
Par Paul Appell et Prof Édouard Goursat  
Deuxième édition, revue et augmentée par Pierre  
Fatou Tome 1 *Étude des fonctions analytiques  
sur une surface de Riemann* Pp xxxv + 526  
Tome 2 *Théorie des fonctions algébriques d'une  
variable et des transcendentes qui s'y rattachent ,  
fonctions automorphes* Pp xiv + 521 (Paris  
Gauthier-Villars et Cie, 1930 ) 200 francs

VOL 1 of the present treatise is a revised edition of Appell and Goursat's well-known "Théorie des fonctions algébriques et de leurs intégrales" The second volume, contributed by the late M. Pierre Fatou, is an introductory but fairly comprehensive treatise on automorphic functions One of the most valuable features in the early part of this volume is a new and remarkably simple proof of the theorem, that a group of real linear transformations which has no infinitesimal transformation is properly discontinuous A determination of the fundamental domains of Fuchsian and Kleinian groups follows, and then the chief known properties of Fuchsian and Kleinian functions, and an account of the theta functions The only example of a group considered in detail, however, is, as in many previous treatises on automorphic functions, the modular one No insuperable difficulty exists in the way of extending this list considerably The whole treatise is written in clear and masterly style, it forms an admirable introduction to the classical work of Klein and Poincaré

*The Soil and the Microbe an Introduction to the Study of the Microscopic Population of the Soil and its Rôle in Soil Processes and Plant Growth* By Prof S. A. Waksman and Prof R. L. Starkey (The Wiley Agricultural Series) Pp xi + 260 (New York John Wiley and Sons, Inc., London Chapman and Hall, Ltd., 1931) 17s 6d net

"THE Soil and the Microbe" is a difficult book to review, for, knowing how much soil microbiology owes to the researches of the two authors, one is led to expect a high standard of excellence in a book from their pens, and this, unfortunately, is not the case Though apparently written for the elementary student or inquiring farmer, yet there is a doubt as to whether such readers would find the way smooth for a real understanding of the principles of soil biology To illustrate the unevenness of planning, the carbon dioxide cycle is first discussed in the foreword, then the nitrogen needs of the plants are mentioned on p. 14, where it is stated that these needs are furnished by the addition of inorganic substance or organic forms of nitrogen such as urea or guano, but it is not until much later in the book that there is any mention of the reason for supplying nitrogen in the form of urea or guano, or precisely what rôle microbes play in the transformation of such substances

The volume, however, should not be condemned out of hand, for undoubtedly it has its points, in that

it summarises a great deal of our knowledge concerning the chemical changes going on in the soil and is well illustrated, though Fig. 5 should undoubtedly be suppressed in any future edition, for it is either unintelligible or, if intelligible, incorrect

*Einführung in die Zytologie* Von Prof. Lester W. Sharp Mit Genehmigung des Verfassers aus dem Englischen übersetzt und vollständig neu bearbeitet von Prof. Robert Jaretsky Pp 733 (Berlin Gebrüder Borntraeger, 1931) 52 50 gold marks

SHARP'S "Introduction to Cytology" was first published in 1921 The present work is a translation and amplification of the second edition, which appeared in 1926 The considerable additions made by the translator, Prof. Robert Jaretsky, refer chiefly to the more recent literature, and are indicated by a 'J' on the margin of the page Discussions are added on protoplasmic inheritance, genic changes, mitogenetic rays, and various other topics, leading in some cases to a revision of the original author's point of view on such matters as the nature of the spindle fibres Some three hundred additional cytological papers are considered

The present work is a very good account of modern plant cytology, with reference not only to flowering plants but also to all the other plant groups By way of comparison, numerous references are made to the conditions in animal cells in connexion with such topics as Golgi apparatus, gametogenesis, syngamy, parthenogenesis, and chromosome structure This useful work for students and investigators ends with an extensive bibliography and a carefully compiled index

*La téléphonie* Par Robert Dreyfus (Collection Armand Colin section de physique, No 125) Pp 199 (Paris Armand Colin, 1931) 10 50 francs

ALTHOUGH the use of the telephone in everyday life is continually extending, yet the theory of its working is known to very few of its users Some of them know that it is connected with the name of Graham Bell, but beyond this their knowledge does not extend The object of this little book is to fill up the gaps in the knowledge of an otherwise well-educated man The subject is much wider than is commonly understood by the public In a book of this size, therefore, it is only possible to give a very brief account of the physical and mathematical difficulties that had to be overcome before the telephone attained its present perfection

To anyone with a knowledge of differential equations, the few mathematical formulæ given will be readily understood Other readers can omit the mathematics and yet gain quite an accurate knowledge of the telephone and of the transmission of electric signals through wires The description of automatic telephony is good, and so also is the account of the great advances made in long-distance transmission The purchaser of this book gets excellent value at a very small outlay

## Genetical and Biochemical Aspects of Anthocyan Pigments

By MURIEL WHELDALE ONSLOW

SINCE the publications of Willstatter and his co-workers upon anthocyan pigments during the years 1913-16, other investigators have turned their attention to this field of research. Though the later work has scarcely introduced any fresh facts of fundamental importance about this group of pigments beyond those already presented by Willstatter himself, yet it has given us much additional knowledge as to the distribution of the individual pigments among the flowering plants, especially in connexion with colour varieties of various species. The object of this article is to indicate how the chemical identification of the pigments may be correlated with certain broad aspects of the genetics of flower colour and the metabolic reactions connected with formation of anthocyan pigments in the plant itself.

From Willstatter's investigations the fact emerges that there are three commonly distributed anthocyan pigments—pelargonidin, cyanidin, and delphinidin.

Cyanidin and, especially, delphinidin appear also, according to Willstatter, in various plants as methyl ethers, certain hydroxyl groups being replaced by methoxyl groups. The positions, however, of the methoxyl groups were not defined precisely. Moreover, though the sugars of the glycosidal pigments were identified, the points of attachment of the sugar groups were not definitely ascertained.

The more recent investigations<sup>1</sup> include those of Karrer in Zurich and Robinson in Great Britain. Karrer and his co-workers have determined the positions of the methoxyl groups in such pigments as are methylated, also to some extent those of the sugars. Robinson and his co-workers have synthesised a number of benzopyrylium compounds, some of which have been identical with the natural pigments, and thus they have confirmed certain of Willstatter's conclusions. They have defined in many cases the position of the sugars and have synthesised some naturally occurring glucosides. Moreover, by elaboration of tests, they have made it possible to identify with relative ease various known anthocyan pigments in any given material.

For the purposes of this article, the presence of methoxyl groups and the kind and the position of the sugars are of subsidiary importance. The points at issue are concerned chiefly with the occurrence of the three main pigments.

Let us turn first to genetical problems. In the majority of horticultural plants which have been long under cultivation it is difficult to determine which species have been concerned in their origin. In a few cases, such as the sweet pea, Chinese primula, and snapdragon, it is relatively simple.

In the snapdragon (*Antirrhinum majus*) the pigment of the magenta flowers is cyanidin, and there is no doubt that this is the pigment of the original, wild, magenta-flowered type. About thirty years ago the most important of recent 'breaks' in *Antirrhinum* appeared—rose doré—a variety now catalogued under many names, such as coral, salmon pink, etc. Genetically, rose doré is hypostatic (recessive) to magenta, and there is a factorial difference. Though not yet isolated, there is no doubt that the flowers of rose doré contain pelargonidin. The stems, petioles, and leaves often develop pigment too; in the original magenta type it is cyanidin, in the variety, pelargonidin. Here, then, we have the creation from a plant producing cyanidin of another which produces pelargonidin instead. Moreover, it should be realised that the power to produce one or the other pigment may be limited to the epidermal layer of the plant. In some horticultural types and varieties two or more pigments may be present together, though one usually predominates. Such complications are eliminated from the present discussion, especially as the segregation of pigments is usually complete.

Now a similar case to that of *Antirrhinum* has long been obvious from Willstatter's original results. He found the blue cornflower (*Centaurea Cyanus*) to contain cyanidin, its pink variety, pelargonidin. Though the genetics of the cornflower may not have been demonstrated in a practical way, it is clear to a geneticist that there is a factorial difference between blue and pink, and that pink is hypostatic.

Another case is the blue flower of *Hyacinthus orientalis*, which contains delphinidin. Though the origin of many horticultural bulb plants is doubtful and has often been kept secret, one must suppose the colour of the original *H. orientalis* to have been blue. The pink variety contains, again, pelargonidin, and cyanidin is claimed for intermediate varieties. In Nature, too, a pink variety of the wild hyacinth (*Scilla nutans*) may be found occasionally. In the latter we have undoubtedly a phenomenon of variation alone. In blue *Campanula* delphinidin is reported, and we cannot doubt that the original type was blue. Again, a hypostatic pink variety exists and contains pelargonidin. Thus from a delphinidin type also have arisen varieties containing pelargonidin and, sometimes, cyanidin. This true red (pelargonidin)

group of the geneticist, hypostatic to cyanidin and delphinidin groups, is obviously present in a number of cultivated plants, such as the sweet-william, Chinese primula, stock, phlox, carnation, sweet pea, and *Clarkia*. To determine when it is a true sport (*Antirrhinum*, Chinese primula, and sweet pea) and when it may result from species crossing is, however, difficult.

Now the interesting question arises whether, conversely, starting with pelargonidin, the power to form cyanidin may arise by variation, or, starting with cyanidin, the power to form delphinidin (all pigments again may be limited to the epidermis). Evidence in support of this supposition is difficult to acquire. The varieties of types under long-standing cultivation may show, among them, all three pigments, but since there is often uncertainty as to the outward appearance of the original type, so there is also uncertainty as to its pigmentation. Thus in the sweet pea, of which the original type resembled 'Purple Invincible' and in the Chinese primula, where the original type is known, we have not yet been informed as to their pigmentation. Such types may have contained either delphinidin or cyanidin, or both. In the aster, chrysanthemum, gladiolus, gloxinia, phlox, tulip, and others the problem is even more difficult. There is, however, a case where it would appear that a pelargonidin type has given rise to a cyanidin variety. Such is the garden nasturtium (*Tropaeolum majus*). The orange-red type contains pelargonidin, purple-red varieties, which are hypostatic to the type, contain cyanidin.

Thus, summing up, we may say that loss of one series of factors leads to loss of power of oxidation in the phenyl ring, so that instead of delphinidin, cyanidin is formed, and instead of cyanidin, pelargonidin. There is little doubt, too, that the reverse effect takes place. Thus we may express as the loss of a series of factors which inhibit oxidation, in other words, loss of another series of factors leads to increased oxidation. So that, instead of pelargonidin, cyanidin may be formed, and instead of cyanidin, delphinidin.

The occurrence of a more oxidised pigment in a hypostatic variety is also to be found in the inheritance of flavone pigments in *Antirrhinum*. Two varieties, ivory and yellow, exist, and of these ivory contains apigenin, yellow, luteolin.

There is a factorial difference between the varieties, and ivory, moreover, is epistatic (dominant) to yellow.

Now the question arises as to what may be the significance of the facts so far quoted. I have already pointed out<sup>2</sup> that evidence in general indicates the origin of anthocyan pigments from condensation of residues of amino-acids after de-amination.

There are three classes of aromatic compounds which may be synthesised from such residues, the flavone pigments,<sup>\*</sup> the anthocyan pigments, and the tannins. Flavone pigments are universally distributed in the tissues under all conditions. Hence it is likely that they are products of de-amination and condensation under the usual conditions of growth and development. Anthocyan pigments are only formed under special conditions. Finally, the tannins only arise in a certain type of plant.

Upon the precise reactions of condensation leading to the formation of anthocyan pigments it is idle to speculate. The phenyl ring, we would assume, has its origin from tyrosine or phenyl-alanine. The phloroglucinol ring, possibly, from short-chained residues of aliphatic amino-acids, or again, possibly, from hexose. By oxidation, either by enzymes or chemical agents, hydroxyl groups are readily introduced into the phenyl ring in a position *ortho* to that of an existing group. Clearly, the occurrence and segregation of pelargonidin, cyanidin, and delphinidin is a matter of loss or gain of power of oxidation or reduction.

It is obvious from the foregoing that the wide range of coloration in flowers is to some extent due to the pigment involved. Summarising on very general lines, one may say that pelargonidin flowers (though these are rare in natural species) incline to shades of scarlet, cyanidin flowers to shades of crimson or purple-red, delphinidin flowers to shades of blue or purplish-blue. But there are many exceptions to such a classification. The scarlet poppy, the magenta rose, and the blue cornflower contain the same pigment, cyanidin. In the Chinese primula, two varieties, blue and magenta, exist having the same pigment.

The idea has prevailed for a century or more that the colour of a flower may be changed by the presence of various substances in the petals, such as acids, alkalis, iron salts, and other compounds. Willstätter showed that the blue colour of the cornflower is due to a potassium salt of cyanin. He also constantly emphasised his view that the colour of the flower or fruit may be modified by accompanying substances in the tissues. Recently, Robinson<sup>3</sup> has brought forward the idea of the existence of co-pigments in many cases, that is, a variety of substances occurring in the plant which, entering into loose combination with the anthocyan pigments, modify their colour. Such a substance may represent a factorial difference between varieties.

So much for variation in colour. A suggestion can also be made here in connexion with the cause of albinism. In *Antirrhinum* there are two forms of albino in regard to anthocyan pigments, namely, ivory (including the hypostatic yellow) and white. The ivory contains flavone pigment, the white has none. Ivory and white (of correct constitution) crossed together will produce the magenta type. That is, ability to form flavone pigment is one essential for anthocyan production, the other is a factor borne by white. Such white-flowered plants are always stunted and poorly developed.

\* The expression flavone pigment is collective and includes both flavone and flavonol.

They contain no flavone pigment, and hence can never form anthocyan pigment, though not necessarily derived from the yellow pigment, anthocyanin production depends on its presence

It is reasonable to suggest that some aromatic component of the protein is entirely absent from the white-flowered plants. Hence neither anthocyan nor flavone pigment can be formed. A different cause for albinism must be postulated for the ivory variety, though there is no indication at present as to what this may be. Two kinds of albino, containing between them the elements essential for the production of anthocyan pigment, occur in the sweet pea and many other plants, but in these cases they are usually indistinguishable to the eye.

There is yet another form of variation among cultivated plants of rather a different nature from those we have already considered. In this the type has flowers, either free from anthocyan pigment or only slightly tinged, whereas the variety is fully coloured. That is, loss of a factor gives rise to a fully pigmented, hypostatic variety. The origin of the red variety of the sunflower (*Helianthus annuus*) from the yellow type affords an example, so also does the purple-leaved (copper) beech.

Just such a phenomenon as the above mentioned, that is, the appearance or non-appearance of anthocyanin, is characteristic of the flowering plants as a whole. The flowers of certain species form very little or no anthocyan pigment, while it is abundant in the flowers of others. It is difficult to make any suggestion as to what may be the chemical interpretation. It is conceivable that presence of sugar in the tissues may prevent the de-amination in inhibited types, or that excess of sugar may bring about condensation, as is probably the case when anthocyanin develops as the result of artificial sugar feeding. If so, then the factors concerned are correlated with some metabolic cycle other than that of pigmentation.

Before we leave the above variation among species one more point may be made, namely, the resemblance of the phenomenon to the distribution of autumnal anthocyan pigment in leaves, for the latter also is present in some species and absent from others. In fact, the autumnal coloration of leaves may be regarded as quite analogous to the pigmentation of petals. In each case the organ is senescent, it has ceased to assimilate and is gradually becoming detached from the parent plant. Desiccation is enhanced in the petal by the unprotected condition of the tissues against loss of water, in the autumnal leaf by the decreased water absorption from the soil owing to low temperature. An autumnal leaf developing anthocyan pigment can be regarded as a petal of very coarse texture. When anthocyan pigments are not developed it is yellow, as is also a petal which owes its colour to plastid pigment and has not the power to form anthocyan pigment.

Finally, some additional points of interest are connected with a consideration of the relationship of the particular anthocyan pigment formed in a plant to the accompanying flavone pigments and

other aromatic compounds in the same plant. If we ascertain the relative frequency of occurrence of cyanidin and delphinidin among the plants investigated, we find the values to be approximately as follows

|                                               | Plants containing cyanidin | Plants containing delphinidin |
|-----------------------------------------------|----------------------------|-------------------------------|
| Where isolation of pigment has been achieved  | 12                         | 12                            |
| Where pigment is identified by reactions only | 61                         | 60                            |

Thus plants appear to form an anthocyan pigment having the three hydroxyl groups characteristic of gallic acid as frequently as one with the dihydroxy grouping characteristic of catechol.

Now an outstanding fact of importance in connexion with aromatic compounds in the flowering plants is the distribution, in about 63 per cent of the natural orders, of the catechol oxidase system involving the presence of substances containing the dihydroxy grouping of catechol. From the remaining plants catechol derivatives are absent, pyrogallol compounds being frequently formed instead.

For all cases available I have made a record of the type of anthocyanin formed and the presence or absence of the catechol oxidase in the same plant. It is clear from the outset that the presence of the latter cannot always be associated with formation of cyanidin and its absence with formation of delphinidin, since the frequency of occurrence of cyanidin to that of delphinidin is 1.1, while that of oxidase to non-oxidase plants is almost 2.1. Such a conclusion is also apparent on analysis of the cases of species producing delphinidin, instead of being universally without oxidase, some contain oxidase, while others are non-oxidase plants. Hence on broad lines there is apparently no indication that plants producing catechol compounds always produce cyanidin.

Nor can any consistent relationship be detected between the anthocyan and flavone pigments of individual plants. Thus, for example, both flavone and flavonol pigments occur in plants

But all natural anthocyan pigments, on the simple reduction relationship, are related to flavonols, none to flavones.

In *Rosa gallica* and the wallflower there is a certain symmetry in the relationship of flavone to anthocyan pigment, the former being quercetin, the latter cyanidin, yet in other cases, such as *Delphinium* (kämpferol, delphinidin), *Viola* (quercetin, delphinidin), and *Antirrhinum*, there is no such connexion.

In varieties of *Antirrhinum* the four pigments, cyanidin, pelargonidin, apigenin, and luteolin, are formed. But there is no correlation between their presence in the epidermis. Cyanidin or pelargonidin can be found either with apigenin or luteolin.

General considerations would suggest that possibly in the flower flavone pigments result from

de-amination connected with growth and development, anthocyan pigments with de-amination connected with senescence.

<sup>1</sup> The investigations of Karrer and his co-workers are published in *Helv. Chim. Acta*, those of Robinson and his co-workers in *J. Chem. Soc. and Biochem. J.* Details of the data on genetics can be found in the *J. Genetics* and Onslow's "Anthocyanin Pigments of Plants".

## The Eruptions in the Andes

By Dr CHARLES DAIVSON

EARLY in the morning of April 10, eruptions began in several volcanoes of the southern Andes, most of which were supposed to be dormant or but rarely in action. The volcanoes affected, from north to south, are Tupungato, Overo, Tinguirrica, Peteroa, Descabezado, Las Yeguas, and Quizapu. Their heights diminish southwards, from 21,810 ft for Tupungato to 11,342 ft for Las Yeguas. All of them were in action simultaneously, though the distance that separates the extreme mountains is about 200 miles.

The principal feature of the eruptions is the great amount of the solid materials ejected. Loud explosions were heard at Santiago on the west side, and throughout the department of San Rafael on the east side, one hundred miles or more from the nearest volcano. But they were evidently not to be compared with those during the eruption of Krakatau in 1883, the sounds of which were heard at several places more than 2000 miles from the island, and at one place 2968 miles distant. Some observers in an aeroplane crossed the great crater of Las Yeguas (apparently on April 12). Every half-minute, loud explosions occurred within it, and blocks weighing many tons were thrown upwards more than 200 ft. These, it was said, gave the impression of being pulverised in mid-air.

During the three days of activity—the eruptions had almost ceased on April 13—all the towns near the volcanic zone were in a state of semi-darkness owing to the steady fall of fine dust and ashes. On the west side, the country from Santiago to Talca was covered with a layer of whitish dust, in places more than two inches deep. On the east side, the fall was much heavier. In the department of San Rafael, the layer of dust was a foot in depth, in other places more than two feet, and in one nearly three feet, so that trains were stopped from running. Even at Montevideo, about 850 miles from the nearest volcano, there was a steady fall of dust for many hours. Over Buenos Ayres (730 miles), it is estimated that more than 3000 tons of debris have fallen. The whole country there is coated with grey dust, so that cattle have to be fed with hay and artificial foods. Even if the average thickness of the dust over the whole area of deposition were no more than one-tenth of an inch, the total volume of the fallen dust would be about five cubic miles.

Several villages in the province of Mendoza were shaken by earthquakes, the stronger, no doubt, among many hundreds felt in the neighbourhood of the volcanoes. The shocks that accompany a volcanic eruption, though sometimes destructive

within a small area, are seldom felt more than a few miles from their origins. Occasionally, as in Hawan in 1868 and Sakura-jima in 1914, a tectonic earthquake strong enough to be registered all over the world may occur in the immediate neighbourhood of the volcano, but such disturbances are rare.

About one hundred years ago, on Feb. 20 1835, an earthquake of somewhat similar type overthrew Concepcion, and with it a long stretch of the Chilean coast was uplifted, in one place by 10 ft. One month before this, as Darwin describes in his great memoir, "On the Connexion of Certain Volcanic Phenomena in South America",\* eruptions occurred in three volcanoes, Osorno, Aconcagua, and Coseguina, all beginning within six hours. The first two mountains are separated by 550 miles. The third is so distant from either that, as Darwin says, we cannot be too cautious in assuming that the phenomena were connected. At the moment of the Concepcion earthquake, the volcanoes of Osorno and Minchinmadom, 150 miles apart, burst into action. Some months later, on Nov. 11 of the same year, a severe earthquake occurred at Talcahuano, the port of Concepcion, and on the same day, Osorno and Corcovado, separated by 205 miles, burst into violent action.

To us at a distance, a question of great interest is whether the eruptions will be followed in due time by such wonderful sunsets as were observed all over the world for months after the Krakatau eruption of 1883. With regard to the amount of dust projected into the atmosphere, there can be little doubt. The question is whether enough could rise to heights of from eight to ten miles. As Capt. Cave remarks in a letter to the *Times* (April 14), the explosions seem to have been less violent than those of Krakatau. On the other hand, the height of Krakatau was 2623 feet, while the Andean volcanoes rise from two to three miles higher. On April 13, Capt. Ralph Wooten, the U.S. Air Attaché at Santiago de Chile, flew across Quizapu at an altitude of 14,000 ft. He estimated that the smoke column was then reaching 5000 ft. above the crater, but he considers that, on April 10, at the moment of greatest activity, it must have risen to a height of 30,000 ft. If this estimate is correct, or nearly so, it seems possible that, within a few months, sunset glows may be visible in Great Britain. The eruption of Krakatau, it will be remembered, occurred on Aug. 26–27. The sunset glows were not observed in England until the end of November.

## Obituary

MR RICHARD SOUTH

MR RICHARD SOUTH was born in July 1846 at Cochran Terrace, Marylebone, the site of which has long since been occupied by the old Great Central Railway. Little is known of his early life beyond the fact that he was educated at a private school at Reading. He died at his home in London on Easter Monday, March 28, after a short illness which terminated a long period of failing health.

The earliest contributions made by Mr South to the entomological journals, in 1874-78, concerned his captures in the Mill Hill district, Hendon, which appears at that time to have been a very rich locality. Up to 1890 he contributed sixty notes and articles to the *Entomologist* and the *Entomologists' Monthly Magazine*, dealing with a great variety of subjects. The most important were his "Contributions to the History of the British Pterophori", published at intervals from 1881 until 1889, which added considerably to existing knowledge of the British plume-moths. He early developed a particular liking for the Microlepidoptera, and many of his notes concern this large group, especially the Tortricidae, others are faunistic, for example, "The Lepidoptera of the Outer Hebrides, Shetland and Orkneys" (*Entom* pp 25, 28, 98, etc., 1888), some deal with migration, others with collecting results, variation, etc. His "Notes on the Genus *Lycæna*" (*Entom*, pp 1, 49, 73, 121, 1887), in which the variation of a number of species was described in detail, led him into an acrimonious discussion of the species-concept, upon which his views were somewhat unorthodox. This was not the only matter which brought him into conflict with other lepidopterists of this period, for a year or two earlier, in 1884, in co-operation with those responsible for the *Entomologist*, he produced a "Synonymic List of the British Lepidoptera". This was designed to act as a label and exchange list and to replace Stainton's, which was long out of date but still the only one available. In the nomenclature used he did his best to apply the law of priority, which necessitated changing a very large number indeed of the names commonly employed—to the very great annoyance of every working lepidopterist of the day. Nevertheless, the list is in constant use even now.

About this time Mr South's interest in the Microlepidoptera appears to have brought him into touch with John Henry Leech, to whose "British Pyralidae" (1886) he contributed a number of notes. The association developed, only to be broken by the death of Leech in 1900. During this period he acted as a kind of curator and adviser to Leech, whose interest in the Far East eventually led to the publication of the "Butterflies of China, Japan and Korea" (1882-1894), in the production of which all the spade work was done by South. This was supplemented by the publication elsewhere of the descriptions of a very large number of eastern Heterocera new to

science. In order to acquire an outlet for this work, Leech purchased the *Entomologist* in 1890 and appointed South to the editorship, which he retained until 1924. For many years after Leech's death, South continued to work at the Far Eastern fauna, chiefly in collaboration with Wileman, jointly with whom he published a number of papers.

In 1906 there appeared South's "British Butterflies", the first of the three handy little volumes of the Wayside and Woodland Series, which are now standard works on our British Lepidoptera, and have made his name familiar to amateur and professional alike. The volumes on the moths appeared in the following years (1907 and 1908). Although the appeal of these volumes was directed to the beginner, both text and illustrations were so excellent that they at once achieved an immense and deserved popularity, which is not likely to desert them for many years to come. Undoubtedly it is by these volumes and by his long and successful editorship of the *Entomologist* that Mr South's name will be remembered amongst British lepidopterists long after those of us who had the pleasure of knowing him as a charming and courtly gentleman, an enthusiastic and painstaking entomologist, an excellent companion, and an honoured personal friend, have passed over where he has so lately gone.

MR ST GEORGE LANE FOX PITT

By the recent death of Mr St George Lane Fox Pitt at his residence in South Eaton Place, at the age of seventy-five years, we lose one of the few remaining pioneers of electric lighting. He was the second son of Lieut-General A H Lane Fox Pitt-Rivers, a distinguished anthropologist and archaeologist, who presented his collections to the University of Oxford. In his early days, Lane Fox Pitt (his father took the surnames of Pitt-Rivers for himself and that of Pitt for his family) devoted himself to scientific research and mechanical invention. In 1878 he took out a patent for the method of running incandescent lamps in parallel. This patent, being one of the earliest in electric lighting, has been often quoted in the law courts.

He also took a leading part in improving incandescent lamps. The early glow lamps had carbon filaments in a vacuum glass bulb. These filaments were connected with the mains by 'leading-in' wires passing through the glass. These leading-in wires were made of platinum, which has the same thermal coefficient of expansion as glass. Great difficulty was experienced in connecting the filaments and the platinum wires. The connexion was at first a simple mechanical one, the filaments being merely clamped to the wires. This joint, however, was not satisfactory, as it often worked loose. One of the earliest methods Lane Fox Pitt employed to get over this difficulty was to use a hollow carbon tube into which the platinum wire was inserted.

In 1883, Lane Fox Pitt took out an important patent for altering the pressure of electric supply by means of a motor dynamo. This was one of the earliest types of transformer. He was also one of the first to advocate a public supply of electricity from central stations.

Lane Fox Pitt was one of the early active workers in the Society for Psychical Research, and wrote several books on science, philosophy, education, and social problems. He contested three elections in the Liberal interest, but without success. He married, in 1899, Lady Edith Douglas, daughter of the eighth Marquess of Queensberry.

We regret to announce the following deaths

Prof W R Dron, Dixon professor of mining in the University of Glasgow since 1923, on April 16, aged sixty-three years.

Sir Patrick Geddes, formerly professor of socio-

logy and civics in the University of Bombay and of botany at University College, Dundee, who was well known for his work for education and the study of sociology, aged seventy-eight years.

Dr Alfred Hay, sometime professor of electro-technology, Royal Indian Engineering College, Coopers Hill, and afterwards at the Indian Institute of Science, Bangalore, on April 13, aged sixty-six years.

Prof G M Robertson, professor of psychiatry in the University of Edinburgh, and physician superintendent of the Royal Edinburgh Hospital for Mental and Nervous Disorders, on March 28, aged sixty-eight years.

Mr Eustace Short, of the firm of Short Brothers, of Rochester, who was a pioneer in the design and construction of aeroplanes, on April 8, aged sixty-two years.

Prof A L Urquhart, O B E, professor of pathology at the University of Cairo, on March 28.

## News and Views

### In Honour of Darwin

ON April 19, 1882, science sustained an irreparable loss by the death of Charles Darwin in his seventy-fourth year. On April 26 of that year his mortal remains were borne on the shoulders of his comrades to his last resting-place at Westminster Abbey, where they were laid close beside the graves of Sir John Herschel and Sir Isaac Newton. At the end of last year we commemorated the centenary of the start of Darwin's famous voyage in the *Beagle*, three years after his return he married, and in 1842 settled at Downe, Kent. It is no exaggeration to say that the work which emanated from that quiet English home during the succeeding forty years proved more effectual than any other in making the nineteenth century illustrious. The general facts upon which the principle of evolution by natural selection is based—the struggle for existence, survival of the fittest, and heredity—were all well known before Darwin's work. His claim to everlasting memory rests upon the many years of devoted labour whereby he tested the idea in all conceivable ways, amassing facts from every department of science, balancing evidence with the soundest judgment, and at last astonishing the world as with a revelation by publishing the completed theory of evolution by natural selection. Of very few men in the history of our race can it be said that they not only enlarged science but also changed it, not only added facts to the growing structure of new knowledge but also profoundly modified the basal conceptions upon which the whole structure rested and of no one can this be said more truly than of Charles Darwin. It is a striking tribute to his memory that April 19 was declared a public holiday in the U S S R in honour of the author of the "Origin of Species."

### Research Scholarships at the Royal College of Surgeons

At a meeting of the Council of the Royal College of Surgeons of England on April 14, the president of the

College, Lord Moynihan, announced an important benefaction from the trustees of the late Viscount Leverhulme. In presenting £1000 to provide "Leverhulme Scholarships" in surgical research, the trustees expressed the hope of being in a position to make a similar donation from year to year. The gift thus announced permits the Council of the College to go forward with an ambitious scheme of experimental research made possible by the munificence of Sir Buckston Browne, who a year ago gave £100,000 to build, equip, and endow a Research Farm at Downe, Kent. The Buckston Browne Research Farm, which is approaching completion, has been built on land which adjoins the home and grounds of Charles Darwin, which Sir Buckston acquired in 1928 and conveyed to the British Association, to be maintained as a memorial of Darwin and to be used for the advancement of science. The Leverhulme Scholarships are to be given to aid young men and women who are selected by the Council of the College to investigate surgical problems at the Buckston Browne Research Farm. Besides the laboratories at Downe, the Council has also equipped laboratories in the College, Lincoln's Inn Fields. These are now fully occupied. Lord Moynihan succeeded in obtaining temporary scholarships for men working in the College laboratories from Sir Bernhard Baron, Lord Beaverbrook, and the late Lord Melchett. The Council also sets aside annually from its own funds £500 to provide a College fellowship in surgical research.

### Australian Observatories

FOR reasons of economy, the Australian Premiers' Conference has decided that there shall in future be only two national observatories instead of the existing five (Perth, Adelaide, Melbourne, Sydney, and Canberra). The total saving cannot be great, since the combined revenues of all five from governmental sources amount to less than £15,000 per annum; nevertheless, three are to be closed. The Premiers' Conference has asked Sir Thomas Lyle, Dr A C D.

Rivett, and Prof O U Vonwiller to advise it as to (1) the locations of the two to be retained, (2) the disposal of existing equipment, and (3) the probable initial cost, if any, of supplementing existing equipment at the two chosen observatories, the estimated cost of maintenance of these two, and the best means of disposing of outstanding work in connexion with the Astrographic Catalogue, to which work several of the States were committed many years ago. Maybe two institutions, if thoroughly well supported, will be more effective than five inadequately maintained, but many will view with misgiving a decision of this kind based mainly on a desire to save money.

#### Early Man in East Africa

THE conclusions at which Dr Leakey, Dr H Reck, and Mr A T Hopwood arrived in their recent investigation of the Oldoway Beds in relation to the antiquity of the human skeleton found in these deposits would appear to have received confirmation by a find at Kanam, a small native village on Lake Victoria. Here Dr Leakey, it is reported in a dispatch from Nairobi which appeared in the *Times* of April 19, has discovered a lower jaw of *Homo sapiens* in deposits containing pre-Chellean implements and teeth of the same species of *Dermotherium* as was discovered at Oldoway. At Kanam, however, the beds in which the find was made correspond with the oldest of the Oldoway beds, whereas Oldoway man was found in Bed No 2. Other finds reported from early Pleistocene deposits at Kanam are fragments of three human skulls, apparently washed out from deposits containing Chellean tools and remains of *Elephas antiquus* and *Hipparion*. At first sight, this find on Lake Victoria carries *Homo sapiens* back a stage further than the Oldoway discovery, but a more detailed account of the deposits and the conditions of the find must be awaited before a certain conclusion is possible. The difficulty of accepting a skeleton found entire, as was Oldoway man, as contemporary with the alluvial deposits in which it occurs—a difficulty already pointed out (*NATURE*, Feb 27, p 312)—is stressed in the current number of *L'Anthropologie* (t 42, p 214), where it is also suggested that the general conformation of the Oldoway skull points to an affinity with the modern Masai.

#### Liquid Carbon Dioxide in Ocean Water

IN an interesting article (*C R Acad Sci Leningrad*, 1931), the eminent Russian geochemist, V Vernadsky, directs attention to the fact that the conditions of temperature and pressure in the depths of oceans should necessitate the existence there of carbon dioxide in a stable liquid state. The chemical interrelations of water and liquid carbon dioxide are as yet unknown, but they must play an important part in the life of organisms at great depths. Their gaseous metabolism should differ greatly from that of organisms inhabiting the surface layers of water, where the expired carbon dioxide can exist as a gas. It is known that the lower limit of plankton is about 200 metres from the surface, while sunrays penetrate very much deeper, and photo-synthesis is theoretically

possible for red algae down to 400-500 metres. They do not, however, occur below 200 metres, which means that the limit of their distribution is not governed by the lack of active light rays, but probably coincides with the zone where the gaseous state of carbon dioxide becomes unstable and the liquid state appears. Again, the conditions of gaseous metabolism of numerous organisms in the mud at the bottom of the oceans should be highly peculiar, the gases present there constituting an atmosphere very different from that in the mud of shallow waters. The interesting fact discovered more than a hundred years ago by Biot that the bladder of deep-sea fishes contains pure oxygen, which, according to later discoveries, is produced by special glands, has always remained a physiological puzzle, but it is possible that this is also connected with their life in the zone where only liquid carbon dioxide exists. It is legitimate to ask, for example, whether the oxygen in the bladder is not the result of decomposition of liquid carbon dioxide. All these considerations and examples serve to stress the necessity of organising systematic investigations on the distribution of gaseous and liquid carbon dioxide in different zones of oceans.

#### The Willis Navigating Machine

AT a recent meeting of the Royal Astronomical Society, the capabilities of this ingenious instrument (aviation type), designed by Mr E Willis for the solution of spherical triangles, were demonstrated by Dr L J Comrie, Superintendent, H M Nautical Almanac Office. Mechanically, the instrument is a combination of an alt-azimuth and equatorial with five graduated circles corresponding to altitude, azimuth, latitude, declination, and hour angle. The principal problem in nautical astronomy is the calculation of the altitude and azimuth of a heavenly body from given values of the latitude, declination, and hour angle. These quantities are set on the corresponding circles and the machine at once gives the appropriate altitude and azimuth, which can then be used, in conjunction with the altitude from a sextant observation, to give the position line on the chart. This is only one of the many problems that the instrument can solve. In the type of instrument designed for aeronautical navigation, the circles read to five minutes of arc, which is sufficiently accurate in practice, being of the same order of accuracy as readings made with a bubble-sextant. The instrument designed for marine purposes is larger and more accurate, in this type the graduated circles read to one minute of arc. In aeronautical navigation, the quick reduction of observations is an essential desideratum, and the Willis machine gives complete satisfaction in this respect. The instruments are manufactured by Messrs Heath and Co, New Eltham, London, S E 9.

#### Insulators for Switchgear and Busbars

AT present there is a great demand for insulators for high voltage outdoor isolating switchgear. With a pressure of 132,000 volts and a high mechanical stress, the greatest care has to be used in their design, as any breakdown in the continuity of supply of a

large amount of electric power may disorganise many factories. In the usual design of high pressure insulators, cement is used inside the porcelain to join the shells and the metal parts together. Any expansion of the cement imposes bursting stresses on the porcelain, which often cracks. Some manufacturers, with this danger in view, sacrifice some of the mechanical strength of the joint by inserting elastic layers of bitumastic paint and, in addition, dilute the cement with sand to reduce the percentage expansion. Continental engineers have recently been using insulators in which internal cement layers have been entirely eliminated. They consist of porcelain cylinders carrying suitable projections called rain-sheds and containing no cement layers. The elasticity of the flanges takes up the expansion of the cement. This cylindrical construction has been developed in Great Britain by Messrs Steatite and Porcelain Products, Ltd, who export them abroad. They now supply 132 kv cylindrical type switchgear insulators for the substations of the latest section of the British grid. The disadvantage of the wide base customary with this type of insulator has been overcome by the introduction of an ingenious series of flanged castings, so made that all the standard methods of fixing now in use can be applied to the cylindrical insulators. They are so designed that the greatest possible amount of surface is exposed to natural cleaning. The use of these new insulators on the grid will, during the next few years, give an opportunity of comparing them with the older type under working conditions. Their increasing use on lower voltages should help towards the electrician's ideal of complete continuity of service.

#### Boiler Plant in Power Stations

To the electrical engineer a knowledge of the thermal efficiency, operating costs, and trustworthiness of the boiler plant in his power station is almost as important as a knowledge of his electrical machines. J. Bruce read a lengthy paper on this subject on March 10 to the Institution of Electrical Engineers. He had, however, to omit the discussion of flue gas, dust, and sulphurous fume extraction, as the Chimney Emissions Committee has not yet reported. He pointed out that a study of present-day American conditions leads to the general conclusion that the best American generating stations have a higher thermal efficiency than those representative of the best average British practice. A number of American generating stations produce a kilowatt hour for a heat expenditure of less than 14,000 B.Th.U. This is due to better boiler plant and to the higher grade of employee used in operating it. The Detroit Edison Company, for example, has a boiler-house efficiency of 87 per cent. In the United States, when a station uses high steam pressure, it either uses a pressure of about 600 lb per square inch or one of about 1300 lb per square inch. At the present time, there are 15 boiler units operating successfully and with no serious troubles in the neighbourhood of the higher pressure. Large boiler units capable of evaporating one million pounds of water per hour are being successfully

operated. The capital cost of the boiler plant required increases rapidly with the pressure when it is above 600 lb per square inch. Consequently, when coal is cheap the interest on the increased capital cost may more than offset the gain in the heat efficiency. America has the advantage over Great Britain that combustion equipment can be developed for a particular quality of coal owing to the geological characteristics of the coal being uniform over wide areas. British practice, although not obtaining such excellent thermal results, has yet made good progress of recent years.

#### Manufacture of Electric Lamps

ONE of the exhibits at the Faraday Centenary Exhibition last September which attracted much attention was that showing some of the operations in the manufacture of electric lamps. Only a few of the operations could be demonstrated, but much further information on the subject is contained in an article on "The Mass Production of Electric Incandescent Lamps" in *Engineering* for March 25. The article contains a description of the new Wembley Lamp Factory of the General Electric Co., Ltd, which has a capacity of 25,000,000 lamps a year. All the machines used are illustrated, and many interesting facts are given about the manufacture of the components of a lamp. The tungsten for the filament is obtained from the ore scheelite. It is first prepared in the form of powder, which is subjected to very great pressure and then treated in an atmosphere of hydrogen, first at about 1200° C, and then at about 3000° C. Sixty drawings are required to reduce the original 1 mm rod to a filament 0.015 mm in diameter, and a tungsten bar  $\frac{1}{4}$  in square and 10 in long can be drawn into 15 miles of filament. The leading-in wires, which used to be of platinum, are now of copper-covered nickel-steel. The important operation of exhausting the lamps and then filling them with gas is done on capstan machines, each holding twenty-four lamps. Vacuum pumps reduce the pressure in them to a few thousandths of a millimetre of mercury, heat from an oven drives off moisture and adsorbed gas, and, while still hot, the lamps are filled with a mixture of nitrogen and argon, the internal pressure when cold being about two-thirds of an atmosphere.

#### The World's Natural History Societies

THE diffusion of scientific interests in the world, as indicated by the numbers and distribution of natural history societies, has been studied by Enrique Sparrn (*Bol. Acad. Nac. Cienc. Buenos Aires*, vol. 31, p. 171, 1931). Confining the inquiry to the larger societies, with a membership of 500 or more, the author finds that the world total amounts to 116 societies, of which 52 are devoted to natural history in general, 34 to zoology, 14 to botany, and 16 to geology. From a geographical point of view, natural history interests would appear to be tolerably restricted, for when we have mentioned 83 European societies with a total membership of 132,182 individuals, and 30 American societies with a membership of 160,947, there remain only 2 societies in Asia with a membership of 1938,

and one in Australia with a membership of 550. In this short note it is impossible to analyse all the naturalist sciences, but since zoology is by far the most populous, it may be taken as illustrating the general trend. Of the 34 great zoological societies in the world, 13 concern themselves with zoology in general (40,178 members), the others are specialist: 10 societies of entomology, with 10,165 members, 7 of ornithology, 10,672, 2 of mammalogy, 1775, one of ichthyology, 650, and one of ecology, 600.

THE distribution of the zoological societies gives a glimpse of the Nature-loving character of nations. The United States possesses 12 zoological societies (15,299), Great Britain 7 (19,163), Germany 5 (6110), Holland 2 (7640), France 2 (2400), one each in Belgium, Canada, Hungary, Austria, Australia, and Japan, with membership varying from 10,415 in Belgium to 538 in Japan. The Belgian Société royale de Zoologie d'Anvers is the largest of zoological societies, its 10,415 members indicating perhaps the standard of the simple acquirements which admission demands, next on the list in magnitude are two well-known British institutions—the Zoological Society of London (8200) and the Royal Society for the Protection of Birds (4500). It is curious that zoological societies as things apart did not come into existence until the second quarter of the nineteenth century. Zoological Society of London, 1826, Royal Zoological Society of Ireland, 1832, Entomological Society of France, 1832, Entomological Society of London, 1833, Zoological Society of Amsterdam, 1838, and so on. Four societies of general natural science hail from the eighteenth century—the Society of Natural Sciences of Danzig, 1743, the Society of Natural Sciences of Zurich, 1746, the Linnean Society of London, 1785, and the Society of Natural History of Hanover, 1797. In all, it would appear that at least 295,617 individuals in the world have an interest, more than fleeting, in the natural sciences.

#### Leonhard Stejneger, Antiquarian and Naturalist

It is fitting that the autumn number (No 3, 1931) of *Copeia*, a journal of cold-blooded vertebrates published by the American Society of Ichthyologists and Herpetologists, should have appeared as a special tribute to Leonhard Stejneger and his work. For Stejneger is to American cold-blooded vertebrates what G. A. Boulenger is on this side of the Atlantic. Endowed with great personal charm and a willingness to share his profound knowledge, to which the writer of this note has more than once been indebted, Stejneger is a man in whom great diversity of interests and talents has been combined. As Thomas Barbour in a tribute to his friend says, "Being an antiquarian, a classicist, a rarely accomplished linguist, and a naturalist in the widest sense, he possessed a foundation on which with good health and great industry he has built a mighty structure of rarely excellent work." The anniversary number, with its many papers on reptiles, amphibians, and fishes, is a fitting monument to this native of Bergen and graduate of the University of Christiania, who since 1882 has been

associated with the Smithsonian Institution and since 1911 has been its head curator of biology.

#### Reindeer Ranching in Northern Canada

DOMESTIC reindeer were introduced into Alaska from Siberia at the end of the last century and have done so well there, according to Mr. M. A. Earle Kelly in an article in the *National Review* for February (p. 215), that the reindeer ranching industry in Alaska is expected to become more important than mining. Now, he says, the three-year trek of Canada's first herd, of 3000, is nearly at an end, as they will shortly arrive at the Mackenzie delta, there to furnish stock to be established across northern Canada in the interest of the Eskimo, hard-pressed by contact with civilisation, which has destroyed or driven away the animals on which he lived. It is hoped that he will become a reindeer rancher, and four families of the Lapps, so well known in this capacity, have already reached Kittigazuit in the Mackenzie estuary, in company with Mr. A. E. Forsild, who, with his brother, has been arranging for the purchase and transport of the herd for the Canadian Government. Reindeer have done so exceedingly well in Alaska, which is now even supplying their meat for American markets, that there should be no obstacle to similar success in the contiguous Canadian tundra, which, it is estimated, could carry 12,000,000 of them, where ordinary domestic ungulates could not live.

#### The Cigarette Habit

At a meeting of the Society for the Study of Intemperance and Drug Addiction on April 12, a paper on the cigarette habit was read by Dr. J. D. Rolleston, who dealt with its history, economics, pharmacology, and clinical aspects. Cigarette smoking appears to have originated in South America, where it was reported by travellers and missionaries in the eighteenth century, and thence to have been introduced to Spain, where it was described by Casanova in a visit to Madrid in 1767. The cigarette was afterwards introduced into France and Italy, but it was not until after the Crimean war (1856), when French and English officers acquired it from their Turkish allies, that the cigarette habit became diffused over Europe. Germany, where the cigar was more popular, was among the last European countries to adopt the cigarette, it did not become firmly established in England until the 'eighties. There has been a great increase of cigarette smoking since the War, especially among women, in all European countries and the United States. Dr. Rolleston pointed out that the cigarette differs from other preparations of tobacco in its nicotine content being lower than that of the cigar or pipe, whereas the amount of carbon monoxide in cigarette smoke is comparatively high. Furfural, which is usually absent in the smoke of the pipe and cigar and present in only very small amounts in that of the Turkish cigarette, is found in comparatively large quantities in the smoke of the cheaper kinds of Virginia cigarettes and is liable to give rise to symptoms of intoxication. Medical opinion is still divided as to the part played by tobacco in general and the cigarette in particular in the causation of

certain diseases, such as angina pectoris and cancer in various situations, and the risk of laryngeal involvement in smoking by tuberculous patients. General unanimity, however, seems to prevail as to the injurious effects of smoking by the young or by the subjects of cardiac neurosis or peptic ulcer.

#### Food Preservation by Refrigeration

THE publication, by the Australian Council for Scientific and Industrial Research, of a survey and scheme for research in refrigeration as applied to the preservation and transport of foodstuffs is a matter of importance at a time when attention is being focused on means of improving and extending export trade. The report has been prepared by Dr J R Vickery, who is in charge of the newly created Section of Food Preservation. Information is particularly required as to the possibility of exporting beef in a chilled rather than frozen condition, and since there appears a considerable outlet in Great Britain for Australian bacon pigs, and good ham and bacon can be manufactured from frozen carcasses, investigations are needed to determine the best methods of freezing, storing, and thawing them so that the curing process may be most successfully carried out. Fruit, particularly apples and pears, forms another large branch of Australia's export trade, but much loss is sustained annually through wastage during transport. Besides the need for more definite information as to the best type of storage conditions, knowledge is lacking as to where temperature and humidity are particularly important, and how far pre-picking factors such as orchard conditions and degree of maturity of the fruit, etc., may affect its subsequent storage life. The report concludes with recommendations for the establishment of two laboratories with attached cold storage facilities, at Brisbane and Melbourne, the former to study problems in meat export trade and in the transport of tropical fruits, and the latter to investigate the preservation and transport of non-tropical fruits.

#### Estimation of Food in a Bird's Stomach

THREE methods have been employed in estimating the quantity of food in a bird's stomach, in order to discover whether a bird is beneficial or harmful: the materials found may be weighed, they may be measured by volume, they may be counted. The weighing method is not practicable, because quantities are sometimes exceedingly small, and besides, relative weights of vegetable and insect matter convey no real information about the economic status of the bird. The second method, of estimating by volume beneficial insects and injurious insects, useful vegetation and useless vegetation, has been almost universally adopted, following the practice of the experts in the Bureau of the Biological Survey of the United States Department of Agriculture. A reaction from this method is noticeable in a monograph on the food-habits of the Californian brewer and red-winged blackbirds by Pablo S Soriano (*Califorma Fish and Game*, 1931, p 361). Here percentage by volume has been used only in estimating the space occupied by vege-

table food or animal food or pebbles in the stomach, since the presence of one limits the presence of the others. But, since the degree of injury or benefit that an animal does depends directly upon the total number of injurious organisms that it destroys, the numerical method, of actually counting the specimens, has been followed in taking the percentage of the different kinds of foods. So an old method, once universally used, but ousted by the volumetric method, returns to favour again.

#### Advancement of Science in Australasia

THE twenty-first meeting of the Australian and New Zealand Association for the Advancement of Science is to be held in Sydney, during the week commencing Aug 17. The president is Mr E C Andrews, Government Geologist, Sydney, and the president-elect Sir Hubert Murray, Lieutenant-Governor of Papua. According to the preliminary programme, the following presidents of sections have been appointed: Section A (Astronomy, Mathematics, and Physics), Prof C E Weatherburn, University, Perth; Section B (Chemistry), Prof L S Bagster, University, Brisbane; Section C (Geology), Prof H St J Summers, University, Melbourne; Section D (Zoology), Prof G E Nicholls, University, Perth; Section F (Anthropology), Mr E W P Chinnery, Government Anthropologist, Rabaul, Mandated Territory of New Guinea; Section G (Economics, Statistics, and Social Science), Mr E C Dyason, 92 Queen Street, Melbourne; Section H (Engineering and Architecture), Mr J R Kemp, Main Roads Commission, Brisbane; Section I (Medical Science and National Health), Dr R W Cilento, Director of Tropical Hygiene, Brisbane; Section K (Agriculture and Forestry), Prof J W Paterson, University, Perth; Section L (Veterinary Science), Dr W A Robertson, Director of the Division of Veterinary Hygiene, Department of Health, Canberra, F C T; Section M (Botany), Dr R S Rogers, 118 Hutt Street, Adelaide; Section N (Physiology and Experimental Biology), Dr C H Kellaway, Director of the Walter and Eliza Hall Institute, Melbourne Hospital, Melbourne; Section P (Geography and Oceanography), Dr P Marshall, Department of Scientific and Industrial Research, Wellington, New Zealand. The honorary general secretary of the Association is Dr A B Walkom, Science House, Sydney.

#### X-Ray Crystal Analysis and its Applications

THE discourse to be given by Sir William Bragg at the Royal Institution Conversazione on Friday evening, May 6, will be related to the various developments in pure and applied science which have depended on the use of the X-ray methods of analysing crystal structure. In order to supplement the discourse, which cannot refer to more than a few of the more important points, an exhibition is being arranged in the rooms of the Royal Institution which will demonstrate more fully the work that has been done. The contributors will be those who have carried on research work in this subject in various British labora-

tories, so that the result should be interesting and, so far as space allows, comprehensive. Members of scientific societies or senior students of universities and technical institutions, and others interested in this work, are invited to view the exhibits at the Royal Institution, 21 Albemarle Street, London, W 1, between 10 A M and 6 P M on Monday, May 9, or Tuesday, May 10. The Managers of the Royal Institution would be glad if such visitors would leave their names and addresses.

#### Announcements

LORD RUTHERFORD will open a discussion on "The Structure of Atomic Nuclei" at the Royal Society on April 28, at 4 30 P M. It is hoped that the following will take part: Dr J Chadwick, Dr C D Ellis, Prof R H Fowler, Prof J C McLennan, Prof F A Lindemann, and Mr N F Mott.

THE first Royal Society conversazione this year will be held in the rooms of the Society, Burlington House, on Wednesday, May 11.

At the meeting of the London Mathematical Society on Thursday, May 19, at 5 P M, at Burlington House, Prof H Levy will deliver a lecture on "A Numerical Study of Differential Equations". Members of other scientific societies who are interested are invited to attend.

SCIENCE Service announces that Dr Oscar Rice, of Harvard University, has been awarded the Langmuir prize of one thousand dollars of the American Chemical Society for work on the application of modern theories of physics to chemical problems, including the application of quantum mechanics to reactions between gases, and of modern theories of statistics to the study of metals and electro-capillarity. The award is given to a chemist in North America, man or woman, less than thirty years of age, in recognition of outstanding research in pure chemistry.

HIS MAJESTY THE KING has approved the award of the Royal Medals for 1932 of the Royal Geographical Society as follows: *Founder's Medal* to Mr H G Watkins, for his work in the arctic regions, especially as leader of the British Arctic Air Route Expedition; *Patron's Medal* to H R H the Duke of Spoleto, for his work in the Himalaya as leader of the Karakoram Expedition of 1929. The Council of the Society has made the following awards: *Victoria Medal* to Prof A P Coleman, of Toronto, for his contributions to the geography and geology of Canada; *Murchison Grant* to Dr K S Sandford, secretary of the Commission of the International Geographical Union on Pliocene and Pleistocene Terraces, for his personal work in that investigation during the past six years; *Back Grant* to Mr Hugh Clutterbuck, for his expedition to Akpatok Island; *Cuthbert Peek Grant* to Miss Gertrude Caton-Thompson, for her investigations in the historical geography of Lake Moeris; *Gill Memorial* to Dr E B Worthington, for his studies of East African Lakes.

A PRELIMINARY programme has been issued of the forty-third Congress of the Royal Sanitary Institute,

to be held at Brighton on July 9-16, under the presidency of Lord Leconfield. Among the subjects to be discussed are: prevention of measles mortality, vaccination, birth control, food and nutrition, illumination in industry, mental hygiene, aerobic and anaerobic organisms in sewage treatment, and teaching of hygiene and mothercraft in schools. Prof C E A Winslow, professor of public health at Yale University, will deliver the lecture to the Congress, and he will take as his subject "Current Tendencies in American Public Health". A Health Exhibition has been arranged in connexion with the Congress in the Dome and Corn Exchange. The Town Clerk and the Medical Officer of Health of Brighton are acting as the honorary local secretaries.

In connexion with the tours in the U S S R referred to in NATURE of April 2, p 503, it has been found that certain of them will clash with meetings of the British Medical Association and the International Physiological Congress at Rome. An additional tour has therefore been organised to leave London on June 18, returning about July 12. This party, however, can only be arranged if sufficient definite applications are received not later than May 20.

MESSRS Dulau and Co, Ltd, 32 Old Bond Street, W 1, have just issued a catalogue (No 198) of some 600 second-hand works at popular prices, dealing with the subjects of botany, entomology, ornithology, and general zoology.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A full-time woman assistant pathologist at the Elizabeth Garrett Anderson Hospital, Euston Road—The Secretary, Elizabeth Garrett Anderson Hospital, 144 Euston Road, N W 1 (April 28). A full-time lecturer in mechanical engineering at the Heanor Mining and Technical Institute—The Director of Education, County Education Office, St Mary's Gate, Derby (April 30). Two Imperial Chemical Industries' scholars at the Constantine Technical College, Middlesbrough—The Director of Education, Education Offices, Middlesbrough (April 30). A lecturer in geography at University College, Rangoon—The Secretary, Universities Bureau of the British Empire, 88A Gower Street, W C 1 (April 30). An assistant lecturer in agricultural economics in the University of Leeds—The Registrar, University, Leeds (May 2). An assistant lecturer in chemistry (with subsidiary botany, or pharmacognosy, or pharmacy) at the Belfast Municipal College of Technology—The Principal, Municipal College of Technology, Belfast (May 3). An assistant lecturer in chemistry at the Liverpool Central Municipal Technical School—The Director of Education, Education Offices, 14 Sir Thomas Street, Liverpool (May 6). A woman principal of the Bingley Training College for Women—The Education Officer, County Hall, Wakefield, Yorks (May 9). A woman principal of the Municipal Training College for Women Teachers, Portsmouth—The Secretary for Higher Education, Municipal College, Portsmouth.

### Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

#### Light and Diet as Factors in Relation to Sexual Periodicity

IN his recent communication regarding light as a factor in causing sexual periodicity in birds and mammals, Dr F H A Marshall<sup>1</sup> has directed attention to several examples of the induction of sexual activity in birds by prolonged daily light periods, and to the great rarity of animals not exposed to light variations at some time. Even nocturnal animals are subject to twilight. Not all have the same degree of susceptibility to light in this respect. He also cited conditions in tropical regions, such as the Cameroons, "where environmental conditions are similar throughout the year" and "native birds have no restricted breeding season but breed at any time."

That this is true only in a very broad sense was shown by Bates,<sup>2</sup> who found that some native birds breed there at any time, others only in the dry seasons, twice a year (in May, June, and July, and in November, December, and January), others only through half the year. Sex glands of both sexes often remain in breeding condition and size throughout the year. This suggests that breeding may be controlled by some factor other than light periods in some or all of these birds, even though comparatively long light periods may keep the sex glands actively producing germ cells.

Moreau<sup>3</sup> pointed out that, in any district, each species of bird has a rather restricted breeding season of about three months, relatively constant for any locality, but differing in neighbouring localities. He also pointed out that length of day is constant throughout the year only on the equator. It varies 40 min at 6° N or S, 70 min at 10°, and 3 hr at 23 5°. In this respect, therefore, the transition from equator to poles is gradual throughout, and differences are those of degree only. Light, in its relation to sexual periodism, is a world problem.

Moreau accepts Rowan's hypothesis<sup>4</sup> that longer periods of wakefulness or exercise induce sexual activity in many species in addition to juncos and crows, but finds it of doubtful value in the cases of long migrants, wintering beyond the equator, or on both sides of it. He is of the opinion that food is a controlling factor in breeding periodicity of tropical birds, the breeding seasons of which are seldom longer than three months. At Amari and Zanzibar, these seasons differ for species common to both districts. So the sexual activities of tropical birds are subject to seasonal cycles comparable with those of palæ-arctic birds. For him, this rules out photoperiodism for these birds, and makes climate and food supply more dominant factors in their sexual cycles. Lynes,<sup>5</sup> Vaughn,<sup>6</sup> Paget-Wilkes,<sup>7</sup> and others agree, and even suggest that rains and bush fires are related to the breeding cycles in Nyasaland.

Recent work by Bissonnette,<sup>8</sup> and Bissonnette and Wadlund,<sup>9</sup> on the modification of the sexual cycle of starlings in America, shows that testis activity is conditioned by daily period, intensity, and wave-length of light. The long wave red rays stimulate, and the shorter wave green rays inhibit germ cell activity. But, no matter how stimulating the light ration used, sexual regression sets in after a variable period of complete sperm formation. This period is

shorter in animals brought to the climax quickly, and longer in those activated more slowly. An optimum wave-length, somewhere in the red, and an optimum intensity of light, below 1856 foot candles of white light and nearer 29 foot candles intensity, are indicated. These results with starlings were obtained when birds were fed on a varied diet, rich in proteins, fats, and vitamins.

On the other hand, some unreported recent studies with starlings in Cambridge, using red light of a potency capable of inducing complete sperm formation in about twenty days on the rich diet used previously, indicate that, on a diet restricted to 'middlings' gram mash, the very stimulating red light is prevented from inducing testis activity, even in 22 days. This shows that, even when the daily light ration is adequate to induce sexual activity, the type of food may be a limiting factor and, under such conditions, control the appearance of seasonal activity. This may be the case with tropical birds, as described by Bates, Moreau, and others, and may account for the apparent correlation of diet with reproductive periodicity. Then, too, light intensity varies as between rainy and dry seasons.

Variations of susceptibility, of members of the same or of different species, to changes in light rations, would cause breeding activity to occur at somewhat different dates, even in the same locality, whether species are permanent residents or migrants.

In studies of mammals in this relation, by Bissonnette,<sup>10</sup> Baker and Ranson,<sup>11</sup> Marrian and Parkes,<sup>12</sup> and Moore and Samuels,<sup>13</sup> light ration and food have been found to influence reproductive activity. When either one of these two factors remains constant and adequate for activity, the resulting activity may be varied by changes in the other factor.

It becomes more evident that, while light ration plays a great part in conditioning the periodicity of sexual cycles in many birds and mammals, it is not the only factor operating. Seasonal changes in type or quantity of food must be reckoned with, in analysing the factors effective in any particular case.

We are still far from a general law in this connexion. But all will agree with Dr Marshall in maintaining the wide application of this principle of photoperiodism in sexual cycles.

#### Albertus Magnus as Chemist

THE article by Dr Greenwood<sup>1</sup> seems to me to lay too little stress on the point that while Albertus Magnus certainly advanced botanical and zoological science by much valuable original observation, yet in the realm of chemistry he contented himself with repetition and interpretation of earlier writings. The opposite impression given by the article seems to be due to the fact that Dr Greenwood regards "De Alchimia" as authentic. This book is, of course,

included in Jammy's collected edition of Albertus's works (an edition which is unfortunately not critical and often scientifically incomprehensible by reason of numerous textual mistakes), and in the still worse reprint of this edition by Borgnet. However, all Albertus's critics, from his first biographer, Petrus de Prussia, to Quétif, Sighart, and de Loe, down to Pangerl, have all definitely stated that he is not the author of this work, which completely cuts out all that has been repeatedly said about Albertus's personal experimental work.

In the genuine "De Mineralibus" Albertus does indeed refer to the composition of metals and to alchemistic questions, but only from a literary point of view, closely following Arabian writers, and he mentions occasional observations but never any personal tests really worthy of the name of chemical experiments. The phrase from "De Mineralibus", quoted by Dr Greenwood, "I have tested alchemistic gold", is not quite exactly translated thus, in the original it runs "*experiri feci, quod aurum alchimicum, quod ad me devenit, postquam 6 vel 7 ignes sustinuit, statim amplius ignitum consumitur et perditur, et ad faecem quasi revertitur*" (my italics). He himself had, therefore, not even made the very simple experiment of testing gold by fire, but had *had* it done.

That in the expression "*experiri feci*" the word "*experiri*" means "make an experiment", can be proved by Albertus's usual mode of speech. Compare, for example, the phrase "*Hi autem qui in cupro multum operantur in nostris partibus, Parisus videlicet et Coloniae et in aliis locis, in quibus fui et *vidi experiri*, convertunt cuprum in aurichalcum per pulverem lapidis qui calamina vocatur*" ("De Mineralibus", 11, 2, 6). Here there can be no doubt regarding the meaning of the word "*experiri*", so that the actual significance of "*experiri feci*" as "I have had experiments performed" becomes clear. When, on the other hand, Albertus has himself made experiments or observations he uses the normal "*expertus sum*", for example, "*Talpa . vermibus pascitur, et expertus sum quod libenter pascitur bufonibus et ranis*" ("De Animalibus", 22, 143). Therefore the phrase quoted by Dr Greenwood is in itself the best proof that Albertus was *not* an experimental chemist.

Perhaps it would not be superfluous here to add that in British and American literature about Albertus—for example, in the well-known works of L. Thorndike and E. J. Holmyard—"De Alchimia" is always referred to respectfully, obviously on account of its inclusion in the collected edition, in spite of its rejection by all competent scholars—though few go so far as Dr Greenwood, who does not even mention any doubt as to its authenticity. It should be specially emphasised here that the one feeble claim hitherto made for the genuineness of "De Alchimia" has recently been quashed. In one of the earliest inventories of Albertus's authentic works, the so-called "Stams Catalogue", a book "De Alchimia" is actually listed. It can now, however, be shown, in agreement with Petrus de Prussia and the conjectures of Pangerl, that the writing thereby meant was none other than a part of the book "De Mineralibus", which had originally appeared separately, this section is by chance still preserved in a collective manuscript, in the middle of medical writings, as an independent "*tractatus de metallis et alchimia*"<sup>2</sup> (It is known of several other of Albertus's writings that parts of them appear in other manuscripts as independent books under their own titles). Neither from its style nor contents can the much-later work "De Alchimia", included by Jammy and Borgnet in the collected edition, be ascribed to him, this was clearly recog-

nised and affirmed by Hermann Kopp, in his studies of the history of chemistry, as well as by all expert Albertus scholars. In consequence, therefore, of the spuriousness of this book "De Alchimia", much that Dr Greenwood quotes as Albertus's chemical knowledge must also be struck out, only the much smaller amount to be found in "De Mineralibus" can serve as a measure of it.

Albertus apparently never experimented chemically. As head of the German Dominican Order, having to inspect all its monasteries (then including those in Holland, Hungary, and Poland), and for a while as crusade-preacher, most of his life was spent in wandering on foot (according to the rules of his Order), he had therefore ample opportunities for making botanical and zoological observations, but not for chemical experiments. It is incompatible to think of this Nature-loving yet scholarly monk spending long attentive hours with crucible and furnace in a laboratory. Even the numerous thick quarto volumes (always quoted by his admirers as evidence of his scientific eminence, whereas their very prolixity—as now preserved, at least—actually diminishes their scientific value) could be cited as still further proof that all his spare time must have been very fully occupied in writing in his study, as his biographers tell us.

Besides the critically revised editions of Albertus's botanical and zoological works, which we owe to the labours of Ernst H. F. Meyer, O. Jessen, and H. Stadler, a further scholarly edition of "De Mineralibus" is much to be desired, free from the sense-destroying faults of the collected editions, which were edited by scientifically-illiterate people. The verdict upon Albertus would not, however, be thereby materially altered. In biological science he was an original worker of a high order, but, on the other hand, in chemistry a mere speculative philosopher, wholly dependent on the Arabs.

### Electrochemical Periodicities

In the course of experiments on the anodic polarisation of platinum electrodes in dilute sulphuric acid solutions saturated with hydrogen, we have observed, at small current densities, some striking periodicities

FIG 1—Change of potential with time,  $c = 50 \times 10^{-7}$

The change of potential difference with time in a typical experiment is shown in Fig 1. In this case the electrode potential falls continuously with a marked break at  $E_H = +0.4$  volt, to about  $+1.0$  volt, and then begins to rise slowly. At  $+0.9$  volt it suddenly jumps back to its initial value. This process appears to repeat itself indefinitely. In one experiment, with a current density of  $62 \times 10^{-7}$  amp/cm<sup>2</sup>,

we observed eighteen such periodicities in about 18,000 seconds, and the phenomenon showed no signs of coming to an end. With greater current densities the return to the initial value, which is near the reversible hydrogen potential, takes place at about +0.5 volt, and only a limited number of periodicities is observed. Fig. 2 (IV) is an example, obtained with a current density of  $150 \times 10^{-7}$  amp/cm<sup>2</sup>. The number of peaks is indefinite and varies from experiment to experiment. At high current densities no periodicities

Fig. 2—Change of potential with time,  $c = 150 \times 10^{-7}$

are observed, but we have photographic records showing small peaks with a period of 0.2 sec using a current density of  $3500 \times 10^{-7}$  amp/cm<sup>2</sup>.

It is significant that these periodicities are never observed during the first anodic polarisation of the electrode. This is illustrated by curves I, II, and III (Fig. 2). After the first anodic polarisation (I) the current is stopped when the potential has reached about +1.2 volt, and the potential rises to its original value without the passage of any current. On subsequent anodic polarisations, curves II and III were obtained. In these experiments the electrode was given a constant amount of cathodic polarisation prior to each anodic polarisation. We found later that this was not essential, and that the condition necessary for the appearance of the periodicities could be produced by anodic polarisations alone.

In these experiments, potentials at which oxygen can be liberated are never reached, since the reversible oxygen potential is +1.2 volt and a considerable over-voltage is necessary even with a minute current density.<sup>1</sup> The transfer of electricity across the electrode boundary must therefore occur by some process other than the discharge of negative ions. The only substance which can give electrons to the electrode under these conditions thus appears to be hydrogen. The final stage ionisation potential of molecular hydrogen is about 15 volts, and, according to Dr R. W. Gurney's<sup>2</sup> application of quantum mechanics to electrolysis, it is not possible for hydrogen molecules in the solution to give electrons to the metal from a distance. It is thus probable that the electrons passing into the metal are derived from adsorbed hydrogen. It is suggested tentatively that the mechanism of the periodicities is as follows: at about +0.4 volt the first stage ionisation of adsorbed hydrogen molecules occurs, according to the equation

Since the dissociation energy of the  $\text{H}_2^+$  ion (in the gaseous state) is only 2.6 electron-volts and the hydration energy of  $\text{H}^+$  is of the order of 8 e-volts, it is probable that in contact with the solution  $\text{H}_2^+$  is unstable and dissociates, the hydrogen ion becoming

hydrated and the hydrogen atom passing into the electrode. There are now two processes whereby the transfer of electricity from the solution may occur, namely, by (1) and by the process

It is suggested that, for some reason which is at present obscure but may possibly be connected with the mechanism of diffusion of hydrogen atoms into platinum, the rate of process (2) may suddenly increase to a value greater than that necessary for the passage of the constant current. The potential difference will then rise, until the rate of (2) is adjusted to the current passing. The subsequent slow fall marks the gradual depletion of hydrogen in the metal. Ultimately potentials are reached at which process (1) occurs and the sequence begins again.

We are examining the phenomenon in detail in the light of this hypothesis, and we intend to find if similar effects can be obtained with other metals.

#### Water-jet affected by Tobacco Smoke

A HOLLOW spindle-shaped water-jet (Fig. 1, A) may be produced by discharging the water through a cylindrical nozzle attached centrally to the bottom of a cylindrical vessel, in which the water is made to revolve by attaching a pair of inlet tubes tangentially to the top of the vessel. When a plate is placed horizontally at a proper distance below the nozzle and the rate of discharge suitably adjusted, a conical jet

FIG. 1

(Fig. 1, B) is formed, which tends to contract in diameter, if left undisturbed. The contracting cone expands and resumes its original size if it is disturbed and broken by any obstacle. If, again, a thin glass tube be inserted through the skirt of the cone and air be blown into the cone, the jet-cone becomes expanded, especially near its lower margin, such that the jet assumes a form like a trumpet. If a puff of tobacco smoke is blown gently towards the jet, the cone, previously assuming a form as in Fig. 1, B, is expanded suddenly into the form as shown in Fig. 1, C.

The gradual contraction is due to the decrease of pressure in the inside of the cone. The effect of

smoke may be explained by the decrease of the surface tension of water

Detailed experiments were carried out by one of us (K Itô) regarding the effects of the rate of discharge, as well as the size and shape of the nozzle, upon the form of the jets, and the results will be published later in the Report of the Aeronautical Research Institute

### Upper Air Temperatures and Humidities in the Indian Peninsula

SINCE October 1928, more or less regular ascents of sounding balloons have been carried out from Poona and Hyderabad (Deccan) with meteorographs of the Dines type manufactured at the Upper Air Observatory, Agra. The ascents at Hyderabad were made from

FIG. 1—Upper air temperature over Agra, Poona, and Batavia

the Nizamiah Observatory, Hyderabad, with the kind co-operation of its director. It may be of interest to summarise here some results of outstanding importance obtained as a result of these soundings

(1) During the monsoon months, July and August, the atmosphere over the Deccan is invariably colder than that over Agra in northern India, up to a level of about 14 geodynamic kilometres—the maximum mean difference of temperature being  $7^{\circ}\text{C}$  at a level of 10 gkm. Temperatures over Batavia in these months are lower still. The level of the tropopause in this season is about the same, or slightly lower, and its temperature higher in the Deccan than in northern India (Fig. 1). Considering the troposphere as a whole, the thermal equator over Indian longitudes lies over northern India at a latitude of about  $25^{\circ}\text{N}$ .

These results are specially interesting in view of the westerly to north-westerly movement of monsoon depressions. The normal upper winds are consistent with the temperature distribution

During the months July-September, the relative humidity in the air over the Deccan generally shows a maximum (saturation) between 1.5 gkm and 3.5 gkm, and is followed by a more or less rapid fall, extending over one or two kilometres, and at still higher levels by a rise. In about half the number of available records, the humidity falls off above 6-8 km, the fall being gradual. The decrease of humidity above the lower level of maximum humidity is sharper and larger during times of weak monsoon. It may be mentioned that the westerly winds of the monsoon give place to the easterlies of the inter-tropical circulation normally between 6 km and 8 km.

(2) Conditions are markedly in contrast in the winter. In the period November-February, temperatures over northern India are lower than those over Poona up to 13 gkm, and above that level higher. Between 4 gkm and 14 gkm, there is little difference between the temperatures over Batavia and Poona, but the tropopause is higher nearer the equator, and colder.

(3) The semi-permanent anticyclone in the upper air over the central parts of India during the months November-January shows itself in the temperatures over Poona as a well-marked region of small lapse-rate extending over 0.5-1 km, and starting at a level ranging from 2.5 km to 3.5 km. The trajectories of air movement in the upper air show that the air below the inversion usually comes from the Punjab and northern Rajputana through east Central India and the Central Provinces, while above the inversion, the air supply is from a direction varying from north to west, and has, in general, a higher velocity. The air below the inversion is surface-heated continental air from higher latitudes, and has a high lapse-rate. As may be expected, there is a maximum of humidity at the top of the lower convective layer.

### Errors in Thermal Measurements

IN some recent investigations on adsorption<sup>1</sup> it seems to have been established that erroneous conclusions have been reached on account of errors unsuspected by the experimenters and arising from the time lag of thermometric apparatus. Workers with experience in thermal measurements are well aware of the possibility of such errors, and in particular the extreme care which must be exercised in the use of platinum resistance thermometers, more particularly when these are wound on insulating supports and enclosed in tubes. The application of such thermometers requires not only extreme care in avoiding thermometric forces in the circuit, but also in making certain that the very appreciable thermal lag is eliminated. Generally speaking, such thermometers are quite unsuitable for use when fairly rapid changes of temperature are involved, and in any case are best avoided, except by experienced workers. For practically all purposes, a properly chosen mercury thermometer is much more trustworthy.

Another source of error in such work, fully investigated by Prof. R. A. Millikan and by myself many years ago, is the impossibility of making any kind of cooling or heating corrections with time in the case of fine metal wire thermometers suspended in a gas in the proximity of large masses of metal or other conductors. The large interference in the temperature measurements with such apparatus, owing to radiation and conduction, cannot be eliminated by any method of extrapolation, even when a very rapid galvanometer,

such as a string galvanometer, is used. It has also been well established that the temperature coefficient of fine platinum wires is abnormal, and may vary appreciably during experiments if there is any possibility of movement of the wire, so that it is very unsafe to attempt to make temperature measurements by the use of any formula supposed to express the variation of resistance of the wire with temperature. Another apparently unsuspected source of error is involved in the use of a gas of good thermal conductivity, such as hydrogen or helium, in the calibration of apparatus in which heat transfer is involved, and the use of this apparatus for gases such as oxygen or nitrogen, the thermal conductivities of which are much less than that of the gas used in the calibration experiments.

Much greater confidence could be felt in results if experiments would bear these simple and well established facts in mind.

### Hydrogen Peroxide and the Kolbe Reaction

A "RESEARCH Item" in NATURE of March 19 (p. 442) has directed our attention to a paper by Matsuda,<sup>1</sup> in which it is shown that hydrogen peroxide is formed in the course of the anodic oxidation of acetate solutions. The amount of peroxide obtained is correlated with the simultaneous production of ethane by the Kolbe reaction. As a result of a comprehensive study of electrolytic oxidation reactions, now in progress, we have independently arrived at the conclusion that hydrogen peroxide plays a very important rôle in certain anodic processes, although our point of view concerning the origin and influence of the peroxide is fundamentally different from that of Matsuda. It is hoped very shortly to publish the results of some of the experiments on which our views are based.

### Constitution of the X-Chromosome in *Drosophila obscura*

THE recent discovery of *Px*, the allelomorph of the "Pointed" mutation in *Drosophila obscura*, m1, a sex-linked intensifier, and m2, an autosomal modifier, have enabled me to analyse the constitution and possible origin of the V-shaped X-chromosome in *Drosophila obscura*.

The great similarity in the morphological expression of Pointed in *D. obscura* and Beaded in *D. melanogaster*, and the similarity of their behaviour in the presence of modifying factors, proves their homology. The difference between the physiological effect of Pointed and Beaded, consisting in the fact that Beaded is lethal when homozygous and Pointed is not, is presumably due to their position in different genic systems.

The comparison of other corresponding genes in *D. obscura* and *D. melanogaster* such as yellow, white and eosin, shows that these genes do not exhibit their effects in the same degree in the two species, pre-

sumably because of the different genic systems in which they are placed.

If Pointed and Beaded are homologous, then we may explain their different position in the linkage groups by the translocation of the chromosome segment bearing the gene for these mutations. This assumption receives strong support from the comparative study of the chromosome complements in the related *Drosophila* species. The X-chromosome in *melanogaster*, *virilis*, and *simulans* is rod-shaped, in *obscura* and *willistoni* it is V-shaped and large as compared with the autosomes. Lancefield<sup>1</sup> (1922) and Metz<sup>2</sup> (1922) suggested that one arm of the V-shaped X-chromosome in these latter species corresponded to the rod-shaped X in *D. melanogaster*. If this is the case, it is reasonable to assume that the other arm of the V-shaped X-chromosome corresponds to a segment of one of the autosomes in the species with a rod-shaped X. This kind of condition would have been brought about by translocation, either of part of an original autosome to the X-chromosome or of a part of the X-chromosome with an autosome.

Comparative studies of the sex-linked mutations in these different species show that many identical genes, for example, the closely linked yellow-scute-white-Notch series, are transferred from the extreme left end of the X-chromosome in *D. melanogaster* to the middle region of the X-chromosome in *obscura* and *willistoni*. Recent investigations of the behaviour of Pointed and Pointed-x, located in the 'extra' arm of the V-shaped X-chromosome, indicate their homology with Beaded in the third autosome of *D. melanogaster*. It is therefore suggested that part of the X, namely, the segment to the left of the yellow locus in *D. obscura*, corresponds to part of the third chromosome of *D. melanogaster*.

Further evidence of such a chromosome rearrangement is given by the study of the hybrids of 'Race A' and 'Race B' in *D. obscura*.<sup>3</sup> (Lancefield 1930, Koller 1932) The hybrid females are partially fertile and exhibit great reduction in crossing-over at both ends of the X-chromosome, the males are sterile. I have shown<sup>3</sup> (1932) that only the ends of the X-chromosome differ in the two races (A and B) of *D. obscura*. This can be explained on the assumption that the translocated segment of the X's has a different origin in the two races, and that these non-homologous portions prevent the chromosomes from pairing and crossing-over.

These facts support the hypothesis regarding the constitution of the X-chromosome in *D. obscura*.

### Mutation in Rice

THE incidence of mutation has not been infrequently reported in the common rice plant, *Oryza sativa* L. Most of the reported mutations in this crop plant are without any agronomic merit.

Matsuura,<sup>1</sup> in his monograph on plant genetics, mentions most of the mutations reported in rice. According to him, a case of dominant dwarf mutation originating from a common recessive rice was reported by Sugimoto (1923) Akemine (1925) and Nagai (1926).

mention cases of recessive dwarf mutations. Gene mutations resulting in various kinds of sterility have also been observed. Terao (1917, 1921), Kondo and Ono (1923), and Nagai (1926) record cases of complete or partial sterile mutants in rice. Terao (1922) mentions also a case of a 'large-grain' mutant from a common race of paddy.

During the rice season of 1931, I noted in the seedling stage after transplanting the appearance of three variant plants in a paddy culture of hybrid origin. These three plants were conspicuous by their short, compact, bushy growth and brevi-foliate appearance, while the remainder were tall with characteristic morphological features of an ordinary rice plant. Both the parents of the culture are normal tall plants with long leaves, and during the last eight years that the culture has gone through, no such off-type plants were ever observed.

These three plants, believed to have originated by mutation in the preceding generation, are characterised by shortened internodes, the culms ranging from 52 cm. to 60 cm. in height, in contrast to the average of 124 cm. of normal plants. The leaves are much reduced in length, but there is no corresponding reduction in breadth, as both the new type and normals show the same range. The spikelets showed normal development, and though anthesis occurred, the anthers completely failed to burst. As a result, the panicles were entirely sterile. This indicates that the mutated gene has also fatally affected the male gametes. One of the mutant plants was crossed with pollen from a normal plant from the same culture, and some seeds have been obtained. Apparently, the female gametes are functional. The inheritance of this abnormality is under investigation.

#### Fatuoids or False Wild Oats

In a study of the segregates of a cross made between the tetraploid species *Avena barbata* and the diploid species *A. brevis*, certain points of interest have emerged concerning the behaviour of the characters which in the hexaploid species *Avena sativa* constitute the fatuoid complex. In the latter species, when a fatuoid is crossed with normal or cultivated type of grain the fatuoid complex behaves as a partial recessive and in inheritance gives simple Mendelian segregation, there is no break-up of the complex, and no crossing-over takes place. In the *Avena barbata*-*Avena brevis* cross, however, these same associated characters, of articulation, basal pubescence, and awn, behave in the  $F_1$  as partial dominants, particularly so in respect of the character of the articulation of the grain. Moreover, in the later generations there is a break-up of the fatuoid complex, and cross-over types are produced. Segregates have appeared in this cross in which the basal articulation and basal pubescence characters of the *A. barbata* parent occur in association with the awn and grain-apex of *A. brevis* type, and conversely segregates with typical *A. barbata* awns and the glabrous and normal or solidified base of *A. brevis*.

Chromosome counts in the root-tips of some of these cross-over types taken from the  $F_3$  generation made by Dr B L Sethi\* have shown them to be of diploid chromosome constitution.

The occurrence of crossing-over in the progeny of

this tetraploid-diploid cross is regarded as being highly important from the point of view of its bearing upon the chromosome constitution of fatuoids in hexaploid oats, and consequently upon theories relating to the origin of fatuoids in oats.

On the theory of the origin of fatuoids by 'chromosome aberration' as advanced by Huskins,<sup>1</sup> the chromosome constitution of the di-triploid group concerned with the fatuoid phenomenon is represented by the formulæ  $\frac{ABC}{ABC}$ ,  $\frac{ABC}{ABB}$ , and  $\frac{ABB}{ABB}$  for homozygous normal, heterozygous fatuoid, and homozygous fatuoid respectively (where *B* represents the chromosome bearing the fatuoid or *fatua* factors and *C* the chromosome bearing the factor or factors for normal or cultivated type of grain). On analogy with the *A. barbata*-*A. brevis* cross, if a chromosome bearing *fatua* or fatuoid factors pairs with a chromosome bearing a factor or factors for normal or cultivated grain, that is, if *B* pairs with *C*, as in the heterozygous fatuoid formula above, crossing-over should occur. Much fatuoid segregating material has been studied by different investigators, but so far no cross-over types have been recorded.

On the other hand, on the basis of the theory of the origin of fatuoids by mutation, as put forward by Jones,<sup>2</sup> and supported by Nishiyama,<sup>3</sup> in which the di-triploid group is represented by the formulæ  $\frac{ABC}{ABC}$ ,  $\frac{ABC}{ABC_1}$ , and  $\frac{ABC_1}{ABC_1}$  for homozygous normal, heterozygous fatuoid, and homozygous fatuoid respectively ( $C_1$  representing a mutational change in the *C* chromosome), no cross-over types are theoretically expected, and, as already stated, none so far have been found.

It appears to me, therefore, that the occurrence of crossing-over in the tetraploid-diploid cross (*Avena barbata*-*A. brevis*) gives further support to the hypothesis that fatuoids in hexaploid oats arise by mutation rather than by chromosome aberration.

#### Molecular Dissociation by Electron Impact

ABOUT two years ago I noticed<sup>1</sup> that the positive ions generated along the path of an electron beam nearly all came out of the electron beam at right angles to it with energies of the order of 1 or 2 volts, that is, considerably higher than their thermal energies. I found that this was due to a radial potential gradient being set up around the electron beam by concentration gradients in the electron gas surrounding the beam. The presence of these radial potential gradients would introduce considerable difficulties into the accurate measurement of the kinetic energies of the dissociation products formed by electron impact in a molecular gas, for the dissociation products possess energies of only the same order of magnitude as the energy gained in falling through the potential gradient set up by the electron beam.

In a recent investigation by Tate and Lozier<sup>2</sup> of the energies of the dissociation products of nitrogen and carbon monoxide formed by electron impact, no account has been taken of the possible existence of these radial potential gradients. It is not possible to determine from my work the value of the potential gradient in Tate and Lozier's investigation, for they worked at lower pressures, and the effect of pressure on the value of the potential gradient has not been

\* Formerly post-graduate student at the University College of Wales, Aberystwyth

investigated. There is, however, little doubt that such a radial potential gradient existed in their work, for it would account for the fact, mentioned on p. 261 of their paper, that  $N_2^+$  ions were able to reach the collector, whereas they should not have been able to do so if they possessed only their thermal energies.

Tate and Lozier find for carbon monoxide the following two processes

If the energy given to the molecule by the impact is  $V_i$  and the kinetic energy with which the atoms separate on dissociation is  $V_f$ , then  $V_i - V_f$  (which is equal to  $U_2 - U_1$  in Tate and Lozier's notation) should be less for the second process by the electron affinity of oxygen. Tate and Lozier find that it is greater, and suggest that this may be due to excitation of the products of dissociation, but point out that no excitation level of the correct energy is known. For process (1) they find  $V_i - V_f = 20.5$  volts, and for process (2)  $V_i - V_f = 22.2$  volts.

Since the ions collected are oppositely charged in (1) and (2), it is clear that a small radial potential gradient around the beam would decrease the experimental value of  $V_i - V_f$  for process (1) and increase it for process (2). If we assume a radial potential gradient of 1.2 volts to exist, we find for the corrected values

$$V_i - V_f = 20.5 + \frac{7}{4} \cdot 1.2 = 22.6 \text{ volts for (1)}$$

$$V_i - V_f = 22.2 - \frac{7}{3} \cdot 1.2 = 19.4 \text{ volts for (2)}$$

giving an electron affinity for oxygen of 3.2 volts.

From another dissociation process which they detected, namely,  $\text{CO} \rightarrow \text{C} + \text{O}^-$ , Tate and Lozier deduce an electron affinity for oxygen of zero (or 0.5 volt, assuming, as they do, an experimental error of 0.5 volt) if the products of dissociation are unexcited. If we again assume a radial potential gradient of 1.2 volts, the electron affinity for oxygen deduced from this dissociation process comes out at 4.9 volts. Values for the electron affinity of oxygen quoted by other investigators range from 3.2 volts to 8.9 volts.

Besides giving a reasonable value for the electron affinity of oxygen, the assumption of a small radial potential gradient of 1.2 volts gives better agreement between the heats of dissociation calculated from Tate and Lozier's results and the spectroscopic values given by Birge and Sponer. The heat of dissociation of the normal carbon monoxide molecule is raised from 9.3 volts to 11.4 volts, and the heat of dissociation of the ionised molecule is raised from 6.4 volts to 8.5 volts. The values given by Birge and Sponer are respectively 10.3 volts and 9.8 volts.

#### Intensity Ratio of Fluorescent X-Ray Lines

HEVESY and Alexander have recently<sup>1</sup> published some very interesting figures on the variation of the relative intensities of the  $L\beta_2$  and  $L\beta_3$  lines of silver under fluorescent excitation by primary X-radiations of varying frequency.  $L\beta_2$  is  $L_{III} \rightarrow N_V$  and  $L\beta_3$  is  $L_{II} \rightarrow M_{III}$ . The reported change in the intensity ratio is from 100:25 at 2.6 Å to 100:60 at 1.3 Å.

This change is, as the authors point out, in the same direction as that previously noted by Skinner, and in the direction indicated by my work on X-ray electrons. I have, unfortunately, no data which are directly

applicable to this particular case, but from earlier published work and from more recent unpublished experiments I have been able to construct a rough curve which allows a rather hazardous extrapolation to be made to the region covered by Hevesy and Alexander's work. From this curve I should expect the intensity ratio of  $L\beta_2$  to  $L\beta_3$  to change by not more than about 30-40 per cent between 1.3 and 2.6 Å — very appreciably less than the 140 per cent reported by Hevesy and Alexander.

I am surprised that the discrepancy should be so large. Hevesy and Alexander's measurements are more direct and, I should imagine, more exact than mine in this particular respect, and I shall be interested to see the detailed account of their work. I hope that I may shortly be able to extend the measurements further in this direction by the photoelectric method, and possibly get some clue to the reason for this discrepancy between the two results. Some degree of extrapolation is inevitable, for technical reasons, in the photoelectric method, but I may say that my extrapolated curve agrees as well as can be expected with Kellstrom's measurements of the silver  $L$  absorption discontinuities.<sup>2</sup>

#### The Highest Oxide of Rhenium

IN the course of an investigation of the oxides of rhenium in progress in these laboratories, we have sought to repeat the preparation of the highest oxide described by I and W. Noddack,<sup>1</sup>  $\text{Re}_2\text{O}_9$ , which was obtained by them on heating the heptoxide below 150° in a stream of oxygen. The yellow heptoxide used in the Noddacks' preparations melted at 220° and gave rise to a white sublimate at 150° described as  $\text{Re}_2\text{O}_9$  and possessing the property of decolorising acidified potassium permanganate. The melting point of our specimens of heptoxide has invariably been about 300°, and this material failed to give any evidence of a white sublimate when heated in a stream of oxygen to temperatures below its melting point. Moreover, quantitative experiments repeatedly showed that its formation was unattended by any increase in weight. The sublimate was identical in crystalline form with the heptoxide, was decidedly yellow, and melted to a yellow solid, also indistinguishable from the heptoxide.

It has been known to us for some time that the melting point of the heptoxide is depressed by traces of moisture, and a specimen the melting point of which had thus been lowered approximately to 150° was found to give a white sublimate of the non-crystalline form illustrated in the Noddacks' paper, though there was no gain in weight through the conversion. In no case did any of the sublimates when carried in an oxygen stream into dilute permanganate show the slightest decolorising effect, and we are compelled to the conclusion that, in the absence of further evidence, the heptoxide must be regarded as the highest oxide of rhenium stable under ordinary conditions. A full account of this work will be published elsewhere.

## Research Items

**A Choctaw Account of the Flood**—The Smithsonian Institution has issued a summary of a report to be published in due course by Dr J R Swanston on an investigation of the culture and legends of the Choctaw Indians, which includes an account of the Flood—a tradition which the Choctaw shared with other south-western Indians. It gives an account of the destruction of mankind by the waters because of their wickedness. The form of the tradition as given here preceded the advent of the white missionaries. Later versions were modified to conform with the account in Genesis. A divinely pre-warned prophet went from village to village, proclaiming the coming of the flood, but no one heeded. Darkness, cold, and thunder came and the food of the Indians became mouldy and unfit to eat. Wild animals from the forest gathered around the camp-fires. Great waters rushed over the land from the north and destroyed everything. The prophet alone was saved. He made a raft of sassafras logs, upon which he floated for many weeks. A black bird circled over his raft, but when the prophet asked for help, it sailed away. Then a blue bird with red eyes guided him to an island in the direction of sunrise. The prophet landed and lay down in the mud to sleep. When he awoke, he found the island covered with all kinds of animals. Among them were the black bird and the blue bird. The black bird became the raven, a bird of ill-omen ever afterwards, but the blue bird became a beautiful woman, the mother of the new race of men. The Choctaw believe in a 'Great Spirit', which is closely associated with the sun, but can assume human form. Every man has two souls, of which one, identical with the shadow, is left behind after death and wanders about its former abode howling, while the other, "the inside shadow", goes to Paradise, an Elysium on earth of eternal springtime and perpetual youth, reached by crossing a yawning chasm by a slippery log.

**Influence of Pituitary on the Ovaries**—It is now well known that one or more hormones from the anterior lobe of the pituitary gland regulate the functions of the ovaries in mammals. The evidence has been obtained almost entirely by transplantation or injection of extracts of the gland, since operative removal in mammals is difficult. L. Hogben, E. Charles, and D. Slome have now supplemented the previous evidence by showing that, in *Xenopus laevis*, removal of the pituitary gland or of the anterior lobe alone produces involution of the ovaries, as well as a lowering of the serum calcium and cessation of skin secretion (*J. Exp. Biol.*, 8, 345, 1931). *Xenopus* was chosen for the experiments since it survives hypophysectomy for a prolonged period. After the complete operation the animals remain pale on a black background, the melanophores being permanently contracted, after removal of the anterior lobe alone, however, the animals remain dark even when subjected to conditions which would otherwise produce pallor. The involution of the ovaries occurs after either operation, but is more marked after removal of the anterior lobe alone. Conversely, it was found that ovulation could be induced midway between breeding seasons by injections of extracts or by implantation of the anterior lobe also, injection of extracts, especially of the posterior lobe, induces a copious secretion of slime from the skin after a few minutes. Hence it may be concluded that the anterior lobe of the pituitary has a functional influence on the ovaries throughout the vertebrate series.

**Immunology in Reptiles**—The immunological reactions of certain reptiles have recently been investigated by E. Crasset and A. Zoutendyk (*Publ. South African Institute for Medical Research*, vol. 4, p. 377, 1931). The results indicated quantitative rather than qualitative differences from the responses of mammals, and different species of reptiles showed very varying degrees of susceptibility. Thus lizards and chameleons are, in general, the most susceptible to tetanus toxin, and may be killed by a dose almost equal to that which kills guinea-pigs, although the incubation period is much longer. One species of lizard, the leguaan, however, was quite resistant to both tetanus and diphtheria toxins. Crocodiles, snakes, and tortoises show increasing degrees of resistance to tetanus toxin, but crocodiles and tortoises are as susceptible to diphtheria toxin as mammals, the lizards, and especially the snakes, being resistant. Reptiles are usually resistant to dysentery and typhoid. Intoxication is the more readily produced the higher the temperature to which they are exposed. Although differences in susceptibility to different toxins are common among mammals, the processes involved in the immunity reactions appear to be different in mammals and reptiles. Reptiles show a very low and extremely slow response to the introduction of antigen, whether they are susceptible or resistant to the toxin. The sensitivity of the cells for toxin does not have as its corollary an aptitude for the production of antibodies. Hence immunity appears to follow the evolution and specialisation of the animal species, which result in a higher differentiation and sensitivity of the specialised cells. These, so far as immunity phenomena are concerned, are characterised by a higher and more rapid aptitude of response, which has as its object the protection of the organism.

**Nephridiostome of the Earthworm**—Prof. E. S. Goodrich (*Quart. J. Microsc. Sci.*, vol. 75, pt. 1, 1931) has critically re-examined the structure and development of the funnel or nephridiostome of *Lumbricus*. He gives a detailed description of the upper and lower lips of the funnel and of the relations and structure of the canal-, gutter-, central, and marginal cells. The account of the development of the funnel is traced from the time when the nephridium consists of a post-septal string of cells reaching obliquely backwards from the septum to the epidermis and ending anteriorly in a large funnel-cell bulging forwards through the coelomic epithelium of the septum into the next segment. The whole nephridiostome (excluding the covering of coelomic epithelium and the connective tissue) is shown to arise from the nephridial rudiment, wholly or partly from that part of the funnel-rudiment which is derived from the funnel-cell. Upper, lateral, and lower lips are all developed from the funnel rudiment, in which the lumen, appearing first as a notch between upper and lower lips, becomes pierced. There is no evidence that the coelomic epithelium contributes any part of the nephridiostome. The view sometimes put forward that the excretory organ of *Lumbricus* is a nephromixium such as is present in some families of Polychaeta is not founded on sound evidence. A. Meyer, who gave an account (1929) of the development of the funnel in *Tubifex*, concluded that the nephridioblast from which the whole nephridium developed was situated on the anterior surface of the septum among the cells of the coelomic epithelium and was derived from this epithelium. Prof. Goodrich, who has seen Meyer's preparations, is convinced that Meyer is mistaken and

that he failed to trace the origin of the nephridioblast, and he adds "There seems to be no justification for Meyer's extraordinary theories concerning the general morphology of nephridia and genital ducts in the Annelida."

**Inhibition of Potato Sprouting by Ripe Apples**—A novel and simple means of preventing potatoes from sprouting even up to so late as June, was recently described by Dr O H Elmer of the Kansas Agricultural Experimental Station, in a *Science Service Bulletin*. Tests have shown that if ripe apples are stored with potatoes in a well-closed bin, sprouting is prevented, the tubers remaining firmer and of better quality than those stored without the apples, and in experiments with previously sprouted tubers, provided the shoots were within 'smelling distance' of the apples, their growth was checked. The nature of the substance which is responsible for this effect is not known, but it evidently occurs in ripe apples only, for neither green nor rotten fruit was able to bring about the same result. Further, the substance does not occur in the skin only, for peeled apples were equally efficacious. Apparently only apples and closely related fruits, such as pears, possess this property, for neither bananas nor oranges were found capable of exerting the same influence on the potatoes.

***Puccinia Malvacearum*, a Homothallic Rust Fungus**—The work of Craigie on the heterothallism of certain rust fungi has stimulated much research into the behaviour of other species of the Uredinales. Miss Dorothy Ashworth has adopted a very ingenious method of single-spore inoculation and has shown that the object of her study is homothallic ("*Puccinia Malvacearum* in Monosporial Culture", *Trans Brit Mycol Soc*, vol 16, parts 2 and 3, pp 177-202, Dec 1931). There appears to be an autoecious mechanism for diploidisation similar to that described for *Coprinus* by Buller and others. Three or four haploid cells are formed from the diploid sporidium shortly after its entrance into the host, and each sends out a thin vegetative mycelium which ramifies extensively in the mesophyll of the host leaf. Diploidisation of this vegetative structure is brought about by nuclear migration and by division without the formation of a septum. It takes place in numerous distinct patches, the sites of the future teleutospore sori. No fusion of cells has been observed.

**Vacuum Pump Liquids**—The search for more suitable liquids for use in diffusion pumps on the lines suggested by Mr C R Burch in these columns (*NATURE*, 122, 729) and continued by Messrs K C D Hickman and C R Sanford (Patent 329,918) has led Drs M von Brandenstein and H Klumb of the Physical Institute of the University of Berlin to devise a special form of pump for such liquids, and an account of their work has now been published (*Physik Z*, Jan 15). They conclude that it is possible with both oils and fats of low vapour pressure to produce vacua of the order  $10^{-3}$  dynes per sq cm. The Eastman Kodak Co has published a list of suitable liquids with low vapour pressure, and Prof P W Bridgman has investigated the compressibilities of a number of them in the Jefferson Physical Laboratory of Harvard University (*Proc Amer Acad Arts Sci*, vol 67). He finds that as the number of OH groups in an organic molecule increases, the compressibility decreases, that glycerine is the least compressible, and that organic liquids of other groups have compressibilities from three to five times as great.

**Supposed Spontaneous Transformation of Helium into Radiation**—Dr L H Gray and Mr G T P

Tarrant have contributed a short paper to the January number of the *Proceedings of the Cambridge Philosophical Society*, describing an attempt to detect the spontaneous transformation of helium into penetrating radiation. If this occurred it might, as Sir James Jeans has shown (*NATURE*, 127, 594, 1931), account for the existence of the extremely penetrating rays found by Regener by measurements in deep lakes. In the present experiments, an ionisation chamber containing nitrogen at a pressure of 100 atmospheres was exposed to five kilograms of helium at a mean distance of 45 cm, but instead of increasing the ionisation, presence of the helium reduced it to a slight extent, since the containers of the gas acted as additional shields protecting the chamber from the cosmic radiation and from  $\gamma$ -radiation from the walls of the room. After allowing for these effects, no ionisation remained which could be attributed to the helium. The limit of accuracy in the measurements was equivalent to a half period for the destruction of helium in this way of more than  $10^{18}$  years, or expressed alternatively in terms of the observed penetrating radiation from cosmical sources, the upper limit for the ionisation which might be produced if the whole of matter in interstellar space were helium is about two hundred times that actually produced at the surface of the earth by the penetrating radiation.

**Photographs of Fast Protons**—A pamphlet published by the Carnegie Institution of Washington (Feb 28), which deals with work done in its Department of Terrestrial Magnetism by Messrs M A Tuve, L R Hafstad, and O Dahl, contains a photograph of cloud trails of fast protons which had been produced by ordinary electric means. The full detail of this work is not described, but there are some excellent photographs of the lay-out of the apparatus and of the Tesla coil used. The proton trails given are too crowded to show their individual features, but seem to be fairly homogeneous in length, and to have an appearance not obviously to be distinguished from close sheafs of  $\alpha$ -particles, such as have been photographed by Meitner. It appears that this is the first occasion on which tracks of massive particles, as distinct from electrons, produced by other than radioactive methods, have been obtained.

**Ortho- and Para-Hydrogen**—In No 29 of the *Conférences d'actualités scientifiques et industrielles* (Paris Hermann, 1931) Prof E Darmais gives a very clear account of the theories underlying the existence of the two forms of molecular hydrogen and of the experiments which led to their detection and isolation. He points out that their existence was inferred from observations on the secondary spectrum, due to the molecule of hydrogen, the alternation in intensities in the lines of which was pointed out by Mecke in 1924. McLennan and McLeod showed in 1929 that the existence of two kinds of molecules in the liquid was indicated by the Raman spectrum, and Dennison in 1927 had inferred the same result for the gas on the basis of its specific heats, which could not be brought into line with the moment of inertia of the hydrogen molecule, found spectroscopically by Hori in the same year, without an assumption of two kinds of molecules. The isolation of the two forms by Bonhoeffer and Harteck in 1929, by making use of the catalytic effect of charcoal at low temperatures, confirmed all these results, and in particular the abnormal specific heat curve of hydrogen. Eucken and Hiller in 1929 were able to reproduce this curve from those of ortho- and para-hydrogen. The paper includes a short bibliography.

**Physico-chemical Study of Rare Earth Sulphates**—Prof B Brauner, with Dr E Švagr, has contributed

a lengthy paper to the *Collection of Czechoslovak Chemical Communications* (February 1932) on the sulphates of the rare earth metals, scandium, yttrium, lanthanum, praseodymium, neodymium, samarium, gadolinium, terbium, erbium, ytterbium, and thorium. The salts were prepared from the purest materials available and most of them have been used for atomic weight determinations by conversion into the metal oxide through ignition. The results are compared with those of Homgshmid, Štěrba-Bohm, Baxter, Urban, and other investigators, and the possible sources of error are discussed. The conclusion is reached that the classical sulphate method, which serves well for orientation in the fractionation of rare earth mixtures, is not exact enough for atomic weight determinations. One source of error which has probably not hitherto been taken into account is that the oxides, after glowing and cooling, absorb oxygen from the air and thus become heavier and give a figure for the atomic weight which is too high. Among the physico-chemical investigations carried out by the authors were determinations of the conductivities of the aqueous solutions of the normal and acid sulphates. Estimations of basicity were studied by the inversion of cane sugar and by the rates of hydrolysis of methyl acetate. Thorium sulphate,  $\text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}$ , and the acid salt,  $\text{Th}(\text{SO}_4)(\text{SO}_4\text{H})_2$ , the only thorium hydro-

gen sulphate obtained in these researches, showed anomalous behaviour compared with the other rare earth sulphates. This the authors attribute to the tetravalence of thorium.

**Corrosion Fatigue of an Aluminium Crystal**—The results of a life-test on an aluminium crystal, subjected simultaneously to an alternating shearing stress and to corrosion by tap-water, have been described by H. J. Gough and D. G. Sopwith (*Proc. Roy. Soc.* for March). It withstood in all more than 23 million cycles before fracturing, which was due to profuse cracking. Plastic deformation was observed only in the initial stages, but there was a continual growth of small surface pits, which tended to run together, and although they did not lead to failure in this case, might conceivably have done so. The main cause of failure proved to be corrosion on the site of previously formed slip bands. Due to this a large number of big cracks developed, and a multitude of smaller ones, in nearly every case parallel to the traces of the operative slip planes, and most thickly concentrated in the region of maximum resolved shear stress intensity. These were, in general, the results anticipated, and the experiments are now to be extended to an iron crystal, with the applied cycle of stress such as would not normally produce plastic deformation.

### Astronomical Topics

**Houghton's Comet**—Prof. H. E. Wood has computed the following orbit of this comet, which was telegraphed by Dr. Spencer Jones to the I. A. U. Bureau at Copenhagen:

|          |                       |
|----------|-----------------------|
| $T$      | 1932 April 20 080 U T |
| $\omega$ | $1^\circ 44'$         |
| $\Omega$ | 205 41                |
| $i$      | 75 39                 |
| $\log q$ | 0.06472               |

#### EPHEMERIS FOR 0<sup>h</sup> U T

|          | R. A.                                           | N. Decl. | $\log r$ | $\log \Delta$ |

| 9        | 12 16 52                                        | 59 37    | 0.0789   | 9.7592        |
| 13       | 12 17 12                                        | 61 48    | 0.0852   | 9.8055        |
| 17       | 12 18 24                                        | 63 20    | 0.0924   | 9.8624        |

The comet passes within some 15 million miles of the earth, and may be faintly visible to the naked eye, its northward motion is extremely rapid, owing to the high inclination. It moves nearly from pole to pole in two months. The elements bear considerable resemblance to those of comet 1849 II, which may indicate a common origin, identity is not possible, as that comet was observed for five months and its orbit was slightly hyperbolic.

**The Delporte Planet**—The planetary nature of this body is now established, and it has been given the designation 1932 EA<sub>1</sub>, pending the assignment of a permanent number later on. The orbit is a difficult one to compute, and the period is not yet known with precision. The following elements by Dr. A. C. D. Crommelin use observations up to April 11, and are probably not very far from the truth.

|          |                      |
|----------|----------------------|
| $T$      | 1932 April 4 808 U T |
| $\omega$ | $25^\circ 18' 49''$  |
| $\Omega$ | 171 8 51             |
| $i$      | 12 10 16             |
| $\phi$   | 26 38 17             |
| Period   | 2.767 years          |
| $\log q$ | 0.03617              |

The least distance from the earth's orbit is about ten million miles, which is only two-thirds of that of Eros.

Unfortunately, the discovery came too late to utilise the present approach, which is the most favourable one possible, for a parallax determination. On many nights, observations were taken at intervals of several hours, these, when corrected for the motion in the interval, indicate a horizontal parallax in the neighbourhood of 80". These parallax determinations helped in deducing the distance from the earth, and in deciding against a parabolic orbit.

It is very desirable that large instruments should follow the object as long as possible, to facilitate its recovery at the next favourable opposition, it will probably only be observable when opposition occurs fairly near perihelion.

The following ephemeris is for 0<sup>h</sup> U T

|          | R. A.                                           | N. Decl. | $\log r$ | $\log \Delta$ |

**Annual of Catania Observatory for 1932**—This annual publication gives, in addition to the usual contents of an astronomical almanac, a useful list of periodic comets, notes on the eclipses, and the planetary phenomena of the year. There is a special chapter on Eros, of which many photographs were secured at Catania both in 1900-1 and at the recent apparition. A portion of one of the latter plates is reproduced, a number of short exposures being given on the same plate, a sufficient time-interval being given to separate the images of Eros owing to its rapid southerly motion. A table shows that steady progress is being made in the publication of the zone of the astrographic catalogue undertaken by the observatory, some of the reductions are being carried out at Naples. Solar spectroscopic work is also carried out. Drawings of four of the most interesting prominences observed in 1931 are given, the dates are March 1, April 10 (two prominences), and May 24. There are also drawings of sunspot groups on Feb. 23 and March 12.

## Research in Textiles

IN a recently issued report on the work carried out in the Clothworkers' Departments, University of Leeds, under a research scheme established in 1928 by means of a grant of £3000 a year from the Worshipful Company of Clothworkers, reference is made to the value of the scheme not only in promoting a research plan, which has already a number of fundamental discoveries to its credit and holds promise of further work of outstanding scientific and technical importance, but also in providing industry with scientifically trained men. The report presents a survey of the three years' working of the scheme and is not confined to a statement on a single year. It is pointed out that the scheme has led directly to the creation of a school of textile research in Great Britain which has already attracted advanced workers from other countries. It is hoped that the recent creation of an honours degree of BSc in textiles will assist in discovering students who will devote themselves to continuous work in this field, and it is strongly urged that the research grants for fellowships or scholarships in colour chemistry should be put on a permanent basis in 1932. The importance of adequate research scholarships being available in periods of industrial depression is specially stressed.

The survey of work in textile physics stresses the value of the results obtained by the application of X-rays methods, to which frequent reference has been made in NATURE. The combined evidence of chemical and X-ray analysis has led to the conclusion that the structure and properties of common industrial fibres are based on three main fundamental principles: long, thin crystalline or pseudo-crystalline particles, with their long dimensions inclined at a constant angle to the fibre axis, as in cotton, or parallel to the fibre axis, as in ramie, silk wool, etc. If the molecular chains are inextensible the fibres can be stretched only by making the molecular bundles slip over one another, examples being cellulose fibres, natural silk, stretched wool and other animal hairs, and stretched rubber. If, as in cellulose and silk, the straight molecular state is the normal state, there is only a limited power of recovery from extension. If, however, the molecular chains are themselves extensible, as in unstretched wool, hair, and unstretched rubber, the fibres can be stretched to abnormal dimensions and afterwards recover their original length exactly.

Further investigations have shown that by various methods wool can be contracted to half its original length, while X-ray studies on the permanent set of stretched wool and hair have revealed that steam acts on the extended molecules so as to prevent their contraction to the folded state. The process is analogous to the vulcanisation of rubber, and detailed results of the 'setting' of wool by steam will shortly be published. X-ray analysis of fibres has not only supplied strong evidence in support of the chain theory of protein structure but also is now furnishing important information about the actual growth of cellulose in Nature, and X-ray photographs of the wall of *Velonia ventricosa* promise to throw light on

one of the greatest problems in botany and agriculture. X-ray photographs of the structure of feathers have also shown that feathers and tortoise-shell give a common X-ray photograph which is different from that of wool and hair, and accordingly the classification of their fibrous protein with the keratin of wool, hair, horn, etc., in most textbooks is incorrect.

On the physico-chemical side, the studies of the elastic properties of wool which have already indicated the underlying causes of the permanent setting of hair have now led to the discovery, of far-reaching importance for wool-finishing processes, that the 'set' imposed at any one temperature is permanent only to water at a lower temperature than that at which it was imposed. This and the subsequent discovery that caustic soda solutions have the same property of being able to eliminate permanent set have led to the development of two new finishing processes for producing crêpon effects.

Investigations on the relation of rigidity to the amount of moisture present in the fibre and to atmospheric humidity showed that while the breaking load of wool fibres is only reduced in the ratio 1.5 : 1 by a change from absolute dryness to saturation with water, the rigidity changes in the ratio 15 : 1, and thus afforded an explanation why artificial humidification is essential for spinning mills but relatively unimportant at other stages of manufacture. Further explanation of variations in the spinning properties of wool has been found in the discovery that the affinity of wool for water decreases as the temperature at which it is dried increases.

These investigations not only make an important contribution to the knowledge of the structure of wool but also afford explanations of important technical points, such as fastness to rubbing. Most wool dyes are smaller in particle size than the pores of the swollen wool fibre and penetrate to the interior of the fibre. Dye molecules or particles which are larger in size than the pores of the swollen fibre can only be absorbed at its external surface, and the dye is accordingly readily removed by rubbing.

Other recent work has shown that acids have the property of attacking and subdividing the micelle structure itself, rendering the fibre easier to stretch. The further discovery that wool is completely immune to attack by acid and alkali over a wide range, known as the pH stability region, not only affords a striking and independent confirmation of Svedberg's results on soluble proteins, but is also of considerable significance in relation to wool scouring. It has also been possible to establish definitely the nature of one of the linkages in the wool molecule and thus to show that the combination of wool with acids and acid dyes is a strictly chemical process. The further discovery that at high temperatures the wool micelles are subdivided by water alone has a profound significance for the acid dyeing of wool. Space does not permit further reference to numerous other more technical researches which among other points have established the importance of perfect elasticity as well as surface scale structure for milling shrinkage.

## Standardisation of Screw Threads

IN the *Human Factor* (vol 6, No 2) there is an interesting article by W F Watson, a working mechanic of thirty years' experience, describing the conflict between the duodecimal and decimal systems of measurement in his domain. He surveys the history of the two systems of measurement in the various

countries, and the gradual success of the decimal, except in England. He illustrates the trials of the turner and manufacturer, by a study of screw threads.

The first attempt at securing uniformity in screws was made by Sir Joseph Whitworth in 1841, and in the course of twenty years the Whitworth system

was the recognised standard for general engineering purposes. Prior to that, each firm had its own 'standard' set of screwing tackle, the existence of which made engineering repairs costly and inconvenient. Owing to the pre-eminent position occupied by British engineering, the establishment of a British system was very favourable, and no difficulty was experienced in securing the adoption of Whitworth screws in Germany and the United States.

The two great attacks made on the Whitworth system came from the Franklin Institute in 1864, when the Sellers thread was adopted and recommended to American engineers, and in 1873, when Delisle of Karlsruhe initiated a metric system. In 1918 the International Screw Thread Congress adopted the international metric screw thread. Now the metric system of screw threads is standardised on the continent of Europe, America has its Sellers standard, whilst Great Britain retains the Whitworth system.

It is said that the threads now recognised as standards are included in about eight great systems,

but a popular handbook gives details of no fewer than thirty different kinds of screw thread. As an example of the practical confusion arising, Mr. Watson says that if we place side by side a half-inch American screw, an English half-inch screw, and a 12 mm screw (2 mm pitch), it is not easy to note the difference. The American screw has, however, 13 threads to the inch, the English 12, and the metric 13.7, and the angles are 60°, 55°, and 47.5° respectively, therefore each must have its special nut. As in these days engineers are constantly handling the products of other countries, and as two different systems of screws may be employed on the same machine, much time is wasted in finding the standard used and in trying to get a screw conforming to that standard.

A similar difficulty is experienced in wire and sheet metal gauges. It may be suggested that the time is ripe for the various bodies concerned to examine all sides of the question, with the view of securing the adoption of an international system of measures for all commercial purposes.

### Embryology of the Slime Eels \*

THE Myxinoidea or slime eels have been the subject of inquiry and discussion by many investigators in both Europe and America. Much difference of opinion for a long time existed, and even yet remains, with regard both to the facts concerning them and to their interpretation. So little were these animals at first understood that the earliest investigators classified them with the worms. This error was early rectified, but great controversy continued to centre round such questions as whether the Myxinoids are or are not parasitic, whether they are primitive or degenerate, and whether they should be classified as Gnathostomata or Agnathostomata.

On the last question agreement had almost been reached, most morphologists and embryologists having placed them in the former group, when recently a sole investigator who has arisen in the field of myxinoid palæontology, stoutly claims for them a place in the latter. The excretory system has been described by some workers as a pronephros, by others as a pronephros which eventually becomes transformed into a mesonephros, and by still others as a small pronephros and a posterior segmental mesonephros which develops in the usual manner. The reproductive system, too, has been very extensively studied. Because of peculiarities in the structure of the generative organ, the myxinoids have long been believed to be functional hermaphrodites—in fact, they are still definitely stated to be so in even the most recent textbooks.

For many years the assistance of embryology in solving these and other problems connected with this difficult group was denied, because no one was able to find embryos developing in their natural environment or to obtain them by keeping the 'eels' in captivity. Neither did palæontology contribute towards their elucidation, for until quite recently no fossil cyclostome had been found—with the possible exception of *Palæospondylus*, supposed by some to be a Devonian lamprey. This belief, however, was firmly rejected by Dr. Bashford Dean, by whom many valuable contributions to our knowledge of the Myxinoidea were made during the time that he was professor of zoology at Columbia University.

From examination of his notebooks, it seems quite

certain that this industrious and talented investigator had intended some day to publish still further information which he had gleaned, especially on the genital system of *Bdellostoma*. It is particularly fitting, therefore, that the Bashford Dean Memorial Volume on "Archaic Fishes" should contain this section on the Myxinoidea based on the unpublished data left by Dr. Dean in the form of notes, graphs, tables, and sixteen excellent drawings. This contribution to the volume is written by Prof. Leroy Conel, who for twelve years was associated with Dr. Dean in his work.

This author, before presenting Dr. Dean's notes and data (dealing mainly with the reproductive system of *Bdellostoma*), gives a brief but very useful review of the previous literature on the subject, in which the problems which Dr. Dean set out to solve are clearly indicated. *Myxine glutinosa*, the representative of the group mainly studied by previous workers, was stated by Nansen (1887) to be a functional protandric hermaphrodite. Cunningham (1891), though disagreeing with some of Nansen's observations, came to the same conclusion. In 1899 Dr. Dean published a paper in which he expressed grave doubts as to the truth of this assumption—doubts which were later supported in the publications of A. and K. E. Schreiner (1904-8). These authors held that, though undoubtedly hermaphrodite in structure, *Myxine* is functionally dioecious.

On account of this uncertainty concerning the true state of affairs in *Myxine*, Dr. Dean, in search of further evidence, turned his attention to other members of the group, *Bdellostoma stouti* and *B. burgeri*. In these he found the gonad of each individual examined to be definitely either a testis or an ovary, and concluded that both species of *Bdellostoma*, at least, are very rarely, if ever, hermaphrodite at any stage of their life history. This finding, he contended, made it still more difficult to believe that the closely related *Myxine* is a functional hermaphrodite. In 1896, in order still more fully to investigate the life history of the Myxinoidea, Dr. Dean sought for, and succeeded in finding, a large number of embryos of *B. stouti* at Pacific Grove, in Monterey Bay, California—the first fairly complete series of myxinoid embryos ever collected. This material enabled him, in 1899, to publish an account of the embryological development of this species. In 1900 and 1901 he made a similar, though less successful, attempt to

\* The Bashford Dean Memorial Volume "Archaic Fishes" Edited by E. W. Guider. Article 3. The Genital System of the Myxinoidea. A Study based on Notes and Drawings of these Organs in *Bdellostoma* made by Bashford Dean. By Prof. J. Leroy Conel. Pp. 63-102 + 4 plates. (New York: American Museum of Natural History, 1931.)

collect embryos of *B. burgeri* along the coast of Japan

While searching for embryos, Dr Dean recorded in his field notes many observations which contribute towards answering the question of the breeding season and spawning period of these species. From the data thus collected he came to the conclusion that the spawning time of *Bdellostoma* is during late August, all of September, and the first three weeks of October. This finding is completely at variance with a statement made by him in 1899, in which he says that "embryos can be obtained during the late fall and early winter in stages which enable me to extend the known season of ovulation throughout the whole year. A time of optimum spawning probably occurs, and this I believe to be the last of spring and the first month of summer." In the absence of more definite data from other workers, these two differing views serve but to emphasise the fact that the spawning time of the Myxinoidea is still unknown.

All investigators in these and allied fields of research will be exceedingly grateful to Prof Conel for collecting and arranging these notes, graphs, and drawings of the late Dr Dean, and to the trustees of the American Museum who have made possible their publication. Here and there in the paper the writer has added some of his own observations and conclusions. For the purpose of presenting more clearly and of emphasising the significance of Dr Dean's work, this was perhaps necessary—even inevitable. Nevertheless, although Prof Conel's contributions consist chiefly of corroborations of Dr Dean's observations, it is unfortunate that not infrequently the reader is provided with insufficient clues to enable him to decide which of them is responsible for a given observation or deduction. G. A. S.

### University and Educational Intelligence

LONDON—The degree of D Sc in Chemistry has been awarded to Mr. A. A. Goldberg (Imperial College—Royal College of Science) for a thesis consisting of three papers entitled (1) "The Synthesis and Orientation of Trichloroanthraquinones and Amino Disulphonates of Anthraquinone", (2) "The Rational Synthesis of 1,3-Dichloroanthraquinone", and (3) "The Reduction of Nitroanthraquinone Sulphonic Acids" (*J. Chem. Soc.*, 1931-32).

Of the State school supervisory agencies used by local education authorities in America one of the most important is the circular letter. A collection of specimen letters, addressed chiefly to rural school teachers, is published as *Bulletin* No. 19, 1931, of the Office of Education, Washington. They give some idea of how the wheels of the State school machine go round, and of the multifarious duties that fall to the lot of the school superintendents, some thousands of whom assembled in February at Washington under the auspices of the National Education Association. The February number of *School Life*, the organ of the Federal Office of Education, is devoted largely to topics of special interest to them.

THE "Hygiene and Physical Education" chapter of the forthcoming Biennial Survey of Education in the United States, 1928-1930, has been issued as *Bulletin* No. 20, 1931, of the Office of Education, Washington, and almost simultaneously has appeared "White House Conference, 1930—a condensed report of America's children, their health, education, training handicaps, etc., as analysed by 1200 experts working on 150 committees", obtainable (price 50 cents) from the office of the White House Conference on Child

Health and Protection, Interior Department Building, Washington, D. C. There has recently been conducted in connexion with this conference an investigation, such as has not taken place since 1923, of American public school medical and dental work and health and physical education, and the results of the investigation are summarised in this bulletin. It appears that in such matters as high school playgrounds, gymnasia and swimming-pools, and health examination of children attending, or soon to attend, elementary schools, there has been during the past seven years a marked improvement. In universities and colleges the answer to "the insistent demand that students should know more about wise living and the care of their bodies" seems to have been in most cases rather perfunctorily met by optional courses in hygiene, and college entrance requirements have, through lack of recognition for entrance credit of physiology and hygiene, tended to distract attention from the needs of health teaching in secondary schools. There has been in recent years a remarkable development of interest on the part of colleges, universities, and teachers' colleges in summer camps and the opportunities they offer of health cultivation.

### Calendar of Geographical Exploration

April 25, 1900—Italian Polar Expedition

Capt. Cagni reached 86° 34' N in 65° 20' E. The Italian expedition of H. R. H. Prince Luigi, Duke of the Abruzzi, had sailed in 1899 in the *Stella Polaris* by way of Franz Josef Land. The winter was spent in Tephtz Bay, Rudolf Island, and in the spring an attempt was made to reach the north pole by sledging over the ice. Frost-bite disabled the Duke, and Capt. Cagni therefore led the northern party, starting on March 10, 1900, with ten men and nearly a hundred dogs. Before losing sight of Rudolf Island, three men turned back—and were never seen again. A second party returned safely from lat. 83° 10' N, but Cagni, with three companions, reached the above point; no land was visible at the farthest north. Cagni had to turn back because the food supply was giving out; the return journey took sixty days, as against forty-five for the outward. Much had been achieved, though the pole itself had not been reached.

April 26, 1848—A. R. Wallace and H. W. Bates

A. R. Wallace and H. W. Bates left Liverpool for Para, where they stayed for eighteen months, and thence made excursions to the Tocantins, Cameta, and the junction of the Rio Negro and the Amazon. Thence Wallace went to the Orinoco, and returned to England in 1852. Bates proceeded up the Amazon to Ega, where he remained for a year. In October 1857, Bates again set out from Para, and settled at Santarem for three and a half years, from which point he made numerous expeditions. For another four years he was at Ega, and then set out on an expedition to the foot of the Andes, but at Fonteboa he was compelled by illness to return, after having travelled 1400 miles up the great river. His book, "The Naturalist on the Amazons", is not only of scientific value, but also has a charm which still attracts the general reader. During his eleven years' stay he collected 8000 species of insects new to science. Wallace's collections, except for some sent on in advance, were lost in a fire at sea on the return journey. In 1854-62, Wallace made a tour in the Malay Archipelago. He divided it into two groups, according as their zoological affinities were Oriental or Australian. A narrow belt of sea, known as 'Wallace's Line', between the Oriental Borneo and

Bali on one side and Celebes and Lombok on the other, indicates an emphatic divergence between the indigenous mammalia of the respective regions

#### April 27, 1404 —Claviyo in Samarkand

Ruy Gonzales de Claviyo, a nobleman of Madrid, left Trebizond. He had set out from Spain in 1403 as an envoy of Enrique III, King of Castile and Leon (1390–1406), to the court of Timur. He was a keen and intelligent observer and kept a detailed record of his travels. From Trebizond he journeyed by land to Tabriz, crossed the Kara Kum desert, and reached Samarkand. He described the 'Iron Gates', the pass through which alone Samarkand could be approached from Afghanistan and the tribute which Timur was thus enabled to exact, and compared it with the 'Iron Gates' near Derbend, which controlled the trade from Persia and was also in Timur's hands. He referred to the entrance of the Oxus into the Caspian, though he himself did not visit this region. A Persian traveller of the period makes the same statement, but the question of the previous course of the Oxus is still unsettled.

#### April 27, 1896 —H. H. P. Deasy in Central Asia

Capt H. H. P. Deasy left Srnagar on the first of a series of expeditions which he continued until 1899. He explored part of the Upper Yarkand valley and a large area south of the Kuen Lun and east of Pagong Lake and Rudok, everywhere making careful surveys and thus doing much to fill in spaces previously blank on the map of Tibet.

#### April 28, 1806 —The Arctic Ice

Capt Scoresby, in the *Resolution*, an English whaling boat, entered the ice in  $76^{\circ}$  N, penetrating it by means of ice saws, and found the open sea beyond. He reached  $81^{\circ} 30'$  N in  $19^{\circ}$  E, the ice being fixed and solid to the north, with open sea to east-north-east and south-east. On board was Scoresby's seventeen-year-old son, William Scoresby, who took command of the *Resolution* in 1811. In 1813 he established the fact that the deep-sea temperature of the polar ocean is higher than the surface temperature. In 1822 he pushed his way through the ice floes that encumber the approach to the coast of east Greenland, and surveyed and charted 400 miles of that coast between  $69^{\circ} 30'$  and  $72^{\circ} 30'$  N. He later carried out researches on terrestrial magnetism, and in 1856 made a voyage to Australia to collect data on that subject. The work of the two Scoresbys threw new light on seasonal ice movements in the arctic.

### Societies and Academies

#### LONDON

Optical Society, March 10 —R. A. Houston. Absorption of light. The intensity of a beam of light at a point in an absorbing medium decreases exponentially as the distance travelled (Bouguer-Lambert law). It holds only for monochromatic radiation, and the ratio of the intensities at two given points is independent of the absolute intensity. This independence might be expected to break down when the intensity is very great, but experimental proof for this is surprisingly slight —E. Gifford. Note on refractive indices. A comparison between the refractive indices and dispersions of certain glasses is made with those of certain specified liquids.

Mineralogical Society, March 15 —F. A. Bannister. The distinction of pyrite from marcasite in nodular

growths. X-ray single crystal and powder photographs show that nodules from the Chalk in the south of England are pyrite. Examination of polished sections of a number of these nodules by reflected polarised light confirms this work, in no case of nodular pyrite yet examined is there evidence of an intimate intergrowth of marcasite and pyrite. Both methods have also been applied to the study of nodules from other localities, including the true marcasite nodules from Wisconsin, United States, and pyrite nodules in shales. Nodular pyrite is far more common than was formerly supposed, whereas nodular marcasite is comparatively rare —L. Hawkes and H. F. Harwood. On the changed composition of an anorthoclase-bearing rock-glass. The vitreous contact faces of a felsite dyke contains anorthoclase inlets which cannot have grown in a liquid represented by the glass. The glass, which shows no outward sign of alteration and exhibits strain birefringence, has taken up soda and water and lost potash and silica. Glasses are more liable to metasomatic change than crystalline rocks —A. E. Maurant. The spherulitic rhyolites of Jersey. The spherulites present a variety of structures. These are described and their origin is discussed, and particular attention is paid to rhythmic growth, of which there are good examples in some of the spherulites —Frederick Walker. An albitite from Ve Skerries, Shetland Isles. A specimen collected from this almost inaccessible group of rocks proves to consist of albite 90 per cent, chlorite (replacing biotite?) 2 per cent, quartz 2 per cent, with accessory titaniferous magnetite and apatite. Texture granitoid. Specific gravity 2.64. Chemical analysis compares closely with those of albitites from the Ural Mountains and from the Assynt district, Sutherland.

#### DUBLIN

Royal Dublin Society, Jan. 26 —Paul A. Murphy and R. McKay. The compound nature of crinkle and its production by means of a mixture of viruses. The naturally occurring potato virus disease known as crinkle is shown to be due to the presence of two viruses, the virus of simple mosaic and a new virus A. When simple mosaic is inoculated into healthy-looking plants of Irish Chieftain, which normally contain virus A, crinkle is produced, and the same result follows when the two constituent viruses are separately introduced into virus-free plants of other varieties. The synthetic disease appears to possess all the characteristics of natural crinkle. A mixture of streak and virus A also produces a form of crinkle, but this is shown to be due to a simple mosaic which generally accompanies streak. The latter has no part in the constitution of crinkle —Paul A. Murphy. A critical review of some recent work on the occurrence of virus complexes in the potato. The view that such naturally occurring virus diseases of the potato as crinkle, mosaic, and streak are compounds of the same X and Y viruses, as suggested by K. M. Smith, and are therefore closely related, has not been established. Differences are pointed out between the Y viruses derived from these three diseases, and explanations are offered to account for them. The Y virus obtained by analysis of streak in Up-to-Date is derivable in part from the simple mosaic which seems to accompany streak invariably, and probably in part from the streak element. Determination of the constitution of virus complexes by analysis is much more liable to error than determination by synthesis. The disease secured from crinkle in certain of Salaman's experiments is shown to have been simple mosaic, and not a reduced crinkle. The possible identity of crinkle and rugose mosaic is discussed.

## EDINBURGH

Royal Society, Feb 15 —J Walton and Jessie A R Wilson On the structure of *Vertebraria* During the latter part of the Palæozoic period the most abundant plant in the southern hemisphere was *Glossopteris* with its tongue-shaped leaves Along with these leaves, and, according to some workers, occasionally found attached to them, are peculiar stems A study of these stems (*Vertebraria*) shows that in structure they agree more with stems of seed plants than with ferns or any other group of plants Since *Glossopteris* has long been suspected of being a seed plant and not a fern, and in view of the supposed connexion between *Glossopteris* and *Vertebraria*, the structural evidence derived from *Vertebraria* is suggestive and is in favour of the supposed connexion between these two plant fossils —G Bond The effect of malnutrition on root structure An earlier investigator reported that decotylation results in an elimination of the pith from the part of the root afterwards formed in *Vicia* and *Phaseolus*, and further induces a reduction in the number of protoxylem rays in *Vicia* These statements have not been confirmed —Isobel M Case The development of the sorus in some species of *Nephrolepis*, together with some observations on points of anatomical interest Within the genus *Nephrolepis* the final position of the sorus varies considerably, from almost marginal to distinctly intramarginal types There is, however, no corresponding difference in point of origin of the sorus, this being in each case slightly superficial, the first sign of soral development being evident at a point five to six cells back from the marginal cell The vascular system of the stem is of an advanced dictyostelic nature The leaf trace is horse-shoe shaped, and consists of a number of separate strands The method of pinna-trace formation is marginal throughout the entire length of the frond —E Boyd The pigmentary system and the dopa reaction By the term 'pigmentary system' is meant the chromogen and a catalytic enzyme or enzymes, which by their interaction produce melanin in pigmented living tissues, and the cellular elements in those tissues which influence or are influenced by the reaction It is suggested that the pigment in differently coloured mammalian hair (reds, browns, and black, etc) is identical, the varying visible colours being the result of differences in physical structure or in deposition and disposition of the melanin in the fibre, while variations in the accomplished degree of oxidation of the basal chromogen may also influence the colour perceptible to the naked eye Evidence is produced to support the nuclear theory of the origin of melanin, in the finding of nuclear pigment caps in the epidermal cells of various breeds of sheep In sections from dominant white sheep no dopa-positive cells can be found in the Malpighian layer, in the fibre sheath, or in the hair bulb; sections from white sheep heterozygous for brown give a diffuse yellowish brown coloration with a few dopa-positive cells, in recessive browns a single layer of small dopa-positive cells is demonstrated in the Malpighian layer and there are other differences It may therefore be possible to evolve a quantitative test to enable a genotypic white to be distinguished from phenotypic white sheep

## COPENHAGEN

Royal Danish Academy of Science and Letters, Oct 30 —August Krogh Secretion of salt through the gills of fishes Processes involving the transport of dissolved substances against a head of pressure are, no doubt, of common occurrence in living organ-

isms, but only in a few cases is it possible to study such processes both qualitatively and quantitatively The experiments undertaken by A B Keys show that salts are given off from fish blood with  $\Delta = 0.6^\circ \text{C}$  through the gills to sea water ( $\Delta = 1.9^\circ \text{C}$ ) The mechanism and energetics of this process are discussed

Nov 27 —Harald Bohr Distribution of values of the zeta-function of Riemann

## CRACOW

Polish Academy of Arts and Letters, Nov 9 — Georges Bouligand Some applications of the theory of ensembles to infinitesimal geometry —L Chamard The Cantor-Minkowski construction —A Kordylewski Occultations of stars by the moon observed at Cracow 1923-30 —W Swietoslowski The application of the phenomenon of azeotropism to the determination of small quantities of impurities —W Swietoslowski and Mile J Szmigielska The determination of the proportion of water in alcohol and in the azeotropic carrier —Mile A Dorabalska, T Niwinski, and Mile E Turska The specific heats of some radioactive minerals Measurements with the adiabatic microcalorimeter —A Skapski and J Kamecki The influence of temperature on the trend of the electrocapillary curve —A Skapski The meaning of the action coefficient of neutral salts according to Szyszkowski, from the point of view of the modern theory of electrolytes —W Jacek The velocity of solution of marble in acids (2) —Mme W Solodkowska and Mile K Rudowska The determination of the heat developed in the course of the germination of seeds —K Dziewonski and A Kleszcz Studies in the fluorene series (4) Synthesis of 1,2-diacetofluorene —A Swaryczewski The crystallisation of ammonium chloride with cadmium chloride —M Ksiazkiewicz The tectonic of the southern part of the Cieszyn zone between the Olga and the Vistula —R Roslonski The value of the annual evaporation in the San basin —J Samsonowicz The supposed appearance of the Carboniferous in the west of Volhynia —Cz Kuzniar The geological structure of the potash deposits at Stebnik —W Domagalski The motor and separating tissues of the floral peduncles of *Spartmannia africana* —K Kaniewski The origin of new species in crosses between tetraploidal types of wheat —Mile J Siwakowna *Ancyrocephalus vistulensis*, a new trematode parasite of *Silurus glanis* —E Kryszczyński The absorption of the mineral compounds of the urine in the cloaca of birds

## GENEVA

Society of Physics and Natural History, Dec 3, 1931 —W H Schopfer (1) A new technique for preparing and mounting the zygotes of Mucorineae The author describes a technique for preserving, mounted in glycerol-gelatine on a microscope slide, all the strains of zygotes arising from a series of experiments —(2) A physiological separation of the phenomena of growth from those of sexuality in a fungus (*Phycomyces*) The author has made a series of experiments from which he concludes that conditions of culture exist which can inhibit sexuality in a non-

definitive and reversible manner, and this without interfering with vegetative development or inversely — M Grosjean and J J Pittard New methods and classification for the rapid determination of minerals The authors construct synoptic tables of minerals in which appear their essential physical properties, colour, hardness, density, fusibility, colour of the streak, and finally the principal chemical and crystallographic properties After a little practice, these tables allow of a rapid determination, by the application of the principle of dichotomic tables

Dec 17—A Liengme Contribution to the study of the human blood groups in hæmophilia From studies made on two families, the author concludes that, contrary to the view now generally held, the character for hæmophilia is not connected with the blood group —E Friedheim Pyocyanine and biological oxidations Pyocyanine, the blue pigment of the pyocyanic bacillus, represents a reversible system of oxidation-reduction Thanks to this property, this pigment has the function of a catalyst in the respiration of living cells such as the pyocyanic bacillus, staphylococcus, pneumococcus, red blood corpuscles of mammals, and cancer cells The increase of respiration observed reaches 2400 per cent —J and L Deshusses Some insects specially harmful to French-Swiss agriculture Besides parasites already known, the authors have recognised seven new species which, in their districts, attack celery, *cône*, fuchsia, apple tree, pear tree, certain varieties of peas, and hot-house plants

## MELBOURNE

Royal Society of Victoria, Nov 12 —Gerald F Hill Australian termites (Isoptera) Biological notes and new species This paper contains notes on the biology, distribution, and synonymy of several species of Australian *Calotermes*, *Coptotermes*, *Heterotermes*, and *Eutermes* Four new species, *Calotermes spoliator*, *Coptotermes tullyardi*, *Heterotermes intermedius*, and *Eutermes dixonii* are described —Bernard C Cotton and C J Gabriel Australian Unionidæ The authors comment on the difficulty of classifying the Australian forms, owing to the variability of the individuals which constitute a species and the tendency of one species to merge into another Ten species and a variety are enumerated, and two new genera, *Propehyridella* and *Protohyridella*, are suggested —A B Edwards The geology and petrology of Warburton This includes an acid suite of igneous rocks (rhyolites, dacites, and granodiorites) The igneous rocks intrude a series of Silurian sediments, and being contiguous with similar igneous rocks in the Blackspur area, are considered to be of Upper Devonian age The granodiorite is interesting on account of the presence of quartz nodules

## ROME

Royal National Academy of the Lincei, Dec 6 —G Fubini A theorem of Severi for analytic functions of two variables —E Bompiani Intersection invariants of two oblique curves —Enea Bortolotti Allied connexions associated with an  $(n+1)$ -pla of congruences in an  $n$ -dimensional variety —G Barba Metric transports —P Tortorici Maxima and minima of convex functions —Vladimiro Bernstein Ultra-convergence of certain series of Dirichlet (2) —L Godeaux An algebraic surface —M Kourensky The integration of equations which determine the conjugated functions of Beltrami —Maria Previatti Bortolozzi The equation of the asymptotic of a  $V_2$  with  $\sigma_2$  of three dimensions —Luigi Crocco A maximum value of the coefficient of heat-transmission by a plane lamina to a flowing fluid The ordinary theory of

heat transference between a plane lamina and a flowing fluid ignores entirely the influence of the heat developed by friction on the temperature gradient adjacent to the lamina and on the coefficient of transmission With high velocities this frictional heat is not negligible, and consideration of this case shows that the heat transference is governed by the law that holds when the frictional heat is negligible, provided that the temperature of the fluid is taken to be that to which it would be carried by adiabatic arrest —A Bellugi Further consideration of the gravimetric depressions in the Paduan valley —E Segrè Quadrupole lines in X-ray spectra All the known forbidden lines of X-ray spectra may be explained as quadrupole irradiation, which, in the case of X-ray spectra, is much greater than with optical spectra, and preponderates over all other causes for the appearance of forbidden lines It is, therefore, considered that the forbidden lines of X-rays are to be attributed to quadrupole transitions —L Mascarelli, D Gatti, and M Pirrona Contribution to the knowledge of diphenyl and its derivatives (10) Influence of certain substituents in the 2'-position on some reactions of  $\text{NH}_2$  in the 2-position —A Ferrari and C Colla Chemical and crystallographic investigations on complex nitrites (2) Double nitrites of potassium and nickel and of potassium and cobalt The compounds to which the formulæ  $6\text{KNO}_2$ ,  $3\text{Co}(\text{NO}_2)_2$ ,  $\text{H}_2\text{O}$  and  $2\text{KNO}_2$ ,  $\text{Co}(\text{NO}_2)_2$ ,  $\text{H}_2\text{O}$  have been attributed, are merely the cobaltinitrite contaminated with cobalt hydroxide This hydroxide is probably formed in the hydrolysis of the cobaltous nitrite, which gives also the nitrous acid causing the oxidation of the bi- to ter-valent cobalt and hence the formation of the cobaltinitrite The compound  $\text{K}_4\text{Ni}(\text{NO}_2)_6$  is monometric with a lattice of side  $a=10.49 \text{ \AA}$ , that of potassium cobaltinitrite is  $a=10.32 \pm 0.02 \text{ \AA}$  The close approximation between the values of the unit cell constants and the positions of the photogram lines for these two compounds indicate the existence between them of a close isomorphous relationship, in spite of the different numbers of atoms in the two molecules —L Sanzo Egg and first larval stages of *Myctophum Gemellari* Cocco (= *Scopelus Gemellari* C and V) —G Brunelli New contributions to the biology of lagoons —A Orrù Observations on the water-content of the white and yolk of hens' eggs during the development of the embryo During the incubation period, the white of hens' eggs undergoes gradual dehydration until the twelfth or thirteenth day, after which it increases in water-content continuously to almost the original value just before the shell breaks On the other hand, the yolk takes up water for twelve days and later suffers rapid dehydration, but not to such an extent as to bring the moisture content to the value it has in the quiescent egg —Ettore Marchiafava Obituary notice of Antonio Dionisi

## VIENNA

Academy of Sciences, Dec 17 —J Kissner, R Stasser, E Kiffe, and S Gollner Researches on bending due to wounds in dicotyledon seedlings and their material causes To one-sided injuries the seedlings react by bending, the reaction being greatest with stems in active growth A growth substance is formed in the end-buds of dicotyledon seedlings Removal of these end-buds inhibits growth, but growth is stimulated again on replacing the end-buds or by agar into which the growth-substance has diffused There appears to be also a wound-substance the action of which is contrary to that of the growth-substance —J Kissner and P Popp Growth and differentiation processes in dicotyledon

seedlings after continued removal of buds After removal of buds in *Helianthus* the leaves grew notably; this was due to growth in size of the leaf cells—J Kisser and M Lorenz Chemical stimulation of the germination of *Pisum* and *Triticum* under optimum germination conditions As stimulants the best were manganese salts and ethyl alcohol—J Kisser Critical remarks on the nature and the concept of seed germination—A Jagersberger Measurement of light transmission through cathode-sputtered silver films—L Schmid and R Falke Measurements of the viscosity of carbohydrates in liquid ammonia, in formamide and in water—A Kohler (1) Granite of type Eisgarn from the north-western Waldviertel (2) The monzonitic quartz-mica-diorite of Dornach in Upper Austria—H V Graber Comparative observations on the eruptive rocks of the circum-Adriatic arc—E Haberer Graptolites from the Upper Silurian of the Carnic Alps (2)—O Reithofer Report on the conclusion of the rift measurements in the wider neighbourhood of Kofels in the lower Oetz valley—O Sickenberg Geological researches in the northern Osterhorn group (Salzburg)

### Forthcoming Events

#### FRIDAY, APRIL 22

ROYAL ANTHROPOLOGICAL INSTITUTE (Human Biology Research Committee), at 5 30—Prof J B S Haldane Present Knowledge concerning Blood Groups  
SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (Annual General Meeting) (at Waldorf Hotel, Aldwych), at 6 45, followed by dinner at 7 30—Sir Robert Horne Currency and Prices (Address)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof J B S Haldane Hereditary Transmission of Acquired Characters

#### SATURDAY, APRIL 23

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin)—Prof J K Catterson-Smith Everyday Uses of Electricity (Faraday Lecture)

#### MONDAY, APRIL 25

ROYAL SOCIETY OF ARTS, at 8—Prof J C Drummond Recent Researches on the Nature and Function of Vitamins (Cantor Lectures) (2)

#### WEDNESDAY, APRIL 27

ROYAL SOCIETY OF MEDICINE (Comparative Medicine Section), at 5—Annual General Meeting  
NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (simultaneously in London and New York) (at the Science Museum), at 5 30—W W Mason Trevithick's First Rail Locomotive—Hon Charles L Chandler Early Shipbuilding in Philadelphia  
LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (at Museum, Leicester), at 7 30—Annual General Meeting  
ROYAL SOCIETY OF ARTS, at 8—H Ramsbotham Education for Commerce (Lecture).

#### THURSDAY, APRIL 28

ROYAL SOCIETY, at 4 30—Discussion The Structure of Atomic Nuclei To be opened by Lord Rutherford, followed by, probably, Dr J Chadwick, Dr C D Ellis, Prof R H Fowler, Prof J C McLennan, Prof F A Lindemann, and N F Mott  
INSTITUTION OF CIVIL ENGINEERS (Birmingham and District Association) (at Chamber of Commerce, Birmingham), at 6—Annual General Meeting  
AT B M A HOUSE (Tavistock Square)—Dr J H Sequeira

The Educational Aspect of Public Health Work in the Tropics (Chadwick Lecture)

#### FRIDAY, APRIL 29

ROYAL ASTRONOMICAL SOCIETY, at 4 30—Geophysical Discussion The Maintenance of the Earth's Electric Field To be opened by Dr F J W Whipple, and continued by Dr G C Simpson and others  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof H. Hartridge The Rival Theories of Hearing

## Magic and Administration in Africa

IT is inevitable that the anthropologist should suffer a feeling of disillusion, almost at times mounting to the level of discouragement, when he looks back on the history of our official relations with 'native' races during the period of, say, the last fifty years. The lessons of his science, in his eyes plain so that he who runs may read, have been neglected time and again. Racial prejudices and tribal customs and beliefs have been flouted. Sometimes they have been ignored through lack of knowledge, sometimes deliberately set aside or suppressed. Even where there has been little or no overt resistance, tribal organisation has been weakened, with a consequent deterioration in the character of the people, but often acceptance of the decree of the European administration has been enforced only by a heavy expenditure of blood and treasure, of which both sides have had to bear the cost.

In many instances much that has proved detrimental to the subject race and a source of innumerable difficulties, and even of danger, to their rulers might have been avoided had the administration been inspired by the sympathetic understanding which would have followed from a scientific knowledge of the social and religious pattern in the everyday lives of those they governed. Individual officers have not necessarily been to blame. Usually without any scientific training in the study of backward peoples, many of them acquired empirically an adequate knowledge of native institutions, and at times, especially in India, their knowledge has probed deep into native ways of thought and action. Yet the whole trend of administration either attained no more than the preservation of law and order without any specific idea of direction, or at best aimed at the amelioration of the conditions of the native in accordance with European ideals. Customs out of harmony with, or repugnant to, these ideals, such as cannibalism, human sacrifice, or head-hunting, were sternly suppressed without thought of their place or meaning in tribal life, even as missionary influence discouraged or forbade polygamy and the bride-price in Africa without heed or knowledge of the inevitable disintegration of the tribal, social and economic system which was bound to ensue.

When the anthropologist, in urging the application of the results of anthropological science in practical affairs, deplors the suppression of custom in certain instances, it must by no means be taken that he approves these practices or advocates their

No 3261, VOL 129]

preservation, however interesting or vital they may be for the academic study of man and the development of his institutions. It is their suppression without due regard to their function in the social organisation that he deplores. Head-hunting, for example, among certain peoples of Papua or in the Naga Hills of Assam, was of vital significance in tribal life. Suppression would have broken economic, social, and religious bonds in the community. A wise policy in administration, taking cognisance of the wide ramifications of the custom, retained the form of the institution, while securing the substitution of a pig or other animal for the human victim. A grasp of the essential function of the custom averted the disaster which would have followed its total suppression. The tribal organisation was saved from the danger of disintegration, and faith in the essential fair dealing of the administration was assured.

In Africa the problem of the attitude of the administration towards native custom is of the greatest moment on account of both the inherent difficulty of the question and the magnitude of the issues involved. A recent case of witchfinding in Kenya, to which reference is made in a well-informed article by Frank H. Melland which appeared in the *Times* of April 13, and subsequent letters from Lord Lugard and others in later issues, serves to illustrate the difference in outlook between white and black which lies at the root of the difficulties of a European administration in dealing with the native. The Kenya case has attracted considerable attention owing to the number of defendants involved, but it is only one of many similar with which the authorities in different parts of Africa have had to deal within the last few years. In this latest case, a witch was beaten to death with staves by the members of the tribe, after she had been smelled out by the witchfinder. This action was in accordance with tribal custom, but as a result sixty persons were arrested, put on trial for murder, and condemned to death at Nairobi.

From the strict point of view of the law, the proceedings at Nairobi were in order, and the sentence awarded a penalty in accordance with the law. Witchfinding is forbidden by law, and the punishment of a witch by death as the outcome of a witchfinding ceremony is technically murder. From the point of view of the native, however, the law of the European administration is both illogical and unjust. The fact that in this and other cases the sentence has been remitted or commuted to a term of imprisonment is irrelevant. Nor is it of any avail to attempt to meet the native with the argument

that the witchfinder is seeking something that does not exist. The majority of the natives of Africa hold firmly to the belief in the reality of magic. To them the evidence of innumerable happenings in everyday life bears out their assurance of its powers, and the deaths and other misfortunes of individuals are proof positive of the malevolent efficacy of the witch.

It is, of course, common knowledge among those familiar with the African, that magic enters deeply into his life, but how this belief and its relation to witchfinding reacts in unexpected directions and incidentally affects the relations with Europeans may be illustrated further by the difficulties which arose in the South African mines some twenty-five to thirty years ago. One of the elements which contributed very largely to the shortage of native labour then experienced in the mines was the fear of the magic which, in native conception, was the cause of the high death-rate, and the prohibition by the authorities of the 'throwing the bones' by means of which the magician who had caused the deaths in individual cases, was smelled out. It was their belief that death was caused solely by magical agency, and even now no members of the Bathonga tribes who leave their country to work in the mine and elsewhere are readmitted without an elaborate purification ceremony to remove the evil magic which clings to them and might bring death and pestilence to other members of the tribe.

Witchfinding, however, is only one of the various means by which the native seeks to protect, not himself alone, but also the whole of his group from the influence of evil magic. To forbid witchfinding and to inflict the death penalty on those who meted out the customary retribution on the witch—in the eyes of the tribe a murderer and worse—is as irrational a proceeding in the eyes of the native as it would be Gilbertian in a civilised community if the detective who tracked down a criminal, and the court that inflicted punishment, thereby became liable to the extreme penalty of the law.

It might be thought that in course of time knowledge of the penalty inflicted by the law will have its effect and the employment of witchfinders die out. This is improbable, at least within a reasonable time, for more reasons than one. The example of what happened in England is instructive in this connexion. Even in the middle of the eighteenth century, a hundred years after the Essex witchfinder Hopkins had been discredited and long after witchcraft as such had ceased to be recognised in law, certain individuals caused the death of a suspected witch by the ducking test, and were convicted

of murder As both Lord Lugard and Mr Melland point out, the situation in regard to witchcraft in Africa calls for an alteration in the law Unless, moreover, the law recognises the African point of view, no measure is likely to provide a solution However much it may be repugnant to European ideas, and whether magic be regarded as an illusion or not, the African's belief in magic must at least be accepted as a reality

The acceptance of witchcraft and magic as something more than futile superstition which may be disregarded or swept aside goes deeper than a mere concession to the native's failure as yet to grasp the facts of existence as the European sees them Nor should such beliefs be treated lightly if, as is conceivable, cases of suspected witchcraft were made the subject of inquiry, instead of being left, as they are now, as a matter purely of concern to the native, unless they result in some action which brings him within reach of the European's law In present conditions, the only element in the witchcraft superstition of which the administration takes cognisance is the witchfinding and the execution of the witch—the very means whereby the native gives expression to the solidarity of the group, and tribal society acts in self-preservation against an anti-social force

Tribal solidarity, and with it tribal discipline and the authority of the chief, are being assailed on many sides by the rapid changes now taking place in Africa Since the War, the increased facilities for transport have made the native more mobile He goes far afield to find employment and in increasing numbers He earns money as an individual, whereas formerly his earnings were the property of his group With this individual wealth at his disposal for furnishing the bride-price, no longer in many cases payable in cattle, he marries without reference to his family or tribal group, and often when he returns home he is a wealthier man than his chief

What may be the effect in the modification of native institutions of these varied influences brought into play by the impact of white civilisation is now being made the subject of a much-needed inquiry by the International Institute of African Languages The African is being hurried from his status of merely a component part in a unitary group, the family or tribe, into that of an individual independent of traditional ties, before he has had an opportunity of learning the responsibilities of the individual Administrative action which in any way hastens this process prematurely may precipitate disaster

(1) **T**HE author of this book requires no introduction to those who have followed his work on the decay of timber As may be expected in a book written by a professor of the University of Idaho, forest pathology is dealt with almost entirely from the point of view of North America, but as the causes of disease and decay, and the control measures necessary, are largely common to other regions, the book should be of interest to foresters generally

The book is divided into three parts Part 1 (introductory) contains a classification of tree diseases, and deals with the factors influencing disease, the relative importance of tree diseases, economic losses, and symptoms of disease and decay Part 2, which bears the title "Forest Pathology", deals with various forms of injury, such as that caused by frost, drought, insolation, smoke, and other agencies, and describes certain specific diseases, it concludes with a short account of control methods Part 3, headed "Wood Pathology", deals with the decay of timber, both converted and unconverted

The book has a practical outlook, and the fungi

most effectively dealt with are those of special economic importance, for which reason it should prove of service more particularly to the practical man. It is well illustrated, and contains useful references to literature at the end of each section.

(2) This is a second edition of Prof Toumey's "Seeding and Planting in the Practice of Forestry" (1916), revised and enlarged by Prof Korstian. In general arrangement the book follows the first edition fairly closely, and is divided into two main parts, the first dealing briefly with the silvicultural basis of regeneration (including methods of reproduction, choice of species, spacing, and the composition of the crop), and the second and by far the larger part dealing with the formation of forests by seeding (sowing) and planting. This part goes in considerable detail into the technique of artificial regeneration, including the collection, extraction, storage, and testing of seed, the preparation of planting sites, the establishment of plantations by direct sowing and transplanting, and nursery practice.

In some respects the new edition is more definitely an American textbook than the original one, since most of the additions refer to American practice, nevertheless, it should prove of much value to British foresters, even though some of the methods described are scarcely applicable to British conditions, while some of the methods practised in Great Britain are not dealt with. It is interesting to note that more use is made of horse-drawn implements in American than in British forest nurseries. There are useful references to bibliography at the end of each chapter, the illustrations are good, and the book is attractively got up.

(3) Three volumes of the Comte Goblet d'Alviella's "Histoire des bois et forêts de Belgique" have already appeared. The present volume deals with communal and private forests in the Netherlands during the seventeenth and eighteenth centuries, and is in a sense supplementary to vols 2 and 3, which deal with State forests during the same period. This period is important in showing a sudden transition from the old feudal system, which had an intimate bearing on the forest, to a new regime brought about by legislation which democratised it. This radical political change, although it inaugurated an era inimical to the forest, did not effect an immediate transformation in methods of silviculture and management, since here, as elsewhere, economic rather than political considerations had a deciding effect on the production, and thus on the conservation and treatment, of the forests.

Under the old regime, forestry was dominated by the demand for (1) oak timber for construction, agricultural purposes, and shipbuilding, and (2) charcoal for the metallurgical industry, which had been much developed since the sixteenth century and required material of moderate size in large quantities. The system best adapted to meet these requirements was coppice with standards, and hence it was the one almost exclusively employed. In spite of political changes it continued long after the end of the old regime, although there were drastic administrative changes in the direction of centralised control. The author's aim has been to give a comprehensive view of the development of forestry during the period in question without entering into minute details, and he has produced an authoritative work which will be of much interest to foresters and historians alike.

(4) The first edition of Dallimore and Jackson's valuable "Handbook of Coniferae" appeared in 1923. In the present edition the opportunity has been taken to include in an appendix descriptions of a number of species, varieties, and hybrids omitted in the first edition, together with short descriptions of the more important new species brought to light in recent years chiefly as the result of exploration in China and elsewhere. Another innovation is the inclusion of a list of synonyms, giving the correct botanical names under the Vienna rules, of a number of species, of which the names in common use among arboriculturists are retained in the text. Thus, to take a few examples, *Abies pectinata* DC becomes *A. alba* Miller, *Araucaria imbricata* Pav becomes *A. araucana* K Koch, *Larix europæa* DC becomes *L. decidua* Mill, and *P. Laricio* Poir becomes *P. nigra* Arn. The use of generic instead of family headings on the right-hand pages is a definite improvement. This book is likely to retain its value as a standard work on conifers, and none interested in this subject can afford to dispense with it. If there is one suggestion that might be made, it is that in the next edition the opportunity might be taken to revise the keys.

(5) Prof Dengler's "Ökologie des Waldes" is a separate issue of Part 1 of his larger work, "Waldbau auf ökologischer Grundlage", of which Part 2 deals with silvicultural technique. As the title denotes, the ecology of woods is taken as the basis of silviculture. The first section deals with the forest as a vegetation type, considers its relationship to other types of vegetation, and gives a brief account of forest types throughout the world, from tropical to polar and alpine regions. This is followed by a

more detailed account of the natural distribution in Europe and Western Asia of the principal German trees and the development, prehistoric and historical, of German forests. This section concludes with an account of the present distribution of forests in Germany, with their chief component species.

The second section contains a discussion of climatic and edaphic factors in relation to tree growth, and touches on the question of local races. A summary is given of the results of work on forest soils carried out in recent years by various investigators. An interesting diagram, based on the work of Hartmann, shows the range of hydrogen ion concentration of a number of common herbaceous and shrubby forest plants: this demonstrates, for example, the intolerance to acid conditions of *Geranium Robertianum*, *Brachypodium sylvaticum*, and *Dactylis glomerata*, the acid tolerance of *Vaccinium Myrtillus* and *V. Vitis idæa*, and the wide range of tolerance of *Hypnum Schreberi* and *H. purum*. A short account of the physiological life-history of the forest completes the volume.

The scope of this work is mainly limited to German conditions, and the literature cited is almost entirely that of German-speaking countries; nevertheless, the book should prove of value to students of the fundamental principles of silviculture in other countries.

### The Geological Age of *Pithecanthropus*

*The Age of Pithecanthropus*. By Dr. Ir. L. J. C. van Es. Pp. xii + 142 + 4 plates. (The Hague: Martinus Nijhoff, 1931.) 8 guilders.

LITTLE is known about the exact geological age of the oldest fossil human remains hitherto discovered, and every contribution to the subject is welcome. The age especially of the most primitive ancestral man, *Pithecanthropus*, found by Prof. Dubois in a river deposit in Java, has already been much discussed without any definite conclusion. We are, therefore, glad to receive a most valuable small volume on the Tertiary geology of Java by Dr. L. J. C. van Es, who seems to prove that this remarkable fossil dates back to the Lower Pleistocene period. Dr. van Es bases his work on the researches of Prof. E. Dubois, K. Martin, and G. A. F. Molengraaff, to whom he dedicates his publication. He has studied thoroughly the geology of Java, and he illustrates his description by a series of sections and maps, which have been prepared with the help of the Chief of the Geological Survey of the Netherlands Indies.

Since the beginning of the Upper Miocene period at least, there has always been much volcanic activity in the region of Java, and extensive volcanic breccias and tuffs are associated with the deposits containing corals and marine shells, up to those of the Middle Pliocene. They then occur also with lake and river deposits of Upper Pliocene, Pleistocene, and more recent date. There have indeed been many alterations in the level of the land and sea, and there seems to have been a connexion with the Asiatic continent, through Sumatra, in the Upper Pliocene, when land mammals, such as the primitive elephants *Mastodon* and *Stegodon*, *Hippopotamus* and *Cervus*, first invaded Java. The successive marine deposits which now form part of the land are marked by an increasing percentage of existing species of shells among the fossils, as might be expected. It is thus possible to identify them even when they are not seen directly superposed.

The river deposit at Trinil, in which *Pithecanthropus* was discovered, rests unconformably on a marine formation, which is shown by its fossils to be of Middle Pliocene age. The gap in the geological series indicated by the unconformity is filled in other districts by marine deposits, which contain 66-70 per cent of existing species of shells and are therefore Upper Pliocene. Hence the conclusion, that if a marine formation equivalent in age to the Trinil river deposit were found, it would contain more than seventy per cent of existing species of shells and must be regarded as Pleistocene. The percentage of existing species of freshwater shells in the Trinil deposit itself supports this conclusion, and as the associated land mammals (*Stegodon*, *Hippopotamus*, etc.) are much like those in the Lower Pleistocene Nerbada river deposits of India, *Pithecanthropus* evidently dates back to the beginning of the Pleistocene period. A. S. W.

### Nature and Man in Arabia

*Arabia Felix Across the Empty Quarter of Arabia*. By Bertram Thomas. With a Foreword by T. E. Lawrence and Appendix by Sir Arthur Keith. Pp. xxix + 397 + 48 plates. (London and Toronto: Jonathan Cape, 1932.) 25s. net.

THIS book embodies so many important contributions to the common stock of scientific knowledge that the reader marvels that one man should have been able, within the period of twelve months, unaided by public funds or private beneficence, to accomplish so much. Mr. Bertram Thomas, who crossed the great empty quarter of

Arabia, an area hitherto wholly unknown, as great as France and Germany combined, just a year ago, approached his task in a purely scientific spirit, after years of patient preparation. Having learned on board H.M.'s ships to fix his position by the stars, he has produced an excellent map, full of topographical and other details, which would do credit to a trained survey party. He was at pains to measure heads with callipers, and to describe systematically the features of the tribes he encountered, hitherto wholly unrecorded, and in a valuable appendix Sir Arthur Keith and Dr Krogman discuss the anthropological material he has amassed, on which they place a high value. Mr Thomas collected everything he saw, and preserved his specimens so effectively that Dr Calman and his colleagues at South Kensington, who have contributed another lengthy and valuable section, have been able to describe a baker's dozen of specimens new to science, and very many hitherto unrecorded in Arabia.

The geological results are meagre—due to the unpromising uniformity of the formations traversed, but include a meteorite and a valuable series of specimens of rocks and sands, with an analysis of the water in a score or more of wells along the route traversed.

Perhaps, however, the most important contribution to science is the author's description of 'singing sands'. Lord Curzon, in his "Tales of Travels", published in 1923, brought together all known sources of information on the subject, but records nothing so circumstantial as Mr Thomas's experience.

"We were floundering", he writes, "through heavy dunes when the silence was suddenly broken by a loud droning on a musical note. I was startled for the moment, not knowing the cause."

"The hour was 4.15 P.M., and a slight north wind blew from the rear of the cliff."

"Before this, in similar winds, we had passed many such cliffs, but they had emitted no sound, only the light surface sand being carried up the gentle windward slope to spill like smoke over its top. The leeward face of the cliff was a fairly steep slanting wall, and I looked in vain for a more funnel-shaped sand gorge that by some rushing wind action might account for so great a volume of noise. The usual term 'singing sands' seems to me hardly appropriate to describe a sound indistinguishable from the siren of a moderate-sized steamship. The noise continued for about two minutes and, like a ship's fog-signal, ended as abruptly as it had begun."

This description raises very interesting issues. The question was first scientifically discussed by No 3261, Vol. 129]

C. Carus Wilson,<sup>1</sup> who ascribed the phenomenon to "the rubbing together of the surfaces of millions of perfectly clean grains of quartz, free from angularities, roughness, or adherent matter, investing the grains", he adds that, "though the vibrations emitted by the friction of any two grains might be inaudible, those issuing from millions approximately of the same size would give an audible note."

Two American experts, Drs Bolton and Juhen, on the other hand, claimed<sup>2</sup> that—

"The true cause of the sonorous property is connected with thin pellicles or films of air or of gases thence derived, deposited, and condensed upon the surface of the sand-grains during gradual evaporation, after wetting by the sea, lakes, or rains. By virtue of these films the sand-grains become separated by elastic cushions of condensed gases, capable of considerable vibration. The extent of the vibration and the amount and tone of the sound thereby produced, after any quick disturbance of the sand, is largely dependent upon the forms, structures, and surfaces of the sand-grains, and especially upon their purity or freedom from fine silt or dust."

This explanation postulates some degree of previous moisture, induced or exhausted by evaporation. It is tenable in relation to beaches, but not to dunes.

Poynting and Thomson, on the other hand ("Sound"), offer the following explanation:

"There is an arrangement of minimum volume for a number of equal spheres in contact. We may suppose the sand to consist of equal spheres arranged, when undisturbed, so as to occupy minimum volume. When disturbed the mass may pass through many successive minima of volume before coming to rest, and if we can suppose the time occupied in passing from one minimum to the next is constant, a musical note should issue."

None of these explanations seems to cover the production of sound like a ship's siren, and it appears more probable that electrical phenomena may be involved.

These, and many other matters of interest, such as tribal customs, exorcism, marriage, birth and death, clothing and food, the dietetic value of raw gastric juices of camels and gazelles, invest the book with high scientific interest and eugenic significance.

It remains to say that the book is finely written, illustrated by a wealth of photographs which show the author to be no less competent with his camera than with pen, and adorned with a wealth of stories which go to prove that the inhabitants of this part

of Arabia, both male and female, are freer than we are from the bonds of convention in some vital matters, such as sexual relations and taboos, though still in bondage in other directions to ghostly fears and the terror of the unknown

### Universities of the British Empire

*The Yearbook of the Universities of the Empire, 1932* Edited by Sir H Frank Heath Published for the Universities Bureau of the British Empire Pp xiv+953 (London G Bell and Sons, Ltd, 1932) 15s net

BEFORE 1914 the only general directory of the staffs of the British universities was in the German yearbook of the learned world, "Minerva" It was in 1912 that the late Sir George Parkin, then organising secretary of the Rhodes Trust, urged upon the members of the first congress of the universities of the British Empire that they ought to arrange for the setting up of a central office charged with the duty, among others, of producing a yearbook The idea found acceptance and the "Universities Yearbook" has now become a valuable aid to intercourse in the sphere of science and higher education between the countries belonging to the British Commonwealth of nations

The main concern of the 1932 issue of this "Yearbook", as of its predecessors, is to provide, (1) in respect of each of the universities (seventy in number), a directory of its administrative staff and the professors and lecturers, etc, in each of its fields of study, a description of its material equipment, organisation, conditions of graduation, etc, and a summary of events of the past year, (2) a general account of the universities of each national group in their relationship to one another and to the national system of education, (3) particulars of open post-graduate scholarships, etc, and of centres of scientific research and scientific information

An interesting new feature of this year's issue is a short bibliography giving particulars of books dealing with the British universities and with facilities for study abroad, but not including (as it well might) references to important articles that appeared during the past year in periodicals The chapter on the Australian universities has been rewritten and brought up to date by Prof J T Wilson, professor of anatomy at the University of Cambridge and formerly Challis professor of anatomy at Sydney. The result is not such an intriguing story as the Canadian chapter (revised

for the 1931 issue), but all these university group surveys, including those for the British Isles, South Africa, and India, are eminently readable essays whether taken singly or together

The very useful appendix describing centres of scientific research and information, for the most part not directly connected with universities, has been expanded and now covers fifty-five pages Like other annual publications, the "Yearbook" exhibits a tendency to increase in bulk with advancing years, but, thanks to improvements in arrangement and indexing, this has not had the effect of making the search for any particular item of information more difficult Succinct and lucid, it is fit to take a place in any collection of quick reference books dealing with the cultural life of the English-speaking world

### Short Reviews

*Reports of the Progress of Applied Chemistry* Issued by the Society of Chemical Industry Vol 16, 1931 Pp 748 (London Society of Chemical Industry, 1932)

"Bis dat qui cito dat" is a true saying, which applies to no publications more forcibly than to annual reports Again the report on the progress of applied chemistry, as comprehensive and as invaluable as ever, has been published early in the year following that reviewed The contents are as follows general, plant, and machinery (R E V Hampson and J N Vowler), fuel (J G King); gas, carbonisation, tar, and tar products (H Hollings and W A Voss), mineral oils (A W Nash and A R Bowen), colouring matters and dyes (L J Hooley), fibres, textiles, cellulose, and paper (V E Yarsley), bleaching, dyeing, printing, and finishing (P E King), acids, alkalis, and salts (A Proven), glass (M Parkin), refractories, ceramics, and cements (J H Chesters and W J Rees), iron and steel (A L Norbury and F K Neath), non-ferrous metals (A R Powell), electrochemical and electrometallurgical industries (H T S Britton and R A Robinson), oils, fats, and waxes (E R Bolton and K A Williams), paints, pigments, varnishes, and resins (G C Attfield, S Marks, L R Hickson, and W Singleton), rubber (T R Dawson), leather and glue (W R Atkin), soils and fertilisers (E M Crowther), sugars, starches, and gums (J P Ogilvie), fermentation industries (H Li Hind and F E Day), foods (G D Elsdon), sanitation and water purification (A Parker), fine chemicals, medicinal substances, and essential oils (E Stedman), photographic materials and processes (A Batley and E E Jelley) The participation of members of the staffs of official organisations—H M Fuel Research Station, the British Launderers' Research Association, the British Cast Iron Research Association, the Research Association of British Rubber Manufacturers, and the Water Pollution Research section

of the Department of Scientific and Industrial Research—is noted with satisfaction

Only too frequently is it necessary to refer to the effect of the industrial depression on activity in the chemical industries, but the degree to which the flow of new knowledge has been maintained is a factor of great significance for the future. Already many definite improvements in the situation as it affects those industries are recorded. Among many matters of general interest referred to are the collapse of the price and production agreement between the Chilean and synthetic nitrogen interests and the operation of a price-fixing agreement reached between the Russian, Columbian, Canadian, and South African producers of platinum

A A E

*A Descriptive Petrography of the Igneous Rocks*  
By Prof. A. Johannsen. Vol. 1. *Introduction, Textures, Classifications and Glossary*. Pp. xxii + 267. (Chicago. University of Chicago Press, London. Cambridge University Press, 1931) 21s net

In this first volume the author provides an introduction to the science of petrography. After dealing with the constituents (minerals), and their relations (textures), he gives in summary some twenty-five systems of classification of the igneous rocks. As many of these are now of historical interest only, he rightly pays more attention to those of present practical importance. Thus the systems of Osann and Niggli, the American normative system, and the author's own, which the second volume will fully illustrate, have each a chapter devoted to them, whilst those of Rosenbusch, Zirkel, and Shand are adequately described. Most of them are illustrated by examples, and as the same rock analysis is used in several, a very fair comparison may be made. No formal criticism of the different methods is ventured upon. Two admirable glossaries of mineralogical and textural terms with sundry tables and two indexes complete the volume.

The book is well printed and illustrated, the selection and reproduction of the photomicrographs illustrating textures are all that could be desired. An interesting feature is the inclusion of photographs, with short biographies, of the authors of the more important classifications. Throughout the work abundant references to original sources are made, and the text is enriched with many quotations. It is pleasing to note that where the author has been unable to check a reference it is starred. The errata noted are exceedingly few, on p. 130, quantitative has been used for qualitative, and on p. 157 Orders 1 and 2 should be 1 and 4.

The classification advocated by the author is based on the mineral composition of the rocks as determined in thin slices. Four classes are recognised from the relative proportions of light and dark coloured constituents, division into orders depends on the character of the plagioclase present, whilst further subdivision into families and sub-families is determined by the proportions of quartz or felspathoids, or the ratio of potash felspar to

plagioclase. Certain new terms and names, built on the 'portmanteau' method, are suggested. The full exposition in the second volume will be awaited with interest.

*A Monograph of the Recent Cephalopoda based on the Collections in the British Museum (Natural History)*. Part 2. *The Octopoda (excluding the Octopodinae)*. By G. C. Robson. Pp. xi + 359 + 6 plates. (London. British Museum (Natural History), 1932) 20s

THIS work gathers into one volume practically all the available knowledge of the Octopoda (exclusive of *Octopus* and some allied genera monographed in Part 1 in 1929), and includes a great deal of new information due to the author's comprehensive studies of these animals, not only in the British Museum, but also in Paris, Monaco, Berlin, Leyden, and elsewhere. Our knowledge of the whole group is definitely advanced, so that it is now possible to review the systematic interrelationships of the Octopoda with some confidence.

Apart from the Palæoctopoda, based on *Palæoctopus*, the only known fossil octopod, which has been re-examined and yields fresh evidence, three suborders are recognised, the Vampyromorpha, which are the least specialised and apparently most archaic group, the Cirromorpha (*Cirroteuthis*, *Opisthoteuthis*, etc.), and the Incirrata. This last group includes forms more familiar to the general naturalist, such as *Argonauta*, *Octopus*, and *Eledone*. The species commonly associated under *Eledone* prove to be a polyphyletic group now distributed among Octopodidae and Bathypolypodidae.

The chapter on "Classification and Evolution" is of special interest, and considerable ingenuity is shown in distinguishing resemblances due to convergence from those due to relationship. In some places the general discussion is a little vague, but definite results are reached in most of the major problems. The systematic part, which occupies about three-quarters of the volume, is throughout excellent, and, so far as we have been able to test it, wholly trustworthy.

*Health and Social Evolution* (Halley Stewart Lectures, 1930) By Sir George Newman. Pp. 200. (London. George Allen and Unwin, Ltd., 1931) 4s 6d net

THIS comprehensive review of the health of the people, and the gradual recognition of public health as an aim of State activity, shows the hand of a master throughout. Beginning with the Middle Ages, which saw the horrors of the Black Death, and also the beginnings of anatomy and physiology, the author goes on to describe the medical and the humanitarian contributions of the eighteenth century, and the effects upon public health of the industrial revolution, political and social reform, and the growth of State intervention in the field of public health as in other fields. The present position of the State medical service in relation to infant and maternal mortality, the health of the school child, the health insurance services, and the international health

services is then dealt with. Finally the author asks: What are the gains and the losses in national health? Some of the gains are obvious, but there are failures and losses also: failure to get ignorant people to recognise quackery, and loss in average fitness through success in saving feeble infants of the type that used to contribute to the infant mortality rate. Here, as the author implies, we come upon a problem which has its moral as well as its medical aspect.

*Common Pests: how to Control some of the Pests that affect Man's Health, Happiness and Welfare* By Rennie W. Doane. Pp viii + 397. (Springfield, Ill., and Baltimore, Md.: Charles C. Thomas, London: Baillière, Tindall and Cox, 1931.) 21s net.

THIS book sets out to be a handy manual for the farmer, stockman, gardener, and the householder. Being intended for American readers, it deals exclusively with American pests, and much of the information given is of little value to readers outside the United States. It contains many Americanisms, and descends at times to a childishness which is extremely irritating. Little is left to the intelligence of the reader, for example, on p. 119, the author, referring to the use of hydrocyanic acid gas, remarks: "As this gas is deadly to all animal life, rats, mice, and all kinds of insects will be destroyed. Any cats, birds, or other household pets left in the house while the fumigating is being done will, of course, suffer the same fate."

The field which the author has attempted to cover is too large to admit of satisfactory treatment, and the ambitiousness of the project defeats its own ends. Spiders, mites, insects, parasitic worms, birds, and mammals are all included. In many cases the descriptions are too meagre to be of use to any but the specialist, and much of the matter is unintelligible to any but the scientific reader. Nevertheless, a vast amount of interesting information is given, much of it very useful to those for whom it is intended, particularly in the chapters on insecticides and the control of insect pests. The matter is well arranged and convenient for reference, and the book is profusely illustrated.

J. O. C.

*Applied Personnel Administration* By J. E. Walters. Pp ix + 338. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 18s 6d net.

ALL human affairs seem to be in process of reorganisation, notably the industrial situation. The contrast between the inter-relationship of master and man to-day and prior to the year 1832 is marked. Formerly, the employee was normally regarded as a mere producing factor, without human interest to the employer. A pioneer in humanisation was Robert Owen, who not only pointed, but also led, the way on the path of Christian socialism in industrial affairs. Sir Walter Besant's later efforts in the same direction met with a practical response in the People's Palace which Mr. Beaumont established in Mile End,

but this, unfortunately, became side-tracked. The United States, as Mr. J. E. Walters shows in this well-arranged and comprehensive book, has gone steadily forward on lines of industrial progress, and though some may consider that there is an excess of officialdom and of official methods, yet the practical outcome of the movement has been beneficial, not to employees and employers alone, but also to the public at large. It may well be that the swing of the pendulum has been excessive, and that a certain tendency towards over-guidance and over-control has resulted; this may, however, presently swing slightly backward, whereby individual self-dependence will be better established.

P. L. M.

*The History of the Maya from the Earliest Times to the Present Day* By Thomas Gann and J. Eric Thompson. Pp x + 264 (26 plates). (London: Charles Scribner's Sons, 1931.) 8s 6d.

THIS brief history of the Mayas should do much in helping to stimulate interest in the archaeology of Central America. Notwithstanding the fact that one British and several American expeditions are now at work each season on Central American sites, very little interest is taken in the results by the English public. Yet the work of these expeditions is adding rapidly to our knowledge of a remarkable civilisation, of which the problems are as fascinating as they have proved baffling. The authors of this little book have not attempted to discuss controversial matters, nor have they aimed at a detailed description of the sites. They give a historical outline of Maya history as revealed by the most recent discoveries of the earliest and latest dates of occupation of the Maya settlements, and sketch briefly the main features of Maya art, industry, daily life, and religion. The book, in fact, contains in readable form exactly the information which will give the background essential for the appreciation of the character and bearing of the discoveries now being made by scientific exploration.

*Social Organisation and Ceremonial Institutions of the Bomvana* By P. A. W. Cook. Pp xi + 171 + 16 plates. (Cape Town and Johannesburg: Juta and Co., Ltd., n.d.) 10s 6d.

THE Bomvana are a Bantu people of the Transkei who, according to their own tradition, are derived from the Amanguema, a people said to have lived in Natal. It is probable that it was somewhere about the middle of the sixteenth century that they were driven out of Natal and settled among the Pondos, with whom they remained until the beginning of the nineteenth century. It is evident that although all call themselves Bomvana, the tribe is composite. Mr. Cook has made a very thorough study of their social organisation, religion, and ritual. While their institutions generally conform to type, it is indicated very clearly that, speaking broadly, no generalisation about the Bantu peoples of South Africa is sound. Each must be studied individually. This warning is not unnecessary, even for anthropologists, and still less for the administration.

## Young, Champollion, and Hieroglyphics

By Dr ALLAN FERGUSON

IT is a seemly thing to "praise famous men renowned for their power, giving counsel by their understanding . . . who were honoured in their generation, and were the glory of their times", but it is well, even in a centenary notice, to be strictly accurate in assigning priority. Champollion accomplished great and lasting work for Egyptology, but it is not correct to describe him as the man "who first deciphered the hieroglyphics" (NATURE, p 307, Feb 27, 1932). The phrase implies a rounded-off and complete contribution to knowledge such as is seldom made by any pioneer, and was certainly not made by Champollion. He did notable work in the deciphering of hieroglyphics, but he owed much to the labours of at least one of his predecessors, and unfortunately was not at all ready to acknowledge the help which such work had afforded him.

To-day it is not a question for discussion—it is a matter of fact that the first successful steps towards the solution of the problem of hieroglyphics were due to the genius of Thomas Young, and it is demonstrable that Champollion had not realised the correct mode of attack on the problem until Young's discoveries pointed out the way.

Young's is an arresting character—he crowded into his fifty-six years of life (1773–1829) more and more varied discoveries than seems possible for any one man, however greatly gifted. His work in optics, in the theory of surface forces, and in the science of Egyptology is in the first rank. Less important, but illustrating his amazing versatility, are his contributions to medical science and to the theory of the tides, his articles on subjects so diverse as life assurance, bridges, carpentry, and pendular oscillations. His gifts of scholarship are well exhibited in recorded notes of conversations with London scholars—notes which show that, at the age of eighteen, he could argue questions of criticism and emendation, on not unequal terms, with the great Porson himself.

The study of the development of genius is always interesting, and never more so than in the case of Young.\* In spite of the immensity and variety of his learning, the amount of his reading was not very large, but "he adhered strictly through life to the principle of doing nothing by halves. Whatever book he had begun to read, he read completely and deliberately through, whatever study he commenced, he never abandoned, and it was by steadily adhering to this principle . . . that he was accustomed to attribute in after life a great part of his success, both as a scholar and as a man of science."

It is noteworthy that he took small account of any gifts of inspiration of genius, laying weight

rather on concentration and on an accurate knowledge of, and attention to, matters of detail. This last-named power is shown in his exquisite Greek script—calligraphy in the literal sense of the term—and its application as a weapon of research cannot be better exhibited than in his copies of the Rosetta stone inscriptions and in his laborious piecing together of their texts.

The story of the Rosetta stone has not been told so often as to have lost its interest, and in view of Champollion's centenary, may bear retelling.

It was in 1799 that the stone was unearthed by a French engineer engaged in digging the foundations of a fort in the neighbourhood of Rosetta, a small Egyptian town some miles north-east of Alexandria and situated on an arm of the Nile near its mouth. With many other antiquities it was handed over to the English after the capitulation of Alexandria, and was deposited in the British Museum in February 1802. It is a slab of black basalt 11 inches thick, and in surface dimensions is now about 3 feet 9 inches by 2 feet 4½ inches, but it has lost large fragments from the upper corners and from the right-hand bottom corner. In its un mutilated state it was probably 5 or 6 feet high. It carries three inscriptions, written in two languages. The uppermost inscription is written in the sacred character, the middle in the cursive demotic character, and both these inscriptions are in the Egyptian language. The third and lowermost inscription is written in the Greek language and in Greek uncial characters.

It follows from the manner in which the stone has been mutilated that the hieroglyphic text has suffered most. The demotic text contains 32 lines, 14 being imperfect at the beginnings, the Greek text contains 54 lines, 26 being mutilated at the ends, the hieroglyphic text contains some 14 lines, about half of the text having disappeared.

In the year 196 B.C., there was a general assembly of Egyptian priests held at Memphis to commemorate the accession of Ptolemy V. By reason of the benefits that Ptolemy had conferred upon the land—benefits which included gifts to the temples, remission of taxes, the administration of justice, abolition of the press-gang for the navy, and the founding of temples—the priests assembled in council decreed that certain specified additional honours should be paid to him and to his ancestors, and they further ordained that the decree should be inscribed upon "a stele of hard stone in the writing of the words of the gods, and the writing of books, and the writing of the lords of the North, and it shall be made to stand in the sanctuaries in the temples . . . near the statue of the King of the North and South, Ptolemy, living for ever, beloved of Ptah, the God who maketh himself manifest, whose deeds are beautiful."

\* Peacock, "Life of Young", Leitch, "Young's Miscellaneous Works" (3 vols.), E. A. Wallis Budge, "First Steps in Egyptian", E. A. Wallis Budge, "The Decrees of Memphis and Canopus" (3 vols.)

This, then, is the import of the inscriptions on the famous stone

Egyptian writing exists in three forms—hieroglyphic, the sacred picture-writing, hieratic, a simplified form of hieroglyphics, and demotic, an abbreviated form of hieratic writing. We have to remember, in order to realise fully the difficulties that faced the pioneers in this work, that a hieroglyphic symbol may be an ideograph, or may represent a sound, and in the latter case it may represent either a syllable or a letter. The difficulties of elucidation are further emphasised by the existence of determinatives, or signs which help to represent the meanings of words written with the aid of alphabetic or syllabic symbols. Thus, to take a very simple example, the word for *obelisk* (tekhen) may be written by drawing the picture of an obelisk, or, if, however, we write the word by means of the alphabetic symbols t, kh, n, we make assurance doubly sure by following this by a picture of an obelisk, used as a determinative.

The Greek text was early deciphered, and a conjectural restoration of the ends of the mutilated lines was made by Porson. The Oriental scholars, Silvestre de Sacy and Akerblad, worked at the demotic text with some small measure of success, but the first seriously successful attack on the Egyptian inscriptions was made by Young. So early as 1814, Young had made translations of these texts, and in his "Account of some recent Discoveries in Hieroglyphical Literature and Egyptian Antiquities", published in 1823, he enumerates some nine of his early deductions—that simple objects are represented by their actual delineations, and that many signs are used in a figurative sense, he gives the signs for the dual and the plural, for units and for tens, the rule for the direction in which hieroglyphics must be read, remarks that the name of Ptolemy alone existed on the Rosetta stone, and that proper names are included in an oval ring.

This account of his early work was published in 1823 and, in a disputed question of priority, needs careful and critical comparison with the earlier dated publications, we have now, however, to chronicle the publication of a work which, without the slightest possibility of cavil, establishes Young's priority in this region of research. This is the article on "Egypt", originally published in 1819 in the supplement to the "Encyclopædia Britannica". In the plates which accompany this article he prints a word list, and, most important of all, gives a list of alphabetic and syllabic characters. Out of thirteen signs, six are correct, three partly correct, and four wrong. This article, as Sir E. A. Wallis Budge remarks, "is practically the foundation of the science of Egyptology, because it contains a list of a number of alphabetical Egyptian characters to which, in most cases, he had assigned correct value. In other words, the idea of a phonetic principle in the reading of hieroglyphics, which had been but dimly comprehended by Warburton, De Guignes, Barthélemy, and Zoega, was clearly grasped by Dr. Young, and was accurately applied by him FOR THE FIRST TIME in the history of the decipher-

ment of the Egyptian hieroglyphic. As Chabas rightly expressed it, 'Cette idée fut, dans la réalité, le *fiat lux* de la science'."

Now let us briefly consider the claims of Champollion (1790–1832) to be described as the first decipherer of the hieroglyphics. Devoted as he was to classical and Oriental studies from an early age, he accumulated a mass of knowledge which, in this field, far surpassed that of Young. In 1812 he was appointed professor of ancient history at Grenoble, and in 1821 he published his treatise, "De l'écriture hiératique des anciens Égyptiens". In the course of this work he states unambiguously that hieratic writing is not alphabetic, that it is a simple modification of the hieroglyphic system, differing therefrom merely in the form of the signs, that it must be considered as hieroglyphic tachygraphy, and that *hieratic characters are signs of things and not signs of sounds*.

It is obvious, therefore, that despite Young's publication of 1819, Champollion, in 1821, was convinced that there was no trace of an alphabet in the hieroglyphic and hieratic characters. In 1822 all is changed. Champollion now publishes his famous "Lettre à M. Dacier, relative à l'alphabet des hiéroglyphes phonétiques employés par les Égyptiens pour inscrire sur leurs monuments les titres, les noms et les surnoms des souverains grecs et romains", in which the alphabetic character of many of the symbols is clearly defined and an alphabet published. As we have seen, Young had already published an alphabet based on an analysis of the names Ptolemy and Berenice. Moreover, it should be noted that Bankes had identified *as a whole* the set of signs which make up the name of Cleopatra. With the letters obtained from Ptolemy and Berenice as a guide, it becomes a matter of cryptogram analysis to find the meaning of the unidentified symbols in the signature of Cleopatra, and with every further extension to a new name the process becomes more easy and more certain.

What is to be assigned as the cause of the remarkable change in the opinions of Champollion? Peacock states categorically that Champollion endeavoured to suppress his unfortunately expressed work of 1821, it is certain that he sent the illustrations of the work to Young without the letterpress—a method admirably adapted to obscure the date of publication—and it is difficult to give any reason, at all creditable to Champollion, for his persistent misstatements concerning the relation of Young's researches to his own.

The probability is that Champollion, who must, before 1821, have become acquainted with Young's Egypt article of 1819, had not appreciated its full significance, more especially as some of its results are stated by Young in a characteristically diffident fashion. If we assume that Champollion realised the full meaning of Young's great advance only after he had published his work of 1821, the matter seems tolerably clear.

However this may be, it is certain that Champollion's contributions to the elucidation of hieroglyphics, great as they were, and carried as they

were to a point which Young could never hope to reach, were posterior to, and probably determined by, Young's fundamental contribution

"In a lapidary inscription a man is not upon oath," said Johnson. That is very true, and the great mass of such inscriptions may be permitted an affectionate exaggeration of the qualities of the departed. But when we read on the tablet in-

scribed to Young's memory in Westminster Abbey a eulogium of Young as one who "alike eminent in almost every department of human learning, patient of unintermitted labour, endowed with the faculty of intuitive perception" first penetrated the obscurity which had veiled for ages the Hieroglyphics of Egypt", we are reading no more than the literal and unadorned truth

### Oil and Petrol from Coal\*

By Prof C. H. LANDER, CBE

ALL fuels consist essentially of carbon and hydrogen combined in different proportions. In oil, the proportion of hydrogen to carbon is higher than in coal; further, oil contains less oxygen than coal. It is thus obvious that in order to turn coal into oil the proportions of carbon, hydrogen, and oxygen must be suitably readjusted. Various ways of doing this have suggested themselves to the scientific mind, but oil was first produced commercially from coal almost, as it were, accidentally, for it is one of the by-products in the manufacture of gas from coal.

Gas is made by the destructive distillation of coal, usually termed carbonisation. In this process, the coal is heated to a high temperature in closed retorts, the gas and condensable vapours which are driven off are collected, and from the resulting liquid products a certain quantity of oil can be prepared. In the course of these reactions there is a redistribution of the carbon and hydrogen atoms, the coke, which is left behind in the retort, consists mainly of carbon, and has a lower proportion of hydrogen than the original coal, while the liquid and gaseous products have a higher proportion of hydrogen than the original coal.

If the carbonisation is carried out at a lower temperature, say at a dull red heat instead of the bright white heat associated with normal gas-making processes, the yield of gas is less and the yields of coke and liquid products greater, while the latter are more nearly akin to natural petroleum. This process is usually known as low-temperature carbonisation.

Since light spirit is at the present time far more valuable than heavy oils, there have been introduced methods of again redistributing the molecules in the liquid products from the carbonisation of coal, so as to obtain higher yields of the lighter spirit. During this process, which is known as cracking, a residue, which has been deprived of hydrogen, appears as coke. Cracking is also widely applied to the heavier fractions obtained in the distillation of petrol from natural oils.

In obtaining petrol directly from the carbonisation of coal, low temperature carbonisation, cracking pushed to its limits, and the scrubbing of the gas to recover further small quantities of light spirit have not up to the present been able to raise

the total yield of motor spirit beyond 6-7 gallons per ton of raw coal. It must, however, not be forgotten that the primary object of carbonisation processes is the manufacture of coke and gas, and that light spirit, valuable as it may be per gallon, is still only a by-product.

The enormous importance of oil and petrol in modern civilisation has naturally focused attention on the possibilities of reshuffling the molecules in the coal in a way favourable to greater oil production, but, as I have already pointed out, coal, as compared with oil, is deficient in hydrogen. The possibility therefore suggests itself of adding extra

FIG 1

hydrogen to the coal substance in order to make up this deficiency, and then, by some means or other, inducing the molecules of the mixture to reshuffle themselves into oil molecules. This has actually been accomplished, and for this success due credit must be paid to the work of Dr Friedrich Bergius, at Mannheim, who was the first to liquefy coal by direct hydrogenation.

Important and striking developments of the hydrogenation process as applied to coal have been made during the past six years, in Great Britain mainly by the Fuel Research Board and Imperial Chemical Industries, Ltd. Fig 1 † shows how the oxygen, nitrogen, and sulphur in the coal are removed as water, ammonia, and sulphuretted hydrogen. The residual hydrocarbons in the coal (95 per cent C, 5 per cent H) break down and combine with hydrogen to give a large percentage of petrol (88 per cent C, 12 per cent H), the solid material probably passing through heavy oil (93 per cent C, 7 per cent H) and middle oil (91 per cent C, 9 per cent H). It will be seen that although at present

\* From the Friday evening discourse at the Royal Institution delivered on Nov 20, 1931.

† For this and the other illustrations selected from the original discourse for publication here, thanks are due to Imperial Chemical Industries, Ltd.

petrol forms the most attractive product on account of its comparatively high price, the process could be stopped at an intermediate stage and so made to yield kerosene, diesel oil, or fuel oil

So important to the interests of Great Britain did the possibilities of the hydrogenation of coal appear that active work was inaugurated at the Fuel Research Station in 1922, with results so encouraging that in 1926 an intermediate-scale continuous plant, on the lines of Bergius' latest development, was set up at the Fuel Research Station, and, largely through the foresight of Dr W. R. Ormandy, who had organised a syndicate to explore the possibility of applying the Bergius process to British coal, an agreement was entered into between the British Government and Dr Bergius for the pooling and mutual discussion of the results obtained in both laboratories

#### BERGIUS PROCESS

The Bergius process consists essentially in subjecting coal to the action of hydrogen at a high temperature and a high pressure. The powdered coal is prepared for treatment by mixing it with a small quantity of alkaline iron oxide (luxmasse), which acts as a catalyst, and a suitable oil or tar, which may be a fraction of the liquid product obtained from previous runs

For the preliminary exploration of the process on a small scale, converters consisting of steel-walled vessels, closed by means of a blank flange, and of capacity about 2 litres, are used. A spindle projects from each end of the closed converter so that it can be carried on bearings and rotated over a row of gas flames. The pressure is measured by means of a gauge attached to one of the spindles through which there is drilled a passage to the interior of the vessel, and the temperature is measured by a thermocouple contained within a closed tube carried by the cover and projecting into the converter along its axis

In hydrogenating coal by the original Bergius process, a thoroughly well-mixed paste is made from 20 parts of coal, 1 part of iron oxide (luxmasse), and 8 parts of oil, the oil being taken from some of the heavier fractions obtained from previous runs. This paste is inserted into the converter, which is then closed. Hydrogen is pumped into the converter until a pressure of about 100 atm is reached, when the converter is placed in its bearings and rotated over the gas flames, the temperature being raised to about 450° C, while the pressure at the same time rises to about 200 atm. The reaction is allowed to proceed for two hours, after which the converter is cooled and the products extracted

In these discontinuous experiments it is possible to use coal either in the dry powdered state or in a paste. In a continuous plant, however, there would be great difficulty in injecting a solid material in powdered form into an enclosure which is already under a high gaseous (hydrogen) pressure. By mixing the fine coal with oil into a paste a material is obtained which can be pumped, and this

expedient formed one of the most important claims in the Bergius patents

In the small continuous Bergius plant, capable of dealing with about one ton a day, installed at the Fuel Research Station, the product is a relatively mobile oil, and the rough balance-sheet of the process shows that 50 per cent of the coal is transformed into distillable oil, 20 per cent into gas, and about 15 per cent remains as partially converted material. Some of the partially converted solids remain in suspension in a very fine state in the crude hydrogenated product, and make it very difficult to distil, but by taking proper precautions a series of fractions can be obtained. The heavier fractions can be rehydrogenated for the production of a further quantity of light spirit

#### FUEL RESEARCH STATION MODIFIED PROCESS

Further experimental work was carried out at the Fuel Research Station in order to increase the yield of the lighter fractions at the expense of the heavier oils, and to examine the process in the absence of a complicating factor such as a liquid vehicle for converting the coal into a paste. Improved catalysts were used, and the work was carried out in two stages. In the first stage, coal mixed with a suitable catalyst was heated under pressure in a stream of hydrogen. The reaction products were carried over by the hydrogen and through a second catalyst, in which further conversion to motor spirit took place in the gaseous phase. Experiments have been carried out using 50 lb of clean coal, and a yield of 140 gal of motor spirit was obtained per ton of dry, ash-free coal. The net hydrogen required amounted to 8.8 per cent by weight of the coal, giving, together with the 5.6 per cent already present, a total of 14.4 per cent of hydrogen required for the reactions

The yields of the different products obtained in the processes of high and low temperature carbonisation and a hydrogenation process are shown in the accompanying table

YIELDS FROM BITUMINOUS COALS SUBMITTED TO DIFFERENT TREATMENTS

|                                     | Carbonisation    |                 | Hydrogenation (Fuel Research Station) |

(To be continued)

### York Meeting of the British Association

THE British Association, after celebrating its centenary in London last year, will return this year appropriately to its birthplace, York. The annual meeting will be held there on Aug 31–Sept 7, and the preliminary programme has just been issued. The reception room will be in the Exhibition Buildings. The inaugural meeting and evening lectures will be given in the adjoining exhibition hall, a structure which, when it served the same purpose for Ramsay, Huxley, and Spottiswoode at the jubilee meeting in 1881, was labelled as ‘temporary’, but through various vicissitudes has stood the test of time, and now has been amply restored since its service as a post-office sorting-shed.

Under the new arrangement of the period of the presidency, Sir Alfred Ewing has already assumed that office for the present year, and the subject of his presidential address is now announced as “An Engineer’s Outlook”. Many other topics of wide interest are already set down for addresses, lectures, or discussions—some of them are even intriguing. Thus a pleasing anticipation cannot but supervene when, reading on from the title of the presidential address, the eye is held by that of Prof Miles Walker’s address to Section G (Engineering)—“The Call to the Engineer to Manage the World”. Again, those who have wisely fostered co-operation between the sections should be no less satisfied than interested by the announcement of a joint meeting between Sections A (Mathematical and Physical Sciences) and J (Psychology) to discuss the quantitative relation of physical stimuli and sensory events.

Among the sectional presidents, Prof A O Rankine’s address to Section A will deal with physics in prospecting for minerals. Stereo-chemistry will be an important topic in Section B (Chemistry), as the presidential address by Dr W H Mills will deal with it, and it will also be the subject of a discussion. Prof P G H Boswell, undertaking an onerous double duty in presiding over Section C (Geology) while also a general secretary of the Association, will give his address on “The Contacts of Geology: The Ice Age and Man”, and this section also announces a joint discussion with Section H (Anthropology) on geology and prehistoric archaeology. Primates and early man will be considered by Sections D (Zoology) and H (Anthropology). The subject of Lord Rothschild’s address to Section D is not yet announced. Prof H J Fleure will address Section E (Geography) on the geographical study of society and world problems, Prof R B Forrester, Section F (Economics), on Britain’s access to overseas markets, Dr Randall MacIver, Section H (Anthropology) on the place of archaeology as a science, Prof Beatrice Edgell, Section J (Psychology) on current constructive theories in psychology, and Prof J H Priestley, Section K (Botany), on “The Growing Tree”. The department of forestry under

the last section will hear an address from Mr T B Ponsonby on a system of forestry for the British Isles. The Association, through the work of committees and otherwise, has long striven to foster the advancement of science in schools. This will be the subject of Mr W M Heller’s address to Section I (Education), and, it is understood, may be also discussed at a special evening meeting. Prof R G White’s address to Section M (Agriculture) will deal with sheep farming. It may be added here that Section I (Physiology) will not meet in view of the simultaneous meeting of the International Physiological Congress in Rome.

Among other subjects, the interests of York, Yorkshire, and north-eastern England will rightly find a prominent place. The chemists will discuss water pollution with special reference to the present investigations in the River Tees. The relation of the millstone grit to the carboniferous limestone, the gravels of the Wolds margin, and the concealed coalfield of East Yorkshire appear in the geological programme. Section E announces a series of communications on local physical, historical, and industrial geography, and Roman archaeology will appropriately receive close consideration in Section H. The university movement and adult education in Yorkshire will be discussed in the educational section. Lastly, in so important a railway centre as York, the home also of a railway museum (which will be visited), it is fitting that Section G (Engineering) will consider railway traction by steam, oil engine, and electric power.

Evening discourses will be given by Sir Arthur Hill on plant products of the British Empire in relation to human needs, and by Mr C C Paterson on uses of the photoelectric cell, while Mr H E Wimperis will give an afternoon lecture, not for members exclusively, on high speed flying.

An evening reception will be given by the Lord Mayor of York (Alderman Vernon Wragge) and the Sheriff (Mr Arnold Rowntree). Many points of interest in the neighbourhood of York (and none is richer in them) will be visited. The Yorkshire Philosophical Society, mother society of the Association, will welcome its well-grown daughter by throwing open its museum and gardens to members daily throughout the meeting. The museum itself, scene of the first meeting of the Association in 1831, and headquarters of its organisation under John Phillips, will now house Section D (Zoology) in its more modern Tempest Anderson hall.

Local officers and a committee in York already have the local arrangements fully in hand, including the important question of housing visitors. In this connexion, it is impossible to resist a quotation from the announcement of the first meeting, in 1831. Therein it was provided that on the first day of the meeting “the Managing Committee will receive, at the Museum, the names of Persons intending to be present, and will deliver tickets for the Morning and Evening Meetings, and Dinners, and references

for Lodgings The Committee will think it right to pay regard to economy, as well as convenience, in these arrangements" Without doubt the present local committee shares this aspiration, but members will not fail to take cognisance of a footnote to the above announcement, which appears in the

Report for 1831 "On Tuesday a public dinner was provided at Twelve Shillings a Ticket, on the other days, during the session, ordinaries at from Five to Seven Shillings a head venison, game, and fruit being contributed" In this respect at least there need be no fear that history will repeat itself

### Obituary

M GUILLAUME BIGOURDAN

THE death of M Bigourdan has taken from us a veteran astronomer, well known to many of his English colleagues He attended the meeting of the Paris Academy of Sciences on Feb 22, in his usual health, but died suddenly on Feb 28 Born at Sistels (Tarn-et-Garonne) on April 6, 1851, M Bigourdan graduated in the École d'Astronomie in Paris, and was in 1877 appointed by M Tisserand as an assistant in the Observatory at Toulouse Here he was employed on meridian astronomy and devoted his leisure to historical studies in astronomy, which interested him all his life

In 1879, M Bigourdan was appointed assistant at the Paris Observatory and had charge of the large equatorial Here he spent many years in the most assiduous observations of the positions of nebulae and clusters In this very trying work he determined the positions of the known nebulae with all the precision possible from visual observations, discovered many new ones, and incidentally made measures of comets and double stars The intention underlying these arduous observations was to provide such accurate positions of the nebulae that future astronomers might detect small movements in these very distant objects The results were published in the *Annales* of the Paris Observatory, and have since been collected in five large volumes, consisting of about three thousand pages The gold medal of the Royal Astronomical Society was awarded to M Bigourdan in 1919 for this monumental work

Owing to differences between French and English observers in the values for the longitude of Paris, a re-determination was made in 1902 by M Bigourdan and M Lancelin working simultaneously with Sir Frank Dyson and Mr Hollis The results were in satisfactory accordance, and the mean differs by only 0.01<sup>s</sup> from the recent

determination made by 'wireless' transmission of time-signals M Bigourdan was from its commencement interested in the transmission of time by wireless, which is due to so great an extent to the initiative of General Ferrié When Paris became the centre of the international time service, he was, until 1928, director of the Bureau

In 1882, M Bigourdan took part in the observations of the transit of Venus in Martinique, and he was a member of eclipse expeditions to Senegal in 1892, to Spain in 1900, and to Tunis in 1905 He was for many years a member of the Bureau des Longitudes, and enriched many volumes of the *Annuaire* by articles on astronomical topics His most important work on the history of astronomy was the bringing out of the "*Annales célestes du dix-septième siècle*" by A G Pingré This work was completed in manuscript in 1791 and a beginning made of its publication This went on slowly until the death of Pingré and then ceased The manuscript was lost, but was found by M Bigourdan under a wrong designation in the Paris Observatory It was printed in 1901 under the auspices of the Academy of Sciences

M Bigourdan was courteous and affable, and always put his point of view with vigour and vivacity An incident which took place at the meeting of the International Astronomical Union at Rome in 1922 may be recalled The discussion was bilingual One of the British delegates spoke in French, which his British colleagues all understood Whether M Bigourdan had not been listening, or whether he wished maliciously to indicate that the French was not perfect, I do not know, but he amused his British colleagues by calling out "Traduction"

He married a daughter of Admiral Mouchez, and they had nine children, to whom we would offer our respectful sympathy F W DYSON.

### News and Views

#### Oliver Heaviside's Work

At a meeting of the Institution of Electrical Engineers on April 21, Dr W E Sumpner gave the annual Kelvin Lecture, choosing as his subject the work of Oliver Heaviside Before the lecture, the Faraday medal, the highest honour the Institution can give, was presented to Sir Oliver Lodge Dr Sumpner said that the work of Heaviside blended telegraphy, the earliest activity of electrical engineers, with radio communication, their latest activity The older electricians were in the habit of applying Kelvin's formulæ, which apply only to submarine cables, to telephony Heaviside's idea of increasing the self-

induction of the line was diametrically opposed to the prevailing practice The whole industry was in the hands of a government department very properly reluctant to try expensive experiments Heaviside's mathematics were not easy to understand and wanted laborious study even by professed mathematicians This was why some of his theories, although suggested several years before they were practically tried in France and America, were never actually put to the test in Great Britain His 'distortionless' circuit enabled signals to be transmitted at high speed in submarine cables and made telephony through long cables possible His work on the cable problem did

a great deal more than lead to the theory of the 'loading coil'. It showed that ordinary telegraphy was only a special form of directed wave telegraphy. Heaviside was the first radio-telegraphist. His analysis of Maxwell's theory was of the orthodox type, but when he dealt with the cable problem, he threw over all the conventional methods used by mathematicians.

#### The Mellon Institute at Pittsburgh

THE nineteenth Annual Report of the director, Dr E R Weidlen, to the trustees of Mellon Institute of Industrial Research, Pittsburgh, Pa., with which the name of Mr Andrew Mellon, the new U S Ambassador in London, is associated, has recently been issued. It appears that the sum of 722,541 dollars was received by the institution from industrial fellowship donors during the fiscal year ended Feb 29, 1932, bringing the total for the past 21 years to 8,277,018 dollars. Throughout the past year 75 industrial fellowships, employing 176 scientific workers and engineers, were in operation. At the close of the year, 58 fellowships were active, and of these, 28 have been at work for five years or longer and 13 have concluded more than ten years of research. Since 1911, when the industrial fellowship system was established at the University of Pittsburgh, Mellon Institute has had fellowships on 230 distinct subjects, on which 775 workers have been engaged, and 313 fellows and 357 fellowship assistants, having completed their services, have entered the fields of industry and education. As trained additions to the forces of manufacturing and teaching, these men constitute the Institute's greatest contribution to humanity. The constructional work on the Institute's new building is proceeding satisfactorily, it is thought that this edifice will be completed and ready for occupancy in the summer of 1933.

#### Testing Work for the Building Industry

IN recent years there has been a growing demand on the Building Research Station of the Department of Scientific and Industrial Research for tests and reports on building materials and forms of construction. In order to enable the Station to cope with these requests, a panel of approved testing laboratories is being established to act in association with the Station. The essence of the scheme is to put the Station in the position to have tests carried out at laboratories on the panel and then to incorporate the results in Government reports or certificates issued by the Station. The bulk of the tests will probably be mechanical or physical, of the chemical tests, most will probably be simple analyses. Applications are invited from testing laboratories wishing to participate in the scheme. Further particulars and forms of application can be obtained from the Director, Building Research Station, Garston, Herts.

#### Building Research

WE have received the Report of the Building Research Board for the year 1930 (London H M Stationery Office 2s 6d net), which is a document of 136 pages with an index. The report deals with a

number of important aspects of building materials and construction. In a section on damp walls it is pointed out that it does not seem possible to guarantee that a solid brick or masonry wall will exclude damp under all conditions, but no instance has been recorded of the failure of a properly constructed cavity wall to exclude damp. Experiments on noise in buildings showed that where the weight of material necessary to obtain sound insulation is excessive, a considerable reduction of noise can be obtained by the use of composite structures with air spaces between the component parts. The efflorescences on brickwork, due to soluble salts in the bricks, mortar, or external sources, are best removed by washing by hand when the amount of soluble salts is limited. The preparation of standard specifications for building materials is receiving special attention by the Board in conjunction with the British Standards Institution, and it is highly satisfactory to note that a considerable measure of co-operation between the Building Research Station and industry has been achieved. The report also refers to a considerable amount of work on concrete and reinforced concrete which has been carried out, and a new laboratory is being erected to house this work. The report shows that a very useful purpose is being fulfilled by the Board, the activities of which may be expected to increase in several directions as time goes on.

#### Agricultural Parasites Research in Canada

INTERNAL parasites are one of the stock-farmer's biggest problems all over the British Empire. They are the poultry-farmer's worst enemy, and, in all probability, constitute the most severe check on the growth of the poultry industry in the British Isles. In Canada it has been estimated that parasitic infestation causes an annual loss of £4,000,000 and is responsible for the death of one-tenth of the Dominion's live stock. A new Empire centre for the scientific study of internal parasites has been established in Canada, with the assistance of a grant from the Empire Marketing Board. New buildings, which will house the Institute of Parasitology, are now being erected by the Quebec Government at Macdonald College, the agricultural college attached to McGill University. The scheme is being financed for three years jointly by the Empire Marketing Board and the National Research Council of Canada. It marks the first occasion on which the Canadian Government and the Empire Marketing Board have combined to support a joint scheme of research. It is hoped that the new Institute may eventually become an Empire headquarters for the study of internal parasites, somewhat as Onderstepoort, in South Africa, has become recognised as an Empire centre for animal diseases research. The scheme therefore provides a fresh example of Empire team-work in the field of agricultural research.

#### Change-Over from Direct to Alternating Current

AT the present time electricians are interested in the problem of the change-over from direct current to alternating current systems of supply. Where new systems are being laid down in Great Britain the

three-phase, four-wire alternating current system of supply is being taken as the standard, the pressure of supply from the three outers to the neutral main being 230 volts. There is still a large number of supply stations in Great Britain which do not use the standard system, and if they are to reap the benefits of standardisation they must change to a c. In a paper by H. Blades and A. C. MacQueen, read to the Institution of Electrical Engineers on March 31, this change-over is discussed. They show that the problems arising in dealing with small towns and suburban and residential districts are different from those arising in industrial and city areas. In the former areas the change-over from d c systems to a c systems should take place at the earliest possible opportunity. As the life of a c low pressure cables is, as a rule, about twice as long as that of d c cables, the costs for renewals would be considerably diminished. Some eight years ago a supply undertaking replaced a large section of its direct current network with very satisfactory results. The total cost of the change-over was cheaper than the estimated cost of replacing the old d c system and the maintenance and development charges were appreciably reduced. The faults which frequently occurred in the mains when direct current was used now practically never occur. The best methods of carrying out the change-over are given in the paper, and the necessary arrangements that have to be made with the consumers explained. As the number of consumers who have radio receivers actuated from the mains is rapidly increasing, the change-over costs to the supply companies increases concurrently, and this in addition to the engineering and technical reasons makes an early change from d c to a c advisable. In industrial and city areas the best rate at which the change-over should occur depends on the demand and the condition of the direct current plant.

#### Clocks Worked from the Electric Supply Mains

WHEN a house is supplied with alternating current electricity on the time-controlled system, it is possible to use an electric clock which keeps almost exact Greenwich time, the error being at the most only a few seconds per week. The principle used in their working is that of the synchronous motor, which keeps in exact step with the frequency of the alternating current, and the frequency is controlled by a 'master controller' regulated by Greenwich time so as to make it easy to synchronise the generators connected with the network. The clocks cost from thirty shillings upwards, depending on the size and design of the case used. The first synchronous clocks were used in the United States about twelve years ago, and, from their inventor, were called Warren clocks. In America more than six million have been sold and in Great Britain about a quarter of a million (*Electrical Industries*, March 16). They are made of two types. In one class the clock is self-starting and in the other it has to be started if the current stops even for a fraction of a second. In the latter class a red disc usually appears on the rare occasions when it stops. The clocks require only about half the power taken by an ordinary electric meter, and

so the cost of running them is only a few pence a year. In America the sales are usually made by the electric supply companies, but in Great Britain the dealers who sell electric accessories and the clock-makers have taken up their sale. As a rule, the clocks require no attention for many months. In districts supplied by suitable alternating current, it is probable that this type of clock will supersede the escapement and pendulum type. Electric movements can be obtained to replace the ordinary clockwork movement of an existing clock.

#### The *Akron*, the Airship of the United States Navy

IN the new airship *Akron* built for the United States Navy there are incorporated several improvements which set new standards of efficiency for subsequent lighter-than-air machines. The ship is larger than most ocean liners and, unlike most of its predecessors, it is largely actuated by electricity and electrical apparatus. Particulars of the ship are given in the *Westinghouse International* for the first quarter of 1932. The power plant consists of two petrol-driven 11-kilowatt generators, with a motor generator set for battery charging. The total weight allowed for the electrical system on board was only 3000 lb. Aluminium alloys were largely used for the machines and cables, and all the circuits are controlled from the generator room. The radio system takes the heaviest load from the generators. The antenna system consists of two trailing antennae and a fixed wire antenna. The latter is used for landing manoeuvres and for auxiliary purposes. Fire risk is practically eliminated, the twelve supporting gasbags of the ship being filled with helium, but even if they had been filled with hydrogen there would have been little risk of explosion, as every power outlet on the ship is so constructed that the plug cannot be removed or inserted unless its switch is in the 'off' position. Miniature lightning arresters protect the ship from static charges of electricity picked up while the ship is in flight, especially when she changes from one equipotential surface of the earth's electric field to the other. These arresters also drain off any electrostatic charges that might be induced by the ship's radio. The telephone system has seventeen telephones, the switchboard on which the keys and lamps are mounted weighing only thirty pounds. A special feature of the *Akron* is the powerful searchlight which is used for signalling and for landing. It consists of a 500-watt lamp with a fourteen-inch reflector. In daylight tests its light is brilliantly visible at a distance of four miles.

#### Recent Acquisitions at the Natural History Museum

THE Zoological Department of the Museum has secured a mounted example of an exceedingly rare marsupial mouse, *Canolestes obscurus*, from Mount Pichincha, Quito, Ecuador. This species belongs to that group of marsupials which, from the possession of only two incisor teeth in the lower jaw, is known as the Diprotodontia. Except for this solitary species, found in a restricted area of the high Alpine country of the Central Andes in Venezuela, Colombia, Ecuador, and Peru, the diprotodont marsupials are found only in the Australian region. The Department of

Entomology has acquired the important collection of British Coleoptera (beetles) formed by the late Dr David Sharp, who died in 1922. The collection comprises nearly 114,000 specimens, most of which were collected by Dr Sharp himself. Dr Sharp's general collection of Coleoptera, consisting of at least 300,000 specimens from all parts of the world, was purchased by the Museum in 1905. More than 4000 additional foreign specimens have been received with the British collection. The Trustees have approved the purchase for the Department of Geology of a collection of Nothosaurs from the Alpine Trias of Besano. These small swimming reptiles were precursors of the better known Plesiosaurs. The specimens acquired appear to belong to two species of the genus *Pachypleurosaurus*. There has been placed on exhibition in the Department of Geology, near the entrance, the first of a contemplated series of scenes representing the fish-fauna of succeeding geological epochs. It shows reconstruction-models of fish-like animals and true fishes that lived just when the Silurian was passing into the Devonian period. They are the earliest 'back-boned' animals of which fossil remains have been found. The models are posed in an illuminated scene, the surface of the underwater scene being just below the eye of a spectator of average height, at the eye-level, the distant hills of the Old Red Sandstone period are seen.

#### Minerals at the Natural History Museum

IN 1930 the experiment was tried of issuing a free guide-leaflet to the exhibition collections in the Mineral Department of the Natural History Museum at South Kensington. The distribution of the leaflet is helped by some attractive exhibits of popular interest placed near the entrance to the gallery. By these means a considerably larger number of visitors have been induced to take an intelligent interest in the collections. The fact that 20,000 of these leaflets have been taken away by visitors, none being left as litter, proves that they have been appreciated. In the four-page leaflet, attention is especially directed to the various uses of minerals by giving lists of gemstones, ores of the metals, other minerals of economic importance, building and road stones, ornamental stones, and radium-bearing minerals, with the number of the cases in which each may be seen. A third issue of 10,000 copies of the leaflet is now available.

#### Fellowships for Medical Research

THE Rockefeller Medical Fellowships and the Dorothy Temple Cross Research Fellowships in Tuberculosis for the academic year 1932-33 will shortly be awarded by the Medical Research Council, and applications for either should be lodged with the Council not later than June 1. The Rockefeller Fellowships are provided from a fund with which the Medical Research Council have been entrusted by the Rockefeller Foundation, and are awarded to graduates who have had some training in research work in the primary sciences of medicine, or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching

or research in the British Isles. A fellowship held in America will have the value of not less than £350 a year. The Dorothy Temple Cross Research Fellowships give special opportunities for study and research to persons "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." Candidates must be British subjects and must possess suitable medical, veterinary, or scientific qualifications. The fellowships will preferably be awarded to candidates who wish to make their studies or inquiries outside Great Britain, and are of the value of not less than £350 a year. It may also be possible to award a senior fellowship of considerably greater value to a specially well qualified candidate wishing to undertake an intensive study of some particular problem of tuberculosis at a chosen centre of work in another country. Particulars of these fellowships are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1.

#### International Congress for Anthropology and Ethnology]

THE proposal for the constitution of an international congress for anthropology and ethnology, which was put forward by the Royal Anthropological Institute, has elicited some interesting expressions of opinion from continental anthropologists. Two communications which have been received by the Council are published in *Man* for April. Dr Fritz Krause, of Leipzig, president of the Gesellschaft für Völkerkunde, has been in communication with a number of ethnologists in Austria, Sweden, Holland, and Denmark, and has found that nearly all of them would prefer a congress covering ethnology only. Dr Krause himself personally is in favour of a congress of 'ethnic sciences', of which the mainstay and principal field would be ethnology, but with 'adjacent sciences'—ethnic psychology, sociology, etc.—taken into account and permanently recognised. Dr Krause has offered to push his inquiries further, and thus offer the Council of the Institute has cordially accepted. The second communication is from the Very Rev P. W. Schmidt, who concurs in the view that the interests of ethnology will be best served by a separate congress. In fact, he and his colleagues in Vienna consider that there should be separate congresses for ethnology, anthropology, and prehistory. It is felt, however, that a great advantage would be obtained from a periodically recurring joint congress of all three branches of study. A rotation of four meetings at intervals of two years between each, of which the fourth in each series should be a joint meeting of the three studies, is suggested. This has the obvious disadvantage of an inordinately long interval between the independent meetings in each subject.

#### Medieval Sussex

IN attempting to reconstruct the past geography of England, one of the chief difficulties is to bridge the gap between the Domesday Survey of 1086 and the topographical county descriptions of the seventeenth and eighteenth centuries. In a paper in *Geography* for March, Mr R. A. Pelham has indicated

some sources from which data can be obtained for these centuries, and has outlined the use to which they may be put in the county of Sussex. The distribution of various types of building-stone, when a stone was used outside its area of occurrence in the fabric of a church, throws light on means of transport, especially the navigability of rivers, since waterways were the only satisfactory means of moving heavy materials. Evidence of this source can be strengthened by sheriffs' administrative accounts. These do not give the precise route but the distance and the cost of transport. The sheriffs' accounts also give much evidence concerning the distribution of crops, timber, and wool production. Lastly, much valuable information can be obtained from taxation accounts, particularly the lay subsidy of 1327. This gives a guide to the location of the areas of greatest prosperity. Mr Pelham has illustrated his paper with maps of various aspects of the fourteenth century geography of Sussex.

#### Ice in Arctic Seas

THE Danish Meteorological Institute has published its report on the ice in arctic seas in 1930 (*Isforholdene i de Arktiske Have*). There appears to have been a repetition of the unusual conditions marked by the lack of ice in many seas in 1930. In Spitsbergen the fjord ice was late in forming and relatively thin, and so early as April the western part of the north coast had open water, and by June there was access to the north-east. During July and August the waters of the archipelago were almost free from ice. In the Barents Sea the edge of the ice was unusually far north throughout the summer, and in August a great deal of Franz Josef Land was accessible in open water, which is not usual. The Kara Sea had scattered ice in July but was almost entirely clear in August. So late as November there was little ice in the White Sea. In the east coast of Greenland conditions were less abnormal, but from August until November there was little or no ice off Angmagssalik. The coasts of Iceland were free from ice throughout the year, and south-west Greenland had less ice than usual. Hudson Strait was clear of ice about a month earlier than usual and, except for icebergs, was still free in October. From Siberian waters there were few reports. On the north coast of Alaska the ice lay closely packed throughout the summer. The report is illustrated with the usual charts for each of the spring and summer months.

#### Abstracts of Meteorological Literature

THE *Meteorological Magazine* for March 1932 contains particulars of a collection of abstracts of meteorological literature which has been undertaken by the Meteorological Office, Air Ministry. The abstracts are being gathered from various sources, including authors' own summaries, translated into English where necessary, and a number of meteorologists have volunteered their assistance in summarising papers for which no abstracts are otherwise available. The collection already numbers about a thousand, covering a period of nearly ten years, and it is hoped to include every important paper published in future. The abstracts are being classified according to subject,

the classification adopted being that of the International Catalogue of Scientific Literature, which is also employed in the Royal Meteorological Society's Bibliography, the new collection of abstracts will thus form a very useful complement to the latter. The abstracts will not be published, but will be kept in the Meteorological Office Library for reference.

#### Bibliography of Seismology

THE study of earthquakes and of the transmission of earthquake waves through the earth has lately made such rapid advances that any attempt to enumerate the memoirs published is welcome. We have received from the Dominion Observatory at Ottawa, which is now solely responsible for its publication, copies of recent issues of the *Bibliography of Seismology*, edited by Mr E. A. Hodgson. The number for July-Sept. 1931 contains the titles, with occasional brief abstracts, of a hundred papers. Most countries in which earthquakes are studied are represented, though somewhat unequally, more than one-half of the papers being published in the United States and Great Britain and only two in Italy.

#### British School of Archaeology in Iraq

IT is announced that the subscribers to the fund for establishing a British School of Archaeology in Iraq in memory of the late Miss Gertrude Bell have appointed a council on which the Universities of Oxford, Cambridge, Edinburgh, Durham, and London are represented. In addition, there are representatives of the British Museum, the British Academy, the Royal Geographical Society, the Royal Asiatic Society, the Society of Antiquaries, and other learned societies. The following have been appointed as officers: Sir Percy Cox (president), Sir Edgar Bonham Carter (chairman of the executive committee), Mr E. H. Keeling (hon. secretary), and Brigadier-General Sir Osborne Mance (hon. treasurer). The offices of the School for the present will be at 20 Wilton Street, London, S.W.

#### Scenery Preservation in New Zealand

THE preservation of natural scenery by the institution of reserves is an active policy of the New Zealand Government. The report on scenery preservation of the year ending March 31, 1931, records additional reserves during the year of 131,415 acres, making a total of well over half a million acres. Notable additions include Lake Okareka and surroundings, and some two hundred square miles embracing the Fox Glacier, and the Copland and Twain Rivers, and many prominent mountain peaks. Some of the smaller reserves have been set aside for historical and anthropological reasons, but most are scheduled in order to preserve scenery and natural vegetation.

#### Announcements

THE Kelvin Medal of the Institute of Civil Engineers for 1932 has been awarded to the Marchese Guglielmo Marconi, and the presentation will be made by Lord Rutherford at the Institute on Tuesday next, May 3, at 5 P.M.

A VARLEY centenary commemoration meeting will be held at the Institution of Electrical Engineers on

May 5 A short discourse on the lives and work of Cromwell Fleetwood Varley (April 6, 1828) and Samuel Alfred Varley (March 22, 1832) will be delivered by Lieut-Col A G Lee The annual general meeting of the Institution will follow this meeting

THREE public lectures arranged by the National Institute of Industrial Psychology (under the Heath Clark Bequest), on "Psychological and Social Factors in Business Rationalisation", will be delivered by Dr Charles S. Myers, principal of the National Institute of Industrial Psychology, May 4, 11, and 18, at 5 30 P M The lectures will be given at the London School of Economics and Political Science, Houghton Street, Aldwych, W C 2

THE writer of the obituary notice of the late Sir Horace Plunkett which appeared in NATURE for April 16 has been reminded that Sir Robert Blair was Assistant Secretary for Technical Instruction in the new Irish Department from 1900 until 1904, before he became Education Officer of the London County Council The two 'aliens' whom Sir Horace introduced were thus both Scots

A PRELIMINARY programme has been issued of the centenary meeting of the British Medical Association, to be held in London on July 21-30 under the presidency of Lord Dawson of Penn The meetings will be held at the British Medical Association House, Tavistock Square, W C 1 Lord Dawson will deliver his presidential address on July 26 at the Queen's Hall The popular lecture to the Association will be delivered on July 29 by Prof Julian S Huxley An exhibition of surgical appliances, drugs, foods, books, etc., will be open on July 26-29 at the University of London, Imperial Institute Road, S W.7 On July 24 a pilgrimage will be made to Worcester to unveil two memorials to Sir Charles Hastings, who founded the Association there in 1832

THE programme of experiments to be carried out during the coming season at Jealott's Hill, the Agricultural Research Station of Imperial Chemical Industries, Ltd., at Bracknell, near Maidenhead, Berks, includes experiments on fertilisers for grain, root, and green crops, and also on the intensive management of grassland The demonstrational small-holding has entered its second complete season, and the results of the first year's working are available An open invitation is extended to all interested in agriculture to inspect the Station Visitors are the guests of the Station at lunch or tea, but it is desirable that two or three days' notice should be given of an intended visit

THE advanced courses in anthropology, sociology, and comparative philology in the University of London announced for delivery in May promise to be of exceptional interest On May 2, 4, and 6, Prof G Morgenstierne of the University of Gothenburg will lecture on "The Káfirs of the Hindu Kush" The lectures will be delivered at 5 30 P M at the School of Oriental Studies, Finsbury Circus, E C, and will deal with the ethnology and culture of the

people, as well as with their linguistics On May 5 and 12, at 5 P M, Dr R R Marett, Rector of Exeter College, Oxford, will lecture at the London School of Economics on "Covenant in Primitive Economics, Law, and Religion" Prof A M Tallgren, professor of archaeology of Finland and the Northern Countries in the University of Helsingfors, will lecture at University College on May 23 and 25 on "Central Asiatic and Siberian Rock Pictures" The lectures will begin at 5 30 Admission to all these lectures is free and without ticket

A CATALOGUE of second-hand books on natural history has been issued by James Thim, 54-56 South Bridge, Edinburgh The 2497 items in the list range over a wide field in zoology, botany, and agriculture and husbandry

A NEW book by Max Planck, entitled "Where is Science Going?", with introduction and epilogue by Einstein, is promised by Messrs Allen and Unwin for the autumn These publishers also announce "Science A Symposium", a collection of essays by Bertrand Russell, Prof Julian Huxley, Prof J B S Haldane, Hilaire Belloc, Sir Oliver Lodge, Sir Thomas Holland, John Baker, Hugh L'Anson Fausset, and Prof H Levy

A NEW publication dealing with general and comparative physiology has been undertaken by the Wistar Institute of Anatomy and Biology, Philadelphia This *Journal of Cellular and Comparative Physiology*, which will be published in alternate months, under a responsible board of editors, commenced publication on Feb. 20 The volume will contain about 500 pages and may be closed with any issue The price will be 5 50 dollars outside the United States

APPLICATIONS are invited for the following appointments, on or before the dates mentioned—An assistant lecturer in agricultural economics in the University of Leeds—The Registrar, University, Leeds (May 2) An assistant veterinary inspector under the Surrey County Council—The Chief Veterinary Officer, County Hall, Kingston-upon-Thames (May 10) A superintendent of Epping Forest—The Town Clerk, Guildhall, E C 2 (May 11) A woman lecturer in geography at St Gabriel's College, Camberwell—The Principal, St Gabriel's College, Cormont Road, Camberwell, S E (May 14) A lecturer in geography at Armstrong College—The Registrar, Armstrong College, Newcastle-upon-Tyne (May 14) Two assistant lecturers in the School of Economics and Commerce, Dundee, in, respectively, industrial administration and commerce—The Principal, School of Economics and Commerce, Dundee (May 23) A director of the British Non-Ferrous Metals Research Association—The Chairman of the Association, 168 Regent Street, W 1

ERRATUM—In the article "Flame Movements in Gaseous Explosions", in NATURE for April 16, p 565, line 5, for "Campbell and Woodward (1926)" read "Campbell and Woodhead (1926)"

## Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

## Disintegration of Lithium by Swift Protons

In a previous letter to this journal<sup>1</sup> we have described a method of producing a steady stream of swift protons of energies up to 600 kilovolts by the application of high potentials, and have described experiments to measure the range of travel of these protons outside the tube. We have employed the same method to examine the effect of the bombardment of a layer of lithium by a stream of these ions, the lithium being placed inside the tube at 45° to the beam. A mica window of stopping power of 2 cm. of air was sealed on to the side of the tube, and the existence of radiation from the lithium was investigated by the scintillation method outside the tube. The thickness of the mica window was much more than sufficient to prevent any scattered protons from escaping into the air even at the highest voltages used.

On applying an accelerating potential of the order of 125 kilovolts, a number of bright scintillations were at once observed, the numbers increasing rapidly with voltage up to the highest voltages used, namely, 400 kilovolts. At this point many hundreds of scintillations per minute were observed using a proton current of a few microamperes. No scintillations were observed when the proton stream was cut off or when the lithium was shielded from it by a metal screen. The range of the particles was measured by introducing mica screens in the path of the rays, and found to be about eight centimetres in air and not to vary appreciably with voltage.

To throw light on the nature of these particles, experiments were made with a Shimizu expansion chamber, when a number of tracks resembling those of  $\alpha$ -particles were observed and of range agreeing closely with that determined by the scintillations. It is estimated that at 250 kilovolts, one particle is produced for approximately  $10^9$  protons.

The brightness of the scintillations and the density of the tracks observed in the expansion chamber suggest that the particles are normal  $\alpha$ -particles. If this point of view turns out to be correct, it seems not unlikely that the lithium isotope of mass 7 occasionally captures a proton and the resulting nucleus of mass 8 breaks into two  $\alpha$ -particles, each of mass four and each with an energy of about eight million electron volts. The evolution of energy on this view is about sixteen million electron volts per disintegration, agreeing approximately with that to be expected from the decrease of atomic mass involved in such a disintegration.

Experiments are in progress to determine the effect on other elements when bombarded by a stream of swift protons and other particles.

## Isotopic Constitution of Lead from Different Sources

THANKS to the generous co-operation of Dr. v. Grosse and other chemists in supplying me with the requisite rare materials, I have been able to repeat and amplify my analyses of lead from different geological sources. During these experiments, which I hope to extend, technical improvements were effected so that, in spite of the difficulties inherent in the problem, results have been obtained upon which considerable reliance may be placed.

The effect of the presence of hydrides due to the methyl compounds has been measured and can be allowed for. Under the particular conditions used, it amounts to 2.3 per cent. Thus in the lightest lead (II) though the line 207 had an apparent intensity of 9.5 (line 206 = 100), its true relative abundance is estimated to be  $7.2 \pm 0.3$ , in good agreement with the value 7 assumed by Lord Rutherford<sup>1</sup> for his calculations on actino-uranium. Several rare isotopes previously suspected in ordinary lead<sup>2</sup> have now been confirmed but their abundances are too small to be certain. The percentage analyses are as follows—

| Chemical      | I      | II      | III     | IV      |
|---------------|--------|---------|---------|---------|
| Atomic Weight | 207.22 | 206.048 | 206.195 | 207.90  |
| 203           | (0.04) |         |         |         |
| 204           | (1.50) |         |         |         |
| 205           | (0.03) |         |         |         |
| 206           | 27.75  | 93.3    | 85.9    | 4.6     |
| 207           | 20.20  | 6.7     | 8.3     | 1.3     |
| 208           | 49.55  | (0.02)  | 5.8     | 94.1    |
| 209           | (0.85) |         |         |         |
| 210           | (0.08) |         |         |         |
| Mean Mass     |        |         |         |         |
| Number        | 207.19 | 206.067 | 206.20  | 207.895 |

I Ordinary lead

II Lead from Katanga pitchblende (Honigschmid and Birkenbach *Ber. Deutsch. Chem. Gesell.*, 56, 1837, 1923)

III Lead from Wilberforce uraninite (Baxter and Bliss, *J. Amer. Chem. Soc.*, 52, 4851, 1930)

IV Lead from Norwegian thorite (Fajans, *Sitz. Heidelberger Akad. Wiss.*, 3, 1918)

The packing fractions of the leads will be very difficult to ascertain, but appear to be in the region 0 to +1. They will tend to cancel the correction (still uncertain) to the chemical scale, so that the mean mass-numbers should show agreement with the chemical atomic weights, which is the case. It is noteworthy that the quantities of 206 and 207 in (IV) do not correspond to those expected from ordinary lead present as an impurity.

## Oxygen and Everest

ON the interesting subject of the need for oxygen on Mount Everest, Prof. J. Barcroft has made the remark, before Section I of the British Association, that the whole matter is now merely "an engineer's problem"—the problem of designing a light and efficient oxygen breathing apparatus. This point of view is ably supported by Prof. Margaria<sup>1</sup>. There is, however, something more—namely, the disadvantage of acclimatisation in a man using such apparatus. If it is one of the 'open circuit' type, acclimatised breathing causes a huge waste of oxygen and adds correspondingly to the difficulty of transportation. Yet a man dare not relinquish this physiological condition, even if he could. For if he relinquished it, he would die of asphyxia as soon as he took the apparatus off.

A man adjusted to sea-level conditions breathes about ten litres of air for each gram of carbon dioxide exhaled. When acclimatised to 20,000 ft he breathes about twenty litres per gram of carbon dioxide. At rest at sea-level he breathes 5-7 litres of air per minute. At rest on the North Col of Mount Everest, with the same carbon dioxide production, he probably breathes 10-14 litres. This does not incommode him at all. When he exercises and produces 4-6 gm of carbon dioxide per minute, he breathes 40-60 litres at sea-level, but 80-120 litres on Mount Everest. 40-60 litres per minute is merely heavy breathing, but 80-120 litres is intolerable for more than a minute or two. A man cannot walk while doing it. The reason for this difference lies in the fact that, in acclimatisation, the blood alkali is reduced in proportion to the altitude and oxygen pressure to which the man has become adjusted, and the less the blood alkali, the larger must be the 'dilution ratio' that is, the volume of air breathed per gram of carbon dioxide produced and exhaled. This adjustment is acquired very slowly, and is reversed again equally slowly, through days or even weeks, on return to sea-level.

As Prof. Barcroft was the first to show, the balance of acid and alkaline elements in the blood is the same at altitudes as at sea-level, but the amounts of each are not the same. The acid element is carbonic acid in equilibrium with the carbon dioxide in the air of the lungs and controlled by their ventilations. It was shown by Haldane, Douglas, Schneider, and Henderson on Pike's Peak that, because of the increased breathing, the partial pressure of carbon dioxide in the lungs and, therefore, the carbonic acid of the blood are diminished in proportion to the altitude. So also are the bicarbonates, which are the alkaline element in the blood. The reduction of the acid proportionally with the alkali is essential to maintain the hydrogen ion concentration of the blood at its normal value. In order to keep the quantity of carbonic acid down to an amount to correspond with the decreased blood alkali, the volume of breathing must be increased in inverse proportion to the bicarbonates in the blood.

Accordingly, when a man fairly well acclimatised to the altitude of the North Col puts on an oxygen apparatus and does the heavy work of climbing with it on his back, the increased production of carbon dioxide induces so large a volume of breathing that he can make but a few steps at a time. The hyperpnœa may be almost as intolerable as if he were breathing merely the thin air, for in the man it is induced by the large 'dilution ratio' due to the low blood alkali. Without the apparatus, the oxygen deficiency merely reinforces, to some extent, the hyperpnœa due to carbon dioxide. Inhalation of oxygen, therefore, does little to ease the violence of the breathing after each few yards of the struggle upward.

Some men acclimatise slowly and with difficulty. They suffer from prolonged mountain sickness, as Dr Douglas and Prof Schneider did on Pike's Peak,<sup>2</sup> and as, I believe, Prof Barcroft does to an even greater extent. For them oxygen is the very breath of life. Others like Dr J. S. Haldane (as I saw on Pike's Peak), and like Mr Odell and others of the advanced parties in the attacks on Mount Everest, acclimatise so easily and well that oxygen helps them less than the weight of an apparatus impedes. For the first type, who have what we may call 'sea-level respiratory centres', the ascent of Everest is largely an "engineer's problem." They should fly direct and wholly unacclimatised to the North Col, don an improved apparatus, make the ascent, and get back below 15,000 ft while the supply of oxygen holds out. The other type acclimatizes readily, and during the gradual

ascent through Tibet they become so well adjusted to low pressures of oxygen that, although the risks are great, a party of such men with no apparatus may some day reach the summit.

There is one development, however, that, I think, we shall never see—namely, agreement between the advocates of oxygen apparatus and those whose experience teaches them to rely wholly on acclimatisation.<sup>3</sup> Prof Margaria comments upon the fact that on this matter "there is no accord among physiologists", to which I would add that the disagreement lies not in their minds merely, but fundamentally in their respiratory centres. How can a man of either opinion accept the other, when his own is to him as obvious as breathing? The whole science of respiratory physiology would to-day be different from what it is if its author, Dr Haldane, had not happened to have a respiratory centre of the type that is most completely controlled by carbon dioxide, yet acclimatizes fairly easily. Those who disagree with him on such matters as acclimatisation, do so, not so much because they think differently, as because they breathe differently.

### The Cry of Tin

It is an observation of respectable antiquity that when a bar of tin is bent it emits a characteristic creaking, known as the 'cry of tin.' According to Mellor,<sup>1</sup> who is one of the few authorities to refer to the subject, the cry "is supposed to be produced by the grinding of the crystals against one another during the bending of the metal", and I have been unable to find in the literature any more definite explanation of its origin. In the course of some experiments which I have been carrying out with Prof E. N. da C. Andrade on single crystal wires I have made observations which, I think, make possible a rather more precise attribution of the sound.

I have obtained the cry with cadmium as well as with tin. When single crystal wires of these metals are stretched, the deformation takes place in two stages, a slip on the glide planes, which constitute in both cases a unique system, being succeeded by a mechanical twinning on a specified plane. The twinning does not take place until after a definite amount of glide extension has occurred, which enables the two phenomena to be studied separately.

With single crystal wires no sound is produced during the glide stage of extension, but with both metals twinning is accompanied by the characteristic creaking or tearing sound. The same sound also occurs when such wires are violently bent or twisted, a process which gives rise to the surface marking characteristic of twinning, although it does not allow the separation of twinning from other effects in the way that simple extension does.

The tin with which the phenomenon is normally observed is in a polycrystalline state. Although the cry occurs when polycrystalline cast rods of both tin and cadmium are bent, drawn wires of small diameter do not give it unless they are annealed, or, in other words, the production of the sound depends on the size of the crystallites being greater than a certain minimum—larger crystals, of course, being subjected to more severe strain when the metal is bent. It is reasonable to suppose that the cry is an accompani-

ment of twinning in the case of the polycrystalline state as well as in the single crystal state

Preliminary measurements on cadmium indicate that whereas the heat evolved in the twinning is of the order of 0.1 calories per gram, less than one-tenth of this amount is produced during the whole extension accompanying gliding, although this extension is considerably greater than that due to the twinning. The measurements, which are being followed up with more accurate methods, give, at present, only rough approximations, but suffice to establish clearly this very much greater heating which accompanies twinning. This observation suggests that some of the mechanical energy that is supplied to the lattice to cause twinning is afterwards liberated as heat energy and, in particular cases, as sound energy, the cry of tin and cadmium being a manifestation of the latter.

It may be added that while a cry can be produced from zinc, which crystallises in the hexagonal system and twins readily, I have not been able to produce a cry with any metal crystallising in a cubic system, for which twinning does not take place.

BRUCE CHALMERS

Physics Laboratory,

<sup>1</sup> "Complete Treatise of Inorganic Chemistry", vol. 7, p. 296

THE observations of Dr Chalmers described in the above letter, which are being followed up, seem to me likely to prove of considerable importance for elucidating the problem of twinning. The generation of heat agrees with the view that, in twinning, the molecules, when sufficient energy is applied, slip from one equilibrium position to another, about which they then execute heavily damped vibrations, the energy of vibration dissipating itself in heat and probably in radiation of a frequency of the *Reststrahlen* order. The sound indicates that the twinning does not take place over the whole region of twinning simultaneously, for the sound frequency is much too low to be connected with the vibration of molecules or molecular units, but is propagated from layer to layer with a velocity or velocities of the order of sound velocity. It is possible that in the case of substances where sudden twinning is unaccompanied by audible sound, the sound exists, but is of too high a frequency to be heard.

#### Climatic Changes in British Somaliland

THE alternation of climatic conditions in East Africa during Pleistocene time has recently been brought into prominence in connexion with the history of early man, and it accordingly became of interest, the opportunity presenting itself, to ascertain whether the results obtained in Kenya could to any degree be paralleled in Somaliland.

Fifteen months of almost continuous travel in the British Protectorate led to tentative first conclusions, which, if the coastal belt could have been included, would probably have been more definite. Evidence in the districts traversed was somewhat hard to find, but in the west, the Buramo district, tenanted by the Gadabursi people, steep V-shaped valleys give proof of an early and strong period of erosion, whereby bold, rugged scenery has been carved out of a complex of crystalline rocks. To this time may also be attributed sundry high-level deposits, that is, in the east on the Sorli Haud, and in the Gadabursi country, where conglomerates, often extremely coarse, were noted in several places, at various levels above the present surface of weak and spasmodic erosion.

It is interesting that, although the final movement of the coast-line was one of elevation, this was preceded, in the west at least, by subsidence, whereby deposits of coral and shelly sands and clays were laid down. At Zeilah, these proved to be about three hundred feet thick and were underlain by a spherulitic rhyolite. Some twenty-five miles to the south and about fifteen miles from the sea, these marine deposits are replaced by uniform sticky brown clays, containing occasional pebbles, doubtless deltaic and lagoon deposits. A bore put down in such a position did not reach the floor of crystalline or pre-Pleistocene rocks at 250 ft, but was probably not far off. It is to the later part of this period of steady deposition on the west that I would attribute the widely distributed infilling of the hollows and valleys formed by the earlier erosion with a remarkably uniform, slightly clayey sand, the 'tug alluvium',\* of a reddish-brown colour, and sufficiently consolidated to stand in a vertical face. Occasionally small gasteropods, *Planorbis*, for example, are abundant.

This alluvium, although typically unbedded, shows evidence now and again of rapid deposition, for thin layers or strings of pebbles and local false-bedding can be seen in almost every section. In these sands occur, sparingly, artefacts which should afford an archaeological date.<sup>1</sup> Of the period between the erosion of the valleys and the infilling with tug alluvium there appears little evidence, but near Buramo the bottom of the tug section is a very altered basic rock, clearly the result of weathering of the hornblende-schists of the neighbourhood, but to a certain extent reconstructed, as pebbles are found in it.

The alluvium itself, probably seldom exceeding a hundred feet in thickness, has been cut to form the characteristic drainage channels or 'tugs' of Somaliland. Now, these only occasionally contain flowing water, and although spates may assume torrential proportions and carry much sediment, it is clear that the tugs were formed by true rivers, which preceding the present period of slow desiccation, indicate a wet phase. During this time, the final uplift of the coast may have taken place, amounting, according to Dr Macfadyen, to 750 ft in the Berbera district, although apparently much less in the west, where, however, more work is needed. A considerable thickness of alluvium forms the great plains characteristic of the south-central part of the Protectorate.

A well, put down fifty miles east-south-east by south of Hargeisa, passed through 112 ft of calcareous terra-cotta alluvial clay, before reaching the white and brown marls and limestones from which it was doubtless derived. It contained, in this bore, no pebbles, and its deposition is concluded to be of a lacustrine nature and to belong to the period of the tug alluvium. Leakey's "Second major pluvial" I would correlate tentatively with the deposition of the latter, with the period of the erosion of those valleys in which the alluvium lies and the formation of the old conglomerates, his 'Kamasian' and probably somewhat antecedent time, the dissection of the tug alluvium with a post-pluvial wet phase.

The correlation is admittedly unsatisfactory, and it is probable that the variations of climates in British Somaliland will, when worked out, show differences from those of Kenya.

### The Nuclear Spin of Arsenic

THE fine structures occurring in the lines of the spectrum of As II have been observed by me in the region  $\lambda\lambda 6400-4300$  by means of a Fabry-Perot interferometer with plate separations varying from 5 mm to 25 mm. The source employed was a Geissler tube containing arsenic, helium at a pressure of 2 mm being circulated through the tube. Fifty lines have been observed, thirty-three of which are single, the rest showing fine structure. Most of the lines showing structure involve transitions between the  $4p\ 5s$  and  $4p\ 5p$  electron configurations and divide themselves into two distinct groups. These are, first, degraded regular series, which arise from the fact that only one of the terms involved, usually the  $4p\ 5s$  term, shows appreciable structure, and secondly, complex patterns due to appreciable structure in both upper

FIG 1

and lower terms. The gross multiplet structure has been analysed by Dr K. R. Rao, who has kindly allowed me to use his unpublished data, and the fine structure observations confirm the gross structure analysis in detail.

Of the  $4p\ 5s\ ^3P$  terms, the terms with  $j=0$  are single, those with  $j=1$  are triple, and those with  $j=2$  are quadruple. The nuclear spin is therefore  $\frac{1}{2}$ . This value is amply confirmed by other data, and the fine structure analyses of the various lines check one another extremely well. For example, the line  $4p\ 5s\ ^3P_0-4p\ 5p\ ^3D_1$  is a regular triplet degraded to the red, the intervals being 120 and  $78\text{ cm}^{-1} \times 10^{-3}$ . This is therefore the term structure for  $4p\ 5p\ ^3D_1$ , since  $4p\ 5s\ ^3P_0$  remains single. Also, the line  $4p\ 5s\ ^3P_1-4p\ 5p\ ^3P_1$  is an extremely sharp triplet degraded to the violet, with intervals 194, 117. Other data prove that the structure of the  $4p\ 5p\ ^3P_1$  term is quite negligible, so that this gives the structure of the  $4p\ 5s\ ^3P_1$  term. From these the fine structure of the line  $4p\ 5s\ ^3P_1-4p\ 5p\ ^3D_1$  can be predicted, and, as shown in Fig 1, the agreement with the structure

actually observed is remarkably exact, both as to intensities and intervals. Since the components  $bc$  and  $fg$  respectively fall right on top of one another, their intensities have been added in forming the predicted pattern.

Attention may be directed to the relatively coarse structure of the  $4p\ 5p\ ^3D_1$  term as compared with the  $4p\ 5s$  terms. Since this term possesses no penetrating  $s$  electron, it is to be expected at first that the structure will be small. However, Breit<sup>1</sup> has shown that in the heavier atoms a  $p_{\frac{1}{2}}$  electron behaves with respect to the nucleus as if it were penetrating, and since the  $4p\ 5p\ ^3D_1$  term is built up out of two  $p_{\frac{1}{2}}$  electrons with parallel coupling, this may be the correct explanation of the relatively coarse structure, as the atomic weight of arsenic is 79. A detailed account of the fine structures will be published elsewhere shortly.

### Infra-Red Absorption Spectra of the Oxides of Chlorine

WE have recently completed an examination of the infra-red absorption spectra of the monoxide and dioxide of chlorine. The unstable nature of these substances demanded the use of a monochromator method; this has the additional advantage of an increased purity of spectrum, but even under these conditions there is a considerable amount of scattered radiation in the region of longer wave-lengths. We have endeavoured to take advantage of the alteration in the chromatic foci of rocksalt to stop out most of the scattered light, but owing to the lack of transparency of this substance beyond  $18\mu$  (the optical train included rocksalt lenses and plates for the absorption cells and thermopile case), we obtained no measurable deflections on the galvanometer. The provision of optical parts of potassium bromide should eventually solve this difficulty. The observed bands for  $\text{ClO}_2$  are recorded in the accompanying Table.

| Band | ( $\lambda$ ) $\mu$ | Maxima ( $\text{cm}^{-1}$ ) | P-R $\Delta\nu$ ( $\text{cm}^{-1}$ ) | Relative Intensity | Origin          |
|------|---------------------|-----------------------------|--------------------------------------|--------------------|-----------------|
| B    | 10.57               | 932<br>963                  | 31                                   | 30                 | $\nu_2$         |
| C    | 9.017               | 1095<br>1105<br>1123        | 28                                   | 80                 | $\nu_3$         |
| D    | 5.307               | 1870<br>1884<br>1900        | 30                                   | 0.5                | $2\nu_2$        |
| E    | 4.916               | 2034                        | —                                    | 4                  | $\nu_2 + \nu_3$ |
| F    | 4.246               | 2355                        | —                                    | 0.5                | $2\nu_3$        |

$\nu_1$  for this molecule falls outside the range of our spectrometer; recent work by Urey and Johnston<sup>1</sup> gives a probable value of  $529\text{ cm}^{-1}$  for this fundamental. The spectrum is very similar indeed to that of sulphur dioxide, this fact is perhaps to be connected with the 'odd' electron structure of  $\text{ClO}_2$ , there being no corresponding proper function in this case to satisfy the odd electron, and except for the instability associated with this, we have for the rest of the molecule much the same external electronic structure in the two substances.

We have extended the examination of the possible modes of vibration for the symmetrical triangular

molecule, and a determination of the molecular constants with given conditions makes it finally probable that both  $\text{SO}_2$  and  $\text{ClO}_2$  are equilateral triangles, the length of side being approximately 1.37 Å in each case, while there is a single linking between the oxygens and the central atom. The two molecules both have in addition a non-localised proper function, which in the case of sulphur dioxide is filled with two electrons giving a non-localised bond accounting for the stability of the substance compared with the chlorine compound. This application of a conception recently due to Hund<sup>2</sup> is confirmed by the values of the force constants, which are  $9.7 \times 10^5$  dynes per cm for  $\text{SO}_2$ , and  $6.7 \times 10^5$  dynes per cm for  $\text{ClO}_2$ . An equilateral triangular structure is probably the only structure compatible with non-localised proper functions.

In the case of chlorine monoxide certain of the bands overlap, and the observed values cannot at present be taken as more than reasonable approximations. We have  $\nu_1 = 639$ ,  $\nu_2 = 973$ ,  $\nu_3 = 1245$ ,  $2\nu_1 = 1305 \text{ cm}^{-1}$ . On the older polarisation theory one would have expected a rectilinear structure for this substance. Examination shows, however, that the molecule is triangular with vertical angle approximately  $90^\circ$  and again single linkings ( $f_1 = 6 \times 10^5$  dynes/cm.) between the chlorine and oxygen atoms. The existence of a considerable repulsive force between the two chlorine atoms is shown by the magnitude of  $f_2$ , the force constant for the particles at the base of the triangle, which rises from  $1.7 \times 10^5$  dynes/cm for  $\text{SO}_2$  and  $\text{ClO}_2$  to  $5 \times 10^5$  dynes per cm for  $\text{Cl}_2\text{O}$ .

### Fluted Band at $\lambda 3900 \text{ Å}$ . in the Spectrum of Mercury

It has already been observed by J. Stark and by others that a fluted band system of mercury at  $\lambda 3900 \text{ Å}$  is superposed on the continuous spectra, covering the visible and the ultra-violet regions, but, so far as we know, nothing has been reported about the origin of this band.

We have observed the band, and Fig. 1 is a reproduction of its photometric curve. We excited the

FIG. 1—Photometer curves of the mercury band spectrum with wave-length scale in angstrom units

vapour with a high-frequency oscillatory current of about  $5 \times 10^8$  cycles. The oscillation was produced by a spark maintained by a valve oscillator working at  $3 \times 10^5$  cycles. On plotting the frequency differences as a function of wave-number, as shown in Fig. 2, the convergence limit was estimated to be  $27,150 \text{ cm}^{-1}$ ,

which falls near the strong triplet lines at  $\lambda 3650 \text{ Å}$ . Therefore it seems reasonable to assume that the band has a close relation with these lines. From this point of view, it is considered that the bands are connected with the  $3^3D$  state of the mercury atom,

FIG. 2

consequently they are emitted by the transitions between the levels the dissociation products of which are the excited  $3^3D$  atom, and the normal, and the next lower levels connected with the  $2^3P$  of the atomic states, from which, as it is usually accepted, the other visible and ultra-violet band systems are initiated.

### A New Band System of Beryllium Oxide

In an attempt to get bands of the beryllium molecule, I found in an arc between a carbon and a beryllium electrode several new bands in the red and infra-red region. The analysis of these bands showed that they are, however, not due to beryllium but to the oxide,  $\text{BeO}$ , the lower level being the same as that of the well-known visible  $\text{BeO}$ -bands analysed by Bengtsson,<sup>1</sup> and Rosenthal and Jenkins.<sup>2</sup> As until now only two electronic states (both  $^1\Sigma$ ) of the molecule  $\text{BeO}$  are known, namely, the lower and upper states of the visible bands, it seemed worth while to analyse the new bands in detail, in order to get more information about the electronic structure of this molecule, especially with respect to the question of valence and dissociation products.

The heads of the bands, which are shaded towards the red, are not very pronounced, and since there is much overlapping of different bands, the whole system looks under high dispersion rather like a many-line spectrum. The analysis showed that in spite of their complicated appearance, the bands have only single  $P$ ,  $Q$ , and  $R$  branches. As the lower state is  $^1\Sigma$ , the transition is  $^1\Pi \rightarrow ^1\Sigma$ , the  $^1\Pi$  level lying between the two  $^1\Sigma$  levels mentioned above. This upper level is just the state one would expect according to the electronic configuration of  $\text{BeO}$ .<sup>3</sup>

So far, three bands have been analysed (Table 1)

TABLE 1

| $v'$ | $v''$ | 0     | 1     |
|------|-------|-------|-------|
| 0    |       | 13647 |       |
| 1    |       | 14710 |       |
| 2    |       |       | 14293 |

The  $v'$ -numbering may be shifted, if more bands are found, farther in the red. The vibrational quantum of the upper state ( $^1\Pi$ ) is very much lower than that of the ground state ( $^1\Sigma$ ), as calculated by Rosenthal and Jenkins.<sup>2</sup> The  $\Delta G'$  values are  $\Delta G'_1 = 1063$ ,

$\Delta G''_1 = 1047$ ,  $\Delta G''_2 = 1464$ ,  $\Delta G''_3 = 1440$  (calculated from band origins, not from heads) The same is true for the values of  $B$  (Table 2) In Table 2 are given the  $B$  values for both states, as well as those for  $r$  and  $a$  The  $B''$  values coincide with those calculated by Rosenthal and Jenkins for the lower  $^{12}\Sigma$  level

TABLE 2

|                       | $B$   |                            |
|-----------------------|-------|----------------------------|
| $^{12}\Sigma$ $v''=0$ | 1 643 | $r''_0 = 1.33 \text{ \AA}$ |
| $v''=1$               | 1 623 | $a''_0 = 0.020$            |
| $^{12}\Pi$ $v'=0$     | 1 296 |                            |
| $v'=1$                | 1 230 | $r'_0 = 1.50 \text{ \AA}$  |
| $v'=2$                | 1 266 | $a'_0 = 0.015$             |

### Coacervation

In a preliminary communication Kruyt and Bungenberg de Jong<sup>1</sup> proposed the name *coacervation* for the phenomenon of separation into two liquid layers in systems containing one or more compounds in the colloidal state

The separation takes place under the influence of several agents (for example, electrolytes, alcohols, polyphenols) at a temperature above the temperature of gelation

Kruyt and de Jong suggested a typical difference between the analogous phenomena in molecularly dispersed systems, studied by the classical phase-theory, and the peculiar type of flocculation already mentioned

We have analytically determined the composition of the co-existing liquids in the systems water-gelatin-ethanol, w.-g.-sodium sulphate, and w.-g.-resorcinol. The preparation used in our experiments was ash-free iso-electric gelatin, prepared by means of Loeb's method

It should be pointed out that, in all cases, we were dealing with perfect equilibria and that nearly all the protein was present in the lower layer, the upper layer being practically free of gelatin

Moreover, there is a decided difference between the influence of ethanol and sodium sulphate on one hand and resorcinol on the other as indicated below.

| Ethanol                                                             | Sodium sulphate | Resorcinol                                                         |
|---------------------------------------------------------------------|-----------------|--------------------------------------------------------------------|
| Rather large concentrations required for separation                 |                 | Separation takes place at exceedingly small concentrations         |
| Ratio of water to agent greater in lower layer than in upper layer  |                 | Ratio of water to agent smaller in lower layer than in upper layer |
| Separation does not disappear at higher concentrations of the agent |                 | Separation disappears at a certain concentration of the agent      |

The lower layer may be considered as an accumulation of micellæ, only separated by a binary liquid. This explains the name 'coacervate' for the sub-layer (*acervus* = heap)

It is well known that Einstein's formula for the relative viscosity of sols enables us to calculate the volume connected with the colloidal matter in solution. We have plotted this volume against the concentration of one of the above-mentioned agents. We have also, in the same diagram, shown the

volumes of the corresponding coacervates, calculated per gram gelatin. As a matter of fact, the data used by the first method were obtained at lower concentrations, whereas the results of the second experiments were related to large concentrations of the agent. It is interesting to note that both curves nearly coincide.

Through these and other facts we are led to the conclusion that one might well consider the micellæ as a 'wall-substance' covered with a layer of solvating matter. It will be noted here that our analysis brings out the relationship existing between the composition of the solvate film and the upper layer.

The fact is that the presence of a solvate film has always been considered as one of the stabilising factors of a sol (electric charge and solvation), but in our case it is clear that we have to seek the stabilising factor especially in the transition solvate film-medium.

The existence of stability is due to the fact that this transition bears a continuous character. Under the influence of dehydrating agents, this transition becomes discontinuous at the critical concentration of the agent: the diffuse solvation film has become concrete and thus gives rise to a surface tension. The origin of coacervation is decrease of the total free surface energy.

### Fats of Brown Sea-weeds

INVESTIGATIONS recently carried out in this department on the marine algæ have shown that there would appear to be some connexion between the depth of immersion of such weeds and their metabolism, as expressed by their chemical composition. Such connexion has been traced in regard to their carbohydrate<sup>1</sup> and nitrogenous<sup>2</sup> constituents, and the present investigation was undertaken with the view of ascertaining whether a similar connexion holds for the fatty constituents.

The weeds examined in the present instance are *Pelvetia canaliculata*, *Pelvetia canaliculata forma libera*, *Fucus vesiculosus*, and *Laminaria digitata*. *Pelvetia libera* is a free floating marsh form which is exposed to desiccation for considerable periods of time, being immersed only during spring tides. *Pelvetia canaliculata* grows at a lower zone, fixed to stones or rocks, and is covered with water for fairly long periods daily. *Fucus vesiculosus* grows somewhat lower than *P. canaliculata*, but is considerably more exposed than *Laminaria digitata*, which, being a deep sea-weed, is only exposed for a short period during spring tides. These sea-weeds therefore present a fairly wide range of variation in regard to habitat conditions. How far these conditions are reflected in their chemical composition may be seen from the results below.

The petrol ether extract—though representing a mixture of substances besides true fat—shows a regular decrease with depth of immersion, and the same holds for the true fat content, as calculated from the fatty acids isolated from the extracts.

|                              | Petrol Ether Extract | Iodine Value of Extract | Percentage True Fat |
|------------------------------|----------------------|-------------------------|---------------------|
| <i>Pelvetia libera</i>       | 8.0                  | 106                     | 6.2                 |
| <i>Pelvetia canaliculata</i> | 4.9                  | 115                     | 3.6                 |
| <i>Fucus vesiculosus</i>     | 2.6                  | 114                     | 1.9                 |
| <i>Laminaria digitata</i>    | 0.3                  | 123                     | 0.16                |

The figures in all cases are calculated on oven-dry material.

Analysis of the extracts was confined to a separation of the unsaponifiable residue and fatty acids and the determination of their iodine values. The unsaponifiable residue, calculated as a percentage of the petrol ether extract, was found to increase with depth of immersion as follows

|                        | Unsaponifiable Residue |                    | Iodine Value of Unsaponifiable Residue |
|------------------------|------------------------|--------------------|----------------------------------------|
|                        | Percentage of Extract  | Percentage of Weed |                                        |
| <i>P. libera</i>       | 7.6                    | 0.61               | 124                                    |
| <i>P. canaliculata</i> | 10.8                   | 0.53               | 117                                    |
| <i>F. vesiculosus</i>  | 16.9                   | 0.44               | 136                                    |
| <i>L. digitata</i>     | 25.9                   | 0.078              | 125                                    |

It will be seen, however, that the iodine value, as determined by the pyridine bromine method, shows no regularity. The percentages of fatty acids, calculated on the petrol ether extract, together with the iodine values of the acids, are given in the following table

|                        | Percentage of Fatty Acid | Iodine Value |
|------------------------|--------------------------|--------------|
| <i>P. libera</i>       | 72.5                     | 107          |
| <i>P. canaliculata</i> | 69.9                     | 124          |
| <i>F. vesiculosus</i>  | 71.6                     | 108          |
| <i>L. digitata</i>     | 49.9                     | 110          |

It should be noted that the fatty acids when isolated tend to reduce their iodine value on exposure to air, and although evaporations were carried out *in vacuo*, a certain amount of exposure was inevitable, and consequently the values given above may be somewhat low. A further separation of the fatty acids into solid and liquid acids was carried out in the case of two sea-weeds representing the extremes of habitat, and the results, calculated as percentages of the total fatty acids, are as follows

|                    | Solid Acids | Liquid Acids |
|--------------------|-------------|--------------|
| <i>P. libera</i>   | 11.5        | 78.7         |
| <i>L. digitata</i> | 17.7        | 72.2         |

It appears from the foregoing that, while the general character of the fats is about the same, there is a distinct difference in the proportion of unsaponifiable residue and in the absolute amounts of fat in these sea-weeds

#### Light as a Factor in Sexual Periodicity

I OBSERVE with interest the letters of Dr M. A. H. Tincker and Mr J. T. Cunningham<sup>1</sup>. In regard to the former, I should like to point out that some observations on the periodicity of plankton diatoms have been made. Only in lakes with a relatively high percentage of dissolved salts do diatoms attain great maxima, and vast maxima have only been found to occur in a few British lakes. Many plankton diatoms occur in the greatest quantity in spring, that is, are reproducing at the fastest rate, but some attain their maxima in summer and autumn. A remarkable fact is that some forms have a double maximum, one in spring and one in autumn. In Lake Windermere the following are known to exhibit this phenomenon

No 3261, Vol. 129]

*Asterionella gracillima*, *Rhizosolenia morsa*, and others. The maxima in the spring may be explained by light influencing reproduction, whereas other maxima may be due to differences in temperature and percentage of dissolved salts. Although a difficult task, observation of diatom and plankton maxima in the ocean might lead to interesting results.

Diatoms, of course, must be under the influence of the sun's light and heat to be able to continue their nutritive functions, and so maintain life within the cell. Sunlight is, therefore, a necessity for nutrition, but this is not the case where reproduction is concerned, for it is a notable fact that cell-division (the usual method of reproduction) generally occurs at night. From this it appears that diatom reproduction is probably influenced by the lunar factor, mentioned in Mr Cunningham's letter. If this is so, it would be of great interest to place a culture of diatoms at the optimum temperature in polarised light. Observations of the effect on their cycle of reproduction, and on their prolificacy under these conditions, should prove a very useful piece of research work.

#### Climate and Parent Material in Soil Formation in South-West England

STUDIES of the profiles of soils in central Somerset have shown that typical podsoles are developed on sands, whilst on the Lower Lias limestones and clays adjoining, the profiles are typical of the 'brown earths' described by Ramann<sup>1</sup>. The podsoles are developed on recent deposits—Burtle Beds—and show very clear demarcation into bleached layer and layer of accumulation. The formation from these recent deposits gives us a maximum time for the formation of these podsoles.

Whether podsoles would ever develop on the clays and limestones of the Lower Lias it is difficult to say, because of the disappearance of all the old forest, but they are not found on the present woodland, which may represent the remains of the indigenous forest.

These observations suggest that the climate is such that podsoles would develop with suitable parent material, but on the limestones and clays of the Lower Lias, the parent material is a dominant factor in the soil-forming processes on these deposits in south-west England, the climatic factor being recessive.

#### Protection of Herbarium Specimens

THE letter from Messrs F. K. Jackson and R. L. M. Ghose<sup>1</sup> on the protection of herbarium specimens makes a valuable suggestion. Perhaps I may be permitted to refer readers and others interested in the subject to a paper on the "Preservation of Herbarium Specimens and Insects on Celluloid", by Mr John Ritchie, of the Perth Museum, published in the *Museums Journal* for May 1930. If Mr Ritchie's method of mounting on a transparent sheet of celluloid were combined with the cellophane covering employed by your correspondents, the plant would not only be protected, but would also be visible from both sides.

## Research Items

**The Lime, Rice-Straw, and Convolvulus in India**—Magical and other practices in India in which the lime rice-straw, and the convolvulus play a part are discussed by Mr R. E. Enthoven in *Folklore*, vol 43, pt 1. It is customary for village officials to offer two or three limes to a British official when he visits their district. This is more than a compliment, it is a widespread use in driving away evil influences. A lime stuck on the end of a knife is a well-known spirit-scarrer. Recently its use in connexion with the Bombay rite of *muh mārana* has been noted. The exorcist prepares an image of wheat flour and worships it. A lime pierced by a number of thorns or pins is placed before it, and as water mixed with molasses is poured over the face of the image, the lime gradually fades away. It goes to the man whom it is desired to kill and strikes him in the chest. He falls to the ground vomiting blood. In the Central Provinces, it has been noted of late by police officials investigating cases of suspicious death, that a lime is frequently found by the body, especially where poison is suspected. Rice-straw tied in a bundle to an object, in the Rathnagiri district, prevents interference with it when it is the subject of a legal dispute. From this spell release can be obtained only by an appeal to the deity, who must grant a sign of his decision on the matter. The interest of the convolvulus lies in the fact of its close connexion with certain of the castes of the Deccan and Konkan. Although they differ in occupation and widely in social status, these castes have the convolvulus as their common *devak*, that is, an object of worship, which they must protect. It is a bar to marriage between all members of these castes.

**West Indian Prehistoric Pottery**—A study of the prehistoric aboriginal pottery of the Dominican Republic, Haiti (*Bull* 156, *U S National Museum*), by Mr Herbert W. Krieger, is based largely on examples collected from sites excavated during expeditions to the island in 1928, 1929, and 1930. It was found that variation in decorative design, form, and style was much greater than had been anticipated. Forms and designs, which appeared to be examples of ready-made borrowing, proved to be parts of series linking up with characteristic Taino designs of the Santo Domingo-Porto Rican pottery area. This, in turn, was found to extend well beyond the limits of the two islands, and to link up on the south with lowland forest areas of South America, and on the north with the margin of the eastern Indian pottery area, including the Iroquois of eastern Canada and the contiguous United States. Other designs occur in representative collections from the Upper Mississippi Valley, from the Gulf States of the south-east, and from the Florida Peninsula. This, however, does not imply cultural diffusion or conscious copying, but rather a marginal position in relation to some eastern pottery-producing centre. The entire Mexican, Middle American, lowland and highland South American pottery-producing areas share a common heritage in a culture complex which centres around the cultivation of maize, cassava, and other roots, with which is associated pottery-making. The development of the elements in pottery-making is determined by local environmental differences, physical and spiritual. Thus, for example, in Santo Domingo, the modelling and application of clay figurines, distinctive of decorative design in Middle American tribes, is further differentiated by the absence or presence in representation of certain reptiles and mammals, absent or present in the fauna of that area.

**Individuality of Chromosomes**—During the interphase of nuclear division, the chromosomes usually lose their visible identity, but considerable evidence suggests that they do retain some kind of individuality during this period. It is, however, not clear exactly how we should apply the term individuality. Does it apply only to the chromatic material or should it include the achromatic substratum as well? Bearing on this question, Grégoire (*Bull. Roy. Acad. Sci. Brussels*, 17, 1435-1448) has published an interesting note on some work carried out by one of his students on nuclei of *Impatiens Balsamine*, in which type prochromosomes or euchromocentres are characteristic features of the interphase nuclei. In number, these chromatic bodies are equal to or fewer than the specific chromosome number and occur close to the nuclear membrane, and it is an interesting new point that each one already shows the constriction or point at which the chromosomes will afterwards become attached to the spindle fibres. Another new observation is that during early prophase, bands of achromatic material gradually become evident as prolongations of the euchromocentres. This suggests that not only does the central part of the chromosome persist through interphase as the euchromocentre, but also that this is associated with a definite region of achromatic material which condenses again during prophase into the chromosomes. Though these observations are specific, the uniformity of nuclear behaviour is such that a point definitely shown for types with euchromocentres will in all probability be applicable also in general principle to types with a more uniform nuclear reticulum in the interphase.

**Leaf Curl Disease of Cotton**—A recent paper upon "The Leaf Curl Disease of Cotton in the Sudan" (*Empire Cotton Grow. Rev.*, vol 9, no 1, Jan 1932, pp 32-45), by R. E. Massey and F. W. Andrews, describes a malady of cotton which appears to have general relations with a plant virus disease. The authors correctly use the term 'virus' very infrequently in their paper, as they have no evidence for the ultra-microscopic nature of the causal agent. Their work is nevertheless extensive, and detailed descriptions of symptoms, both external and histological, are given, with descriptions of transmission by insects, grafting, and juice inoculations. It is interesting to note that the lamina of a diseased leaf is more than three times as thick as that of a healthy leaf. The insect vector is apparently an aleurodid, and seems to be an efficient transmitting agent. Grafting is the only other successful method of transfer, for juice inoculations have proved unsuccessful. Chemical examination of healthy and diseased leaves showed no difference in the amounts of starch, pentosans and nitrogen, but revealed a striking increase in diastatic activity in diseased tissue. The curl disease reduces the number of bolls per plant, and so would seem to be of considerable economic importance.

**Meteorological Tables**—The Smithsonian Meteorological Tables, that fill an entire volume of the Smithsonian Miscellaneous Collections (vol 86 in the case of the revised edition under review), are of importance for all serious students and advanced workers in meteorology. These tables were badly in need of revision, the dates of previous editions were 1893, 1896, 1897, 1907, and 1918, and the long interval since 1918 has seen a rapid development of meteorological theory. In an abstract dealing with the new

edition issued by the Smithsonian Institution attention is directed to the more important features that appear for the first time. These include comparisons between sunlight, moonlight, and starlight, standards for the duration of astronomical and civil twilight, comparisons between linear metres and the dynamic metres of V. Bjerknes for variations of gravity with varying latitude and altitude, and tables for the determination of height by observation of the temperature of boiling water. The simpler conversion tables, such as inches to millibars, have not been crowded out. English meteorologists will be grateful for the inclusion of hygrometrical tables appropriate to British wet bulb thermometry. Another particularly useful item, and one not normally included in British publications, is the detailed relationship between the zenith distance of the sun and the mass of air traversed by the sun's rays in reaching the earth's surface. One serious omission may be noted. There are no tables relating to the calculation of the entropy, potential temperature, or pseudo-potential temperature of the air under different conditions of pressure and temperature. The preparation of these tables was done under the direction of C. F. Marvin, chief of the U.S. Weather Bureau, assisted by H. H. Kimball, senior meteorologist of that bureau.

**A Simple Thermo-electric Pile**—M. Jean Gabreau has described the method used on the Chemin de Fer du Nord to notify at a distant cabin the failure of the light on a signal-post (*Bull. Soc. d'Encourag. l'Indust. nat.*, January). It is based on the action of a thermopile which is placed in the lantern above the flame in such a way that the hot air from the flame surrounds one set of junctions while the other set is exposed to the air outside the lantern. The current produced operates a relay in the cabin, which shows a red light and rings a bell when the thermocurrent fails. The thermopiles, which have been in use since 1926, are made by winding forty turns of 0.2 mm. constantan wire around a sheet of mica with notched edges. The wire on one side of the sheet is then varnished and the sheet immersed in acid until the wire on the other side is reduced to half its original section. A thin layer of copper and over it a thicker one of silver, which brings up the section to its original value, are deposited electrolytically. After dissolving the varnish, the whole wire receives a thin deposit of platinum. In action the pile gives an electromotive force of about 400 millivolts, and a current of 4 to 5 milliamperes.

**Infra-Red Photography of Aurora**—Supplementing his communication to NATURE of March 26 on spectrographic observations of infra-red lines in the auroral spectrum, Prof. L. Vegard informs us that Dr. Bauer, working on cinematographic exposures of northlight at the Auroral Observatory at Tromsø, succeeded in January of this year in obtaining a picture of an aurora with infra-red filter and plates sensitive to infra-red rays.

**Cosmic Rays**—Some investigations on the cosmic rays, reported in the first February number of the *Physical Review*, are of particular interest at present in view of the possibility that these may be identical with neutrons. One by H. L. Mott-Smith confirms the failure of other investigators to deflect the rays by magnetic fields, a fine technique has been developed for this piece of work, which includes the preparation of sealed Geiger-Müller counters by good vacuum methods, a refinement which has been repaid by the reliability of the instruments. The main result of the two others, which are by R. A. Millikan,

is that the ionisation of the air by cosmic rays is more intense than had been supposed, the rate of formation of ions at sea-level under standard conditions is now given as almost 2.5 per c.c. per second instead of about three-fifths of this. Prof. Millikan has also found that the sun has no direct influence on cosmic ray intensities, to within about  $\frac{1}{3}$  per cent of the total ionisation, and has shown incidentally that there is an interesting source of error in connexion with the use of electrosopes containing gas at high pressure for precision work, arising from the effect of temperature on the rate of recombination of ions.

**Elements 85 and 87**—Allison, Bishop, Sommer, and Christensen (*J. Amer. Chem. Soc.*, Feb.) describe experiments with a magneto-optical method, depending on the time lag differences of the Faraday effect behind the magnetic field, on solutions of minerals. In solutions of pollucite and lepidolite, minima were observed which cannot be due to tin and rhenium compounds, and are attributed to element 87. This is also stated to exist in sea water, Searles Lake brine, Stassfurt kainite, crude caesium chloride, monazite sand, and samarskite. Six minima are considered to indicate the probable existence of six isotopes of element 87. Element 85, present only in very small amounts, was detected in solutions of Brazilian monazite sand, from 100 lb. of which indications of  $2.5 \times 10^{-6}$  gm. of the lithium compound of 85 were obtained. The name alabamine (Am) is proposed for the element, and the solutions are supposed to contain salts of the acids  $\text{HAmO}_4$  and  $\text{HAm}$ . The atomic weight of alabamine is estimated to be 221. The peralabamic acid is more stable than other oxy-acids of the element which are indicated in the solutions after appropriate treatment.

**Intermetallic Compounds formed in Mercury**—A. S. Russell, with Cazalet, Irwin, and Lyons (*J. Chem. Soc.*, March) describes the formation in mercury of several stable compounds of the metals copper, tin, zinc, and iron produced by shaking the metals with mercury. These differ from the constituent metals in being insoluble in mercury and generally in reducing power. It was necessary to devise analytical methods for determining their empirical formulæ without removing them from the mercury in which they were suspended, and these methods are described. Some of the compounds are ternary, mercury being one constituent, and their formulæ are very varied, but the total numbers of valency electrons are 6, 9, or 12, or a simple multiple of these numbers. Iron does not form a compound with mercury, yet its action towards reducing agents in presence of mercury resembles closely that of copper, although the passivity does not depend on metallic compound formation. Many of the binary intermetallic compounds have not previously been reported.

**The Glow of Phosphorus**—The *Collection of Czechoslovak Chemical Communications* for March contains an account of the influence of chlorine and bromine on the glow of phosphorus by Krejčí and Schacherl. The inhibiting effect of these halogens on the glow had been previously noted, and the case of chlorine studied in detail by Bowen and Cavell in 1929. The present authors took special precautions to ensure the purity of the materials, the chlorine, for example, being obtained by the electrolysis of fused pure silver chloride. The pressure in the apparatus was followed by a Bodenstein quartz manometer, the effect on the glow in air and oxygen at temperatures of 15°, 20°, and 25° C. being investigated. Both halogens show a poisoning effect, which is

stronger in oxygen than in air. They are more effective than ethylene but weaker than propylene, whilst nitrogen dioxide, previously investigated, is about ten times as efficient as either. The results could be represented by the equation already used for nitrogen dioxide, namely,  $p = k/(a + x)$ , where  $x$  is pressure of halogen/pressure of oxygen,  $p$  is the maximum pressure of the glow, and  $a$  and  $k$  are constants. Dry gases were used. The effect can be explained on the assumption that chlorine breaks reaction chains by forming chlorine monoxide with atomic oxygen.

**Deterioration of Structures in Sea Water**—The Committee of the Institution of Civil Engineers which is investigating the deterioration of structures of metal, timber, and concrete in sea water, began its work in 1916 and published its first report in 1920. Interim Reports have been issued annually since then, and the twelfth of the series reviews the work done in 1930–31 (London: H.M. Stationery Office, 6d net). The specimens under observation are exposed in many parts of the world—Nova Scotia, Ceylon, Australia, New Zealand, Kenya Colony, the Gold Coast, etc.—and the materials exposed include many varieties of iron and steel, many kinds of timber, and specimens of ferroconcrete. Of the various irons and steels under observation, those with the highest percentage of nickel and chromium appear to give the best results. The investigations of the Committee on methods of protecting timber against marine borers have been continued with the assistance of Profs G. Barger and S. M. Dixon, and in his report Prof. Barger gives the results obtained through impregnating timber with creosote, fuel oil, arsenical poisons, naphthalene, or tar acids. Prof. Dixon, in a further report, gives some interesting figures showing the effects of incising timber before impregnation. A block of Oregon pine (Douglas fir), 10 in.  $\times$  6 in.  $\times$  2 ft., with incisions

spaced  $\frac{1}{2}$  in. apart in rows round the periphery absorbed two to three times as much creosote as a similar unincised block.

**Breaking Circuits and Clearing Faults on Large Networks**—The modern methods of linking together isolated electric distribution networks has given rise to problems in mathematics and physics, partial solutions of which are now being obtained. All the component networks are linked into a single network, every part of which responds to changes in every other part. The large amount of generating plant working in parallel distributed over a wide area, and its haphazard distribution, have introduced problems which do not occur in small networks. In a paper read to the Institution of Electrical Engineers on March 17, R. O. Kapp and C. G. Carrothers discuss from the mathematical point of view the design of systems to protect the network when a fault occurs. It is suggested that the fluctuations in the currents caused by a fault might be used to work the relays employed for the automatic isolation of a faulty portion of the network. At the same meeting H. Pearce and T. T. Evans read a paper on the design and performance of oil circuit-breakers, that is, switches which break the electric circuit under oil. The irregularity in the performance of these devices is generally considered to be due to the erratic movement of the oil. For the higher voltages, quick-break apparatus is considered advantageous. By suitably designing the two contacts with a shroud, improved and consistent results are obtained. The importance of short circuit testing is emphasised, and a plea is made for facilities for testing on the site. A description is given of the oscillograph equipment necessary for testing on the site, and reports of recent tests carried out on oil circuit-breakers fitted with a new type of shrouded contact are added.

## Astronomical Topics

**Parallaxes of Faint Stars**—Study of pairs of photographs taken at intervals of several years have revealed many examples of very faint stars with fairly rapid proper motions. *Mount Wilson Contributions*, No. 435, contains a paper by A. Van Maanen on an investigation of the parallaxes of some of these stars from photographs taken with the 100-inch and 60-inch reflectors. The largest parallax on the list is that of B.D. 43°4305, for which the value 0.209" was found. That star had, however, already been measured elsewhere. Another large parallax is that of Ross 41, mag. 13.4, parallax 0.110". Altogether there are 15 stars on the published list that have absolute magnitude fainter than 10.0. The faintest is a star lately found by Hubble to have a proper motion of more than 1", its absolute magnitude is 14.0. The fact that such a large number of extreme dwarfs are found comparatively near the sun shows that this type of star must really be very common in space, but they are too faint for observation unless their distance is small.

**Astronomical Notes for May**—Venus continues to be a brilliant object, reaching its greatest brilliance on May 22, the illuminated fraction of the disc diminishes during the month from  $\frac{1}{2}$  to  $\frac{1}{4}$ , it is near the moon at 5 P.M. on May 9.

Jupiter passes quadrature with the sun, and is still observable for half the night. Satellites I and II and their shadows are both on the disc on the evening of May 5, I and IV are simultaneously in eclipse late on the evening of May 20, there is a partial eclipse

of III by the shadow of II on May 4 from 11.16 to 11.38 P.M.

Saturn can be observed late in the night, but its south declination of 19° renders the conditions difficult.

$\alpha$  Virginis is occulted by the moon at 8.5 P.M. on May 17, it is the only occultation visible in London before midnight.

Two comets may be visible with moderate telescopes, the following ephemeris of Houghton's comet for 0<sup>h</sup> is by Drs. Cunningham and Whipple, an ephemeris given earlier proved to be erroneous.

|       | R.A.                                            | Decl.     |
|-------|-------------------------------------------------|-----------|

| May 15 | 7 <sup>h</sup> 54 <sup>m</sup> 12 <sup>s</sup> | 20° 23' |
| " 20   | 8 20 20                                        | 26 0    |
| " 25   | 8 53 28                                        | 32 32   |
| " 30   | 9 37 24                                        | 39 39   |

Ephemerides of three other periodic comets, Neujmin (2), Kopff, and Borrelly, are given in the *B.A.A. Handbook for 1932*, all are likely to be near the tabular positions, the search for them will be most conveniently made by photography.

The times given above are Greenwich Mean Time; 1 hr. should be added to give Summer Time.

## Physiological Studies of Single Plant Cells

PHYSIOLOGISTS will welcome a summary ("Physiological Studies of Single Plant Cells", by W J V Osterhout, *Biological Reviews*, vol 6, pp 369-411) of the extensive literature on the algae *Valonia* and *Nitella* by one who has been so intimately associated with this work. The bibliography is a formidable one comprising 227 citations. The data obtained by three types of experimental procedure, namely, (1) chemical analysis, (2) measurement of potential differences at various boundary surfaces by the use of single cells suitably arranged to procure the desired electrical circuit, (3) measurement of electrical resistance or capacitance, are discussed.

The review is itself so condensed that any further summary of it would be impracticable. The electrical experiments are interpreted as supporting the idea that the external cell surfaces are non-aqueous in nature, of high resistance, and permitting little dissociation of salts. The relative order of the mobilities of ions in protoplasm (unlike the case of collodion) does not resemble that obtained for salts in water, but rather that for certain non-aqueous solvents. In spite of the discussion and the literature cited there will still be, no doubt, those who find it difficult to conclude that some of the theories advanced materially clarify the vexed question of the accumulation of electrolytes by living cells. It is a question whether (for example, in the case of the accumulation of KCl) the facts warrant the more complicated assumption that accumulation of KCl involves penetration of undissociated KOH, the energy necessary being furnished by metabolism with the liberation of an organic acid HA which is then exchanged for HCl of the external solution (see p 377), rather than the simple statement that KCl accumulates against a concentration gradient, the energy necessary being

supplied by metabolism. In this connexion the comprehensive experiments of Hoagland and Davis receive but incidental citation.

It seems curious that, whilst in certain connexions stress is laid upon the importance of the energy released by the cell and that salt accumulation is not a physico-chemical equilibrium, the multiple partition theory of Irwin should receive such favourable discussion, whilst the mathematical treatment seems to evade such energy supply and to involve mainly operations based on equilibria. It is possible that some of the interpretations of accumulation which apply solely to electrolytes, and not at all to non-electrolytes, may be premature, whilst the view that the cell has at its disposal a source of energy which may produce accumulation of both electrolytes and non-electrolytes seems to have been rather lightly dismissed, though it has figured somewhat prominently in other writings upon *Nitella*.

Many will reiterate one of the concluding remarks: "But mere complexity should not baffle the analytical resources of modern science if all the variables can be measured. The greatest difficulty is that in attempting measurements we may change variables or create new ones without being aware of it." The necessarily scanty attention paid to experimental technique in so brief a review covering so wide a field leaves one unable to say to what extent many of the experiments were affected by such uncontrolled variables. In particular, the effect of the often arbitrary technique adopted on two of the most important variables when dealing with respiring plant cells, namely, the oxygen and carbon dioxide concentrations in the environment, with its consequent effect on metabolism and any processes determined by metabolism, remains difficult for the reader to evaluate.

## Meteorology of the Persian Gulf and Mekran

UNTIL after an international aerial route had been established along the Persian coast, meteorological information for this region was very scanty; the systematic study of its climate rested mainly upon a few observing stations, making observations once a day only, which had been established by the India Meteorological Department. A more elaborate organisation arose in 1927, in response to the needs of aviation, which took the form of a chain of telegraphic reporting stations extending from Karachi to Bushire and observing at 4 A.M. and 2 P.M. G.M.T., that is to say, at about 8 A.M. and 6 P.M. local mean time.

The records obtained in this way allowed of the construction of synoptic weather charts on modern lines, each station, moreover, kept a diary of phenomena occurring in disturbed weather. It is usually considered necessary to have records over a long period of years for any region before attempting to discuss its climate. To obtain reliable 'normal' values for the different climatic elements, this is a real necessity, but a careful perusal of Dr Banerji's recent publication\* suggests that he has done a useful service by presenting a preliminary study, which appears to give the salient climatic features of an interesting region, and connects these with meteorological events over a wide region extending to the Asiatic 'centre of action' in the north and to the

south-east trade-winds of the southern part of the Indian Ocean.

As would be expected from geographical considerations, the climate of Mekran and the Persian Gulf has many points of resemblance with the better known climates of north-west India. There is a winter regime and a summer regime, and the differences between the two greatly transcend those that must inevitably arise through seasonal variations in the amount of solar radiation and in the length of the day. The explanation obviously lies in the disturbance set up by the great seasonal change of pressure over Asia, and by the invasion of the Indian area in summer by diverted south-east trades from beyond the equator, that cause the Indian 'rams'.

In winter, the Asiatic area of high pressure tends to show an extension south-westwards to Persia, but the fine and dry weather that might result from this is interrupted by the eastward passage of depressions known to Indian meteorologists as 'western depressions'. About eight of these occur on an average in a winter month. Dr Banerji found, as a result of a careful analysis of his synoptic charts, that these are generally the remains of depressions that have passed out of the eastern Mediterranean, or secondary disturbances connected with them, such as are frequently found to occur when a depression crosses mountainous regions or is nearing the end of its life-history. Their behaviour and mode of formation are considered by him to conform with Norwegian views as to the origin of the depressions of temperate latitudes.

\* India Meteorological Department. *Meteorology of the Persian Gulf and Mekran*. By Dr B N Banerji. Pp. iii+65+9 plates. (Calcutta: Government of India Central Publication Branch, 1931.) 3 rupees, 5s. 3d.

All the phenomena of the warm and cold 'front' and of the 'warm sector' are observed. In the cold front, the phenomenon of the line-squall, with or without thunderstorms, is often well developed, and is a danger to aerial navigation, for the northerly or north-westerly wind may arise with the force of a gale. There is little doubt that the outflow of cold air from the Siberian high-pressure area tends, owing to the general configuration of the land around the Persian Gulf, to take a north-west to south-east trend from Iraq, and it readily concentrates into a violent intruding wave of polar air behind a depression. An analogous effect is to be observed in the lower reaches of the Rhone valley, where we have the violent 'mistral'. As the western depressions of the Persian Gulf often advance from regions lacking in meteorological reporting stations, the onset of the dangerous cold front squalls can only be anticipated well in advance from the other frontal phenomena and pressure changes that normally precede it, which does not allow of accurate anticipation of the time of its arrival. Owing, however, to the fact that the ocean swell to which it gives rise travels more rapidly than the front itself, an 'eleventh hour' warning of a much more definite kind is obtained from the arrival in suitable circumstances of such a swell.

In summer, conditions are more complex and less definite. The Asiatic low-pressure system has a local extension south-westwards to Arabia, and variations in the intensity and position of the centre of this extension, which is often to be found over the south-east of Arabia, are liable to cause big changes of wind and weather over the Gulf and Mekran. When the local centre retreats to Persia or north-west India, north-westerly winds tend to invade the whole region, and may reach the force of a gale, but they

will do so only gradually, and violent frontal squalls need not be feared at this season. At the height of the monsoon, when south-west winds have advanced across the Arabian Sea so as to penetrate Persia and Baluchistan, depressions may travel into those countries and winds from south-west or west may extend from Mekran over at least a part of the Gulf. Occasionally also depressions moving westwards from the Bay of Bengal affect this area. More often at this season there is a cyclonic circulation around the south-east of Arabia, the wind being southerly to easterly in Mekran and north-westerly in the Gulf.

Between the winter and summer regimes there are transitional periods, when, apart from local thunderstorms, dust storms, and other disturbances of convectional character, the weather is for the most part fine and quiet.

The effects of the various seasonal tendencies, outlined above, can be traced in the climatic tables towards the end of the work, and some individual storms are illustrated by synoptic charts and records of autographic instruments. Apart from its practical importance for flying, the work links up the better known climates of north-west India, Mesopotamia, and Upper Egypt in an instructive manner. Considered simply as climate, the heat and small amount of cloud revealed by the tables are the outstanding features of this region. Shade temperatures above 90° begin to appear so early as February, and 100° is often exceeded from March to October. In July, nearly all the stations have a mean night minimum above 80°, while at Bushire it averages 87°. Within the short period under review, 112° has been attained in more than one place. It must not be supposed that dry healthy heat is the rule, for, at the entrance to the Gulf, the wet bulb thermometer averages 85° in July.

E. V. N.

### The Origin of 'Mare Sporco'

MASSES of a yellowish or greenish-brown gelatinous substance floating at the surface of the sea and at times colouring large areas are the cause of the phenomenon known as 'mare sporco'. It is especially noticeable in the Adriatic, but may occur also in many other places. Numerous authorities have written on the subject, and Dr Vito Zanon has reviewed the literature in the paper before us ("Esame di un campione di 'Mare Sporco' del Golfo di Fiume" *Memorie della Pont. Accademia delle scienze—i nuovi Lincei* Series 2, vol 15 1931). His conclusions, based on his own observations, show that these curious masses in the water have their origin at the bottom where innumerable diatoms, usually a few definite bottom-living species, in certain circumstances by rapid reproduction give rise to a large amount of a gelatinous substance impregnated with much oxygen.

When the water is warm the bubbles of gas swell and the gelatinous masses, which are full of diatoms, and with them a good deal of oozy mud, rise to the surface, causing the water to appear a dirty yellowish or greenish colour. When it is colder, or when storms, winds, and waves are in action, the masses are scattered and descend again to the bottom. Great inconveni-

ence is caused to the fishing nets, as the masses clog the meshes and sometimes break them with their weight. This condition may last a fortnight, during which time fishing may have to be abandoned.

The special sample from the Gulf of Fiume examined by Dr Zanon was made up chiefly of the diatoms *Nitzschia Lorenziana* var. *subtilis* Gran, *Pleurosigma lineare* Gran, and probably *Nitzschia sigmoides* W. Sm., but different diatoms may be the cause in other parts. Some authors found dinoflagellates and various planktonic forms. These, however, may have become entangled in the floating gelatinous mass and may not be its original cause. Schreiber found chiefly the diatom *Bacillaria paradoxa*, which lives epiphytically on *Zostera*, in the masses from the waters around Venice.

Dr Zanon shows clearly that the phenomenon is not identical with those efflorescences in the sea which among many names given to them are known as 'red water' or 'yellow water'. These are caused by an enormous outburst of growth of certain planktonic organisms. The true 'mare sporco' is definitely caused by bottom diatoms in gelatinous masses, rising to the surface in the warmth and descending in the cold.

### Ceremonial Games and Social Organisation among the Creek Indians

MR JOHN R. SWANTON during the summer of 1929 visited the Creek country with the view of obtaining further information relating to the 'square grounds' or sacred areas in which the Creek Indians celebrate their busks and other annual ceremonies. His report is now published in *Smithsonian*

*Miscellaneous Collections*, vol 85, No 8. The 'square grounds' are intimately connected with Creek ceremonial, social and political organisation. According to tradition, after the formation of the Creek confederacy, the Kasihta and Coweta, the two divisions of the Muskogee element in the Lower Creeks, who

lived on the river, now the boundary between Alabama and Georgia, having defeated all their enemies, instituted periodical ball-games as a kind of moral equivalent for war. As friendly relations were established with other Indians and they were admitted to the confederacy, they joined with one side or the other and the dual system became general, the Kasihta becoming known as the 'white' side and the Coweta as the 'red'.

In the ceremonial games four towns played on either side. There was a certain aloofness of the towns of one moiety from those of the other. They did not intermarry. The people of each town were divided into clans, each with an animal name, and certain of these clans were linked into phratries which, in theory at least, were exogamous. A further division links them as 'white' people and 'people of a different speech'. These are also said to be exogamous, but the principal function of this division seems to be to determine on which side the people should play in the town games.

Every town has a ceremonial ground in which there are three elements: a community hot-house, used in bad weather and for secret ceremonies, a 'square ground', and a 'chunky yard', so called from an old pastime which consisted in rolling a disc along a level plot and throwing poles at it. In the centre of this yard is a single pole with a cow, a horse skull, or a wooden figure on it. Around this the men and women play a kind of ball-game.

In the ceremonial games, which resemble our lacrosse, and are solemn affairs, only the men play. On the 'square ground' are performed the 'stomp-dances', of which three or four take place in the spring and early summer. Only members of the town take part. They lead up to the great annual ritual, lasting four days, in which prominent features are the woman's dance and the fast and ceremonial bath of the men. This is a ceremony by which the Creeks clearly believe that they return to the state of harmony with the spirit of Nature which has been ruptured by the profane acts of the preceding year.

### University and Educational Intelligence

CAMBRIDGE—An appointment is to be made this year to a Busk studentship in aeronautics. The studentship is of the value of about £150, tenable for one year, and is open to any man or woman being a British subject and of British descent who has not attained the age of twenty-five years on Oct. 1 next. Forms of application for the studentship can be obtained from Prof. B. Melville Jones, Engineering Laboratory, Cambridge, and must be filled up and returned to him not later than May 12.

Prof. Albert Einstein will deliver the lecture on Mr. Rouse Ball's Foundation on Friday, May 6, at noon. The subject of the lecture will be "Die Theorie der Elektrizität im Rahmen der allgemeinen Relativitätstheorie."

LONDON—Applications are invited for the Bayliss-Stirling Memorial Scholarship (value about £120 per annum and exemption from tuition fees) at University College. The successful candidate will be required to follow a course of study approved by the Jodrell professor of physiology and involving a training in the principle of and methods of research in physiology and biochemistry. Applications must be received not later than May 14 by the Secretary, University College, Gower Street, W.C.1.

MANCHESTER—The Manchester City Council is again offering a number of scholarships tenable in the Faculty of Technology of the University. Suc-

cessful candidates are required to follow a full-time course leading to the degree of bachelor of technical science in the College of Technology, and matriculation or its equivalent is an essential qualification. For students who have been engaged in industry, and who have attended part-time day or evening classes, the scholarships are of the value of £100 a year, while for students leaving secondary or central schools the value is £60.

### Calendar of Geographical Exploration

#### May 1, 1607—Hudson's Voyages

Henry Hudson left Gravesend on his first voyage of arctic exploration, hoping that it might be possible to find a passage right across the polar area. He sighted the east coast of Greenland north of any previous point reached, and by following the ice barrier which extends between Greenland and Spitzbergen, proved that there was little chance of finding a passage through. On a second voyage he reached Novaya Zemlya and made several landings, but failed to penetrate to the Kara Sea. In his next voyage (1609), the ice proving unfavourable for the Novaya Zemlya region, he decided to search for a passage on the American coast, and there discovered the Hudson river. In 1610 he set out in the *Discovery* and passed through Hudson Strait to Hudson Bay. In the latter the ship was frozen in, and the party passed the winter in great distress and scarcity of food. A mutiny broke out, and Hudson and those who supported him were put in an open boat and left to their fate, the mutineers sailing home in the *Discovery*. The strait and bay named after him were probably known to the Portuguese in the second half of the sixteenth century, and Frobisher and Davis also visited the strait.

#### May 1, 1769—Opening up Kentucky

Daniel Boone, a typical backwoodsman, keen on hunting and exploration, left his home in North Carolina, crossed the Alleghenies and the Cumberland Mountains, and reached the fertile but forest-clad plain of Kentucky. He was captured by Indians, but made his escape, and later settled with his family in the region, which was soon visited by other surveying parties.

#### May 2, 1497—John Cabot

The *Matthew*, commanded by John Cabot, a Genoese who became a naturalised citizen of Venice and later settled in England, sailed from Bristol. With a crew of 18 he crossed the North Atlantic and discovered land thought by some to be Cape Breton Island, by others to be southern Labrador or Newfoundland or Nova Scotia. In any event, Cabot did not realise that he had approached the shores of America, but thought that the land was part of the coast of north-east Asia. His son, Sebastian, after sailing in a Spanish expedition from Seville which reached the river La Plata in 1527, returned to England. He afterwards became director of the Company of Merchant Venturers, incorporated on Dec. 18, 1551, and in that capacity helped to organise the expedition of Willoughby and Chancellor.

#### May 3, 1850—Sledge Travel in the Arctic

Capt. H. Austin sailed with two ships to search for Sir John Franklin via the Barrow Strait. Austin and Penny, a whaling captain, entered Barrow Strait and discovered Franklin's winter quarters of 1845-46, but no record of the direction taken by the ships. Austin and McClintock advanced to Melville Island, marching more than 770 miles in 80 days. Austin also examined the entrance to Jones Sound. The expedition is

notable for the excellent way in which M'Clintock conducted the sledge travelling. M'Clintock went out again with Kellet's expedition, which passed the winter of 1852-53 at Melville Island. M'Clintock travelled with a sledge party for 105 days, covering 1328 miles, Meham and Vesey Hamilton travelling for 94 and 97 days respectively. They completed the exploration of the north and west of Melville Island and of the coast-line of Prince Patrick Island.

#### May 5, 1255 — An Early Journey to Mongolia

William of Rubruck, or Rubruquis, reached Cilicia after his journey to the court of the Grand Khan. He was sent by Louis IX. of France as an envoy and left Acre in 1252. He went by sea to Constantinople, whence he sailed in May 1253 to the Crimea. He travelled by land to the Talas valley, penetrated to Lake Balkhash, passed the Ala Kul, entered Mongolia, and arrived at the court of the Khan on Dec. 25, later accompanying the court to the Karakoram. His narrative supplemented that of John de Plano Carpini, 1245-47. He gives interesting descriptions of the salt trade via the Don, and notes that the Caspian Sea is an inland sea and not a bay of the ocean, as was then believed.

#### May 6, 1788 — The Marshall and Gilbert Islands

Capt. Marshall left Port Jackson and was later joined by Capt. Gilbert, the two ships keeping together for most of the voyage. After passing Norfolk Island and sighting Matthew's Island in  $22^{\circ} 22' S$ ,  $170^{\circ} 41' E$ , the two captains navigated the little-known part of the Pacific in which they discovered the groups of islands which now bear their names.

### Societies and Academies

#### LONDON

Royal Society, April 21 — H. W. McKenny Hughes. Induced melanism in Lepidoptera. Females of the Geometrid moth *Selenia bilunaria*, Esper, were collected in three different areas in southern and eastern England, as far as possible away from industrial areas. Two generations were fed upon pure untreated hawthorn, after which four subsequent generations were fed upon hawthorn treated with lead and manganese salts respectively. Brother and sister matings were adopted throughout the experiment. Adequate control broods were kept, and in all 3265 moths were reared. No melanic individuals appeared at any time, either in the control or treated broods — S. Adler and O. Theodor. Investigations on Mediterranean kala azar (6). Canine visceral leishmaniasis. Eleven out of 100 dogs examined in Malta between June and November were found to be naturally infected with kala azar. Seborrhea and partial depilation are the most frequent signs of canine kala azar and were found in nine out of eleven cases. The skin condition is due to infiltration of macrophages round hair follicles. Infected macrophages are found throughout all parts of the skin, both in the areas of infiltration round the hair follicles and in normal dermis. Sandflies, *P. perniciosus*, were infected with *Leishmania* by feeding on the unbroken skin of three dogs. The infection rates were 62.5 per cent, 65.4 per cent, and 32 per cent respectively — R. H. Stoughton. The morphology and cytology of *Bacterium malaccarum*, E. F. S. (2). Reproduction and cell-fusion. New morphological forms have been observed. The production of coccoid bodies, their liberation, and subsequent germination to form apparently normal rods, is described. The formation of densely-staining spherical bodies, apparently arising

from the point of fusion of two cells, is described. These bodies are apparently liberated by the degeneration of the parent cell.

#### PARIS

Academy of Sciences, March 14 — Ernest Esclançon. Talking clocks designed for the telephonic distribution of the time. Two types of apparatus are described, both depending on the use of a photoelectric cell with amplifiers. It is proposed to instal these at the Paris Observatory for telephonic distribution of time through the Post Office — A. Cotton and H. Mouton. The optical properties of a thin layer of nitrobenzene submitted to electrostatic stress. A thin layer of nitrobenzene, submitted to alternating current (1000 to 2500 volts), shows double refraction. It differs from the Kerr effect in that the double refraction develops slowly (2-3 minutes) and takes a similar time to disappear after suppression of the field — L. Cayeux. The interpretation of the deposits of calcium phosphate dredged on the Agulhas Bank, to the south of the Cape of Good Hope. The Agulhas Bank phosphate deposit is formed of materials foreign to the green sand on which it rests. The nodules of phosphate are derived from deposits formed at greater depths than those where it is now found. The current formation of phosphatic deposits on the sea floor cannot be proved — V. Grignard and J. Colonge. A new general method for the condensation of ketones — Henri Logatu and Louis Maume. Can the leaf accept an excess of mineral food without benefiting the development of the plant? The leaf of the potato can show a marked excess of potash without benefit to the plant — Louis Lapique. The verification of decease by a medico-scientific test clearly proving death with certainty — Jean Cantacuzène was elected *correspondant* for the Section of Medicine and Surgery, and Emile Guyénot *correspondant* for the Section of Anatomy and Zoology — Jean Mascart. Remarks on logarithms — Georges Durand. The application of the conception of contingent to the research on the characters of planicity for a simple arc — S. Mazur and S. Ulam. The isometric transformations of vectorial spaces, *normés* — A. Marchaud. The limiting demisecant and semi-tangents — Karol Borsuk. The conception of local contractibility of ensembles — Edouard Callandreau. The close connexion between Coulomb's and Boussinesq's theories of the thrust of soil — Paul Santo Rini. A high frequency method for the study of vibrations both at the surface and in the interior of a solid, especially the framework of a bridge — Nicolas Kryloff and Nicolas Bogoluboff. Some examples of non-linear vibrations — P. Lambert and J. Lecomte. The infra-red absorption spectra of hydrocarbons with nucleus. Results of the application of the recording spectrometer described in a previous paper to the infra-red absorption of derivatives of cyclohexane, cyclohexene, and naphthalene — R. Freymann and S. Takvorian. The absorption spectra of the rare earths in the infra-red. The spectra were studied in the region  $0.82\mu$ – $1.16\mu$ . Some new absorption bands have been detected, and these are of interest from the point of view of analysis — Maurice Robert. A new method of study and of regulation of a television transmitter — S. Rosenblum and M. Valadares. The fine structure of the  $\alpha$ -rays of thorium-C. Utilising the large electromagnet of the Academy of Sciences, a new faint line ( $\alpha_5$ ) has been detected. The line  $\alpha_4$ , noted as doubtful in an earlier note, is confirmed — P. Reiss. The intervention of equilibria of oxidation-reduction in the permeability of a membrane — W. Broniewski and S. Koslacz. The silver-copper alloys — A. Perret. The action of primary amines on dicyandiamidine sulphate. Under

certain conditions detailed, a primary amine  $R\ NH_2$  reacts with the acid sulphate of dicyandiamidine—giving guanidine sulphate and the symmetrical urea  $CO(NH\ R)_2$ —P Weill and Mlle Madeleine Darmon. The isomerisation of phenylglycide. The affinity capacity of the primary alcohol group—J Bougault and Mlle Pinguet. The combinations of allantoxanic acid and of allantoxidine with the alkaline bisulphites. Crystalline compounds are formed, slightly soluble in water and hence useful from the analytical point of view—R Marcel Godchot and Max Mousseron. The resolution of *o*-aminocyclohexanol into its optical antipodes—Mlle D Biquard. The preparation of the cyanhydrins of the formula  $C_6H_5(CH_2)_n\ CH(OH)\ CN$ ,  $C_6H_5(CH_2)_n\ CH(CH_3)\ CH(OH)\ CN$  and the corresponding  $\alpha$ -acid-alcohols—Ch Courtot and P Chiffert. The aryl thioniums with strictly hydrocarbon radicals—M Battegay and H Silbermann. The aryl ethers of pseudo-urea—J P Arend. The constitution of oolitic minerals and its relation with the facies of the deposits—Andre Demay and Henri Longchambon. The antistephanian tectonic of the Cevennes at the height of Largentiere—Raymond Furon. The extension of the marine Devonian in western Africa—Antonin Lanquine. The dislocations of the secondary strata of the valley of Caramy, below its confluent with the Issole (Var)—L Dubertret, A Keller, and H Vautrin. Contribution to the study of the Syrian desert region—Henri Erhart. The types of soils in the loess district in Alsace—L Cagniard. The reflection of a spherical and isotropic seismic wave at the surface of the soil—L Eble and G Gibault. The values of the magnetic elements at the station of Val-Joyeux (Seine-et-Oise) on Jan 1, 1932—R Hickel. The two layers of tertiary plants in the Bas-Rhin—J Szymanek. Supplementary caryological observations on *Gossypium*—Paul Wintrebert. The preservation in paraffin sections of the vital marks in Bismarck brown and Nile blue, made on the living eggs of Amphibians—A Policard and A Morel. The comparative utilisation of a spark or of an arc in the spectrography of sections (histospectrography)—Maurice Lecamp. Grafts of fragments of the posterior limbs in *Alytes obstetricans*—A Girard, G Sandulesco, A Fridenson, C Gaudefroy, and Ir J J Rutgers. The crystallised sexual hormones extracted from the urine of pregnant mares. Detailed crystallographic study of folliculine and equiline. The composition of the latter is probably  $C_{18}H_{20}O_2$  its physical, chemical, and physiological characters are described. A third crystalline hormone isomeric with equiline (hippuline) has been isolated—Mmes Eudoxie Bachrach and Jeanne Roche. The prolonged action of potassium chloride produces a displacement of the thermal optimum of yeasts—Ph Lasseur, M Pierret, A Dupaux, and C Maguitot. Remarks on the bactericidal power of metallic silver—Michel Faguet. Contribution to the study of microbial multiplication (*Bacterium coli*). The opacity of a broth culture is taken as measuring the number of micro-organisms. The variations in the opacity have been measured and recorded by means of a photoelectric cell. A reproduction of a 12-hour record is given—C. Jonesco-Mihaiesti, D Noica, and B Wisner. The experimental transmission to the ape of a disseminated human encephalomyelitis—G Mouriquand, A Leulier, and Mlle Weill. Age and substances preventing the assimilation of lime.

## LENINGRAD

Academy of Sciences—*Comptes rendus*, No 11, 1931—V. Vernadsky. The field of stability of the liquid carbonic acid in the biosphere. Carbonic acid in liquid form exists in microscopic pores of many

minerals and must play an important part, but the problem has never been studied. Still more important is the fact that the low average temperature of water in oceans, coupled with great pressure in oceanic depths, make the existence in deep waters of liquid carbonic acid a certainty, and this cannot be without an effect on the life of organisms. It is possible, for example, that the absence of planktonic organisms at relatively small depths, where there is still light, is due to peculiar conditions for respiration owing to a certain part of the carbonic acid being in liquid state (see also NATURE, April 23, p 607)—V Chlopin. Geochemistry of noble gases—E Krinov. A bolide meteor of Nov 23, 1930, in the Nizny-Novgorod region. Observations by eye-witnesses are quoted and a sketch-map of its track is presented—A Reichardt. On a new representative of the genus *Philotis*, Rehd. Description of *Philotis atavus*, sp n, from Buchara.

## SYDNEY

Linnean Society of New South Wales, Nov 25—W. W. Froggatt. A classification of the gall-making coccids of the genus *Apiomorpha*. The male and female galls are described and the range of each species, together with the name of the host eucalypt, is given. The species of the genus are classified into groups based on the form and disposition of the hairs and spines on the dorsal surface and the structure of the anal appendages—Ida A Brown. The stratigraphical and structural geology of the Devonian rocks of the south coast of New South Wales. The formations found in the south coast district are correlated with a number of other occurrences of Devonian rocks in south-eastern Australia, and the palaeogeography of the Devonian era is considered—H M R Rupp. Notes on New South Wales orchids. A description is given of a teratological specimen of *Caladenia testacea* from the South Maitland coalfields, and a distinctive form of *Dendrobium teretifolium* var *farfara* is recorded—Gladys Carey. Note on the leaf-buds of *Angophora*. More detailed examination of the leaf bud of species of *Angophora*, previously described by the author as "an ill-defined axillary swelling", shows that this swelling is in reality a deep-seated bud of peculiar type in which the primordia are well differentiated—Lilian R Fraser. An investigation of *Lobelia gibbosa* and *Lobelia dentata*. Mycorrhiza, latex system, and general biology. The root is infected from the first by the fungus, which remains in an intercellular position in the cortex. The fungus infects the younger parts of the root and all lateral roots by growing down from the older region, and goes through a series of changes, being finally almost crushed out by the cortical cells of the root. Reinfestation of roots takes place at intervals from the soil, rhizomorph-like strands of the fungus coming into contact with the root and penetrating into the cortex. The latex system of the two species is briefly described.

## Forthcoming Events

FRIDAY, APRIL 29

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Department, Imperial College of Science and Technology), at 2.30—Dr S G Paine. The Relationship of Micro-organisms to the Decay of Stone—Dr E S Moore. Virus Disease Problems in Tobacco Cultivation in South Africa.

ROYAL ASTRONOMICAL SOCIETY, at 4.30—Geophysical Discussion. The Maintenance of the Earth's Electric Field. To be opened by Dr F J W Whipple, and continued by Dr G C Simpson and others.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7—Dr C V Drysdale Future Progress in Electrical Measuring Instruments (Lecture)  
 ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof H Hartridge The Rival Theories of Hearing

#### MONDAY, MAY 2

ROYAL INSTITUTION OF GREAT BRITAIN, at 5—Annual Meeting  
 UNIVERSITY COLLEGE, LONDON, at 5 15—Prof O Grosser Human and Comparative Placentation, including the Early Stages of Human Development (1) (Succeeding Lectures on May 5 and 6)  
 SCHOOL OF ORIENTAL STUDIES, at 5 30—Prof G Morgensterne The Káirs of the Hindu Kush (1) (Succeeding Lectures on May 4 and 6)  
 ROYAL SOCIETY OF ARTS, at 8—Prof J C Drummond Recent Researches on the Nature and Function of Vitamins (Cantor Lectures) (3)  
 SOCIETY OF CHEMICAL INDUSTRY (London Section) (Annual Meeting) (at Chemical Society), at 8, followed by a General Discussion on Smoke Abatement in Industry

#### TUESDAY, MAY 3

ROYAL ANTHROPOLOGICAL INSTITUTE (African Research Committee), at 4 30—Methods of Study of Culture Distribution in Africa  
 ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr Harriette Chick The Relation of Light to Nutrition (Oliver-Sharpey Lectures) (1)  
 ROYAL SOCIETY OF MEDICINE (Orthopaedics Section), at 5 30—Annual General Meeting  
 UNIVERSITY COLLEGE, LONDON, at 5 30—Dr W A Shewhart The Role of Statistical Method in Industrial Standardisation (1) (Succeeding Lectures on May 5 and 6)  
 GOLDSMITHS' COLLEGE (New Cross), at 5 45—Exhibition in connexion with the Teaching of Geography—At 5 45—Sir Halford Mackinder Inaugural Address

#### WEDNESDAY, MAY 4

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, at 5 30—Aldous Huxley Huxley as a Literary Man (Huxley Memorial Lecture)  
 NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (at London School of Economics), at 5 30—Dr C S Myers Psychological and Social Factors in Business Rationalisation (1) The Significance of Rationalisation  
 GOLDSMITHS' COLLEGE (New Cross), at 5 45—L Brooks The Teaching of Geography—The Modern Approach  
 EUGENICS SOCIETY (at Royal Society)—Annual General Meeting

#### THURSDAY, MAY 5

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers), at 10 A M—Annual Meeting  
 ROYAL SOCIETY, at 4—Election of Fellows  
 ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr Harriette Chick The Relation of Light to Nutrition (Oliver-Sharpey Lectures) (2)  
 LONDON SCHOOL OF ECONOMICS, at 5—Dr R R Marett Covenant in Primitive Economics, Law, and Religion (1) (Succeeding Lecture on May 12)  
 GOLDSMITHS' COLLEGE (New Cross), at 5 45—Prof. E G R Taylor First Ventures on the Atlantic—A Study in the Relations of Human and Physical Geography  
 INSTITUTION OF ELECTRICAL ENGINEERS (Varley Centenary Meeting), at 6—Lt-Col A G Lee The Lives and Work of Cromwell Fleetwood Varley (April 6, 1828) and Samuel Alfred Varley (March 22, 1832)—Annual General Meeting, at 6 45  
 SIR JOHN CASS TECHNICAL INSTITUTE (31 Jewry Street, E C), at 7—Prof C O Bannister Ancient and Modern Metallurgy (Armourers and Biasiers' Company Lectures) (1) (Succeeding Lectures on May 12 and 19)

#### FRIDAY, MAY 6

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers), at 10 A M—Annual Meeting  
 ROYAL SOCIETY OF MEDICINE (Otolaryngology Section) (Annual

General Meeting), at 10 30 A M—Discussion on Labyrinthitis

CAMBRIDGE UNIVERSITY (in Senate House), at noon—Prof A Einstein Die Theorie der Elektrizität im Rahmen der allgemeinen Relativitätstheorie (Rouse Ball Lecture)

INSTITUTION OF MECHANICAL ENGINEERS (London Spring Meeting), at 2 30—A Binns Recent Developments in the Mechanical Equipment of the Port of London Authority

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30—Miss B M le P Power Indian Labour Conditions

SOCIETY OF CHEMICAL INDUSTRY AND INSTITUTE OF CHEMISTRY (Joint Scottish Meeting) (at University, St Andrews), at 5—Prof J Read Alchemical Literature and Iconography (Lecture)

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5—Annual General Meeting

PHYSICAL SOCIETY (in Physiological Laboratory, University College), at 5—Prof A V Hill The Measurement and Analysis of the Heat Production of Nerve (Lecture)

UNIVERSITY COLLEGE, at 5 30—Sir Bernard Pares Russia and the West (Lecture)

GOLDSMITHS' COLLEGE (New Cross), at 5 45—Prof J F Unstead Recent Developments of the Regional Method—as applied to Teaching

ROYAL INSTITUTION OF GREAT BRITAIN, at 8 30—Conversazione

ROYAL SOCIETY OF MEDICINE (Anaesthetics Section), at 8 30—Annual General Meeting

CAMBRIDGE UNIVERSITY (in Anatomy Lecture Room, New Museum)—Prof J J R Macleod Lincro Lecture

#### SATURDAY, MAY 7

GOLDSMITHS' COLLEGE (New Cross), at 3 30—Prof H J Fleure Social and National Ideals in their Geographical Settings—A Study of Some European Problems

## Scientific Worthies

XLVI—THE RIGHT HON LORD RUTHERFORD OF NELSON, O M, F R S

IT is often a matter of surprise to note the profound differences between the methods the human mind adopts towards the problems it is seeking to solve, and any narrow classification would necessarily be inexact because of the variety of possible temperaments. Among the scientific investigators who have devoted their lives to the study of physics, two main tendencies can, however, be noted. On one hand, there are those who are dominated by the abstract aspect. They are interested not so much in the facts as in the theories to which these facts lead. There is no lack of illustrious men to whom the intellectual aspect has appeared the more important, and quite recently striking successes have resulted from just such methods of investigation. Other scientific men, while not denying that the object of science is to correlate and to predict phenomena, and without confining themselves merely to the compilation of facts, yet feel that we are so far from being able to form a logical and clear idea of reality that we are scarcely beyond the point of realising the danger of too abstract generalisations. Such generalisations run the risk of describing more the mind of the man who puts them forward than Nature itself—which is the object of research and of experimental physics. As has often been remarked, facts serve to produce theories, leading in their turn to the discovery of new facts, which may in their turn destroy the theories by which they were discovered.

The scientific career of Lord Rutherford is a splendid example of this second method of physical investigation, and it will be sufficient to show that this point of view is not in any way inferior either in importance or in fertility to the other.

Lord Rutherford's earliest work was in a sphere quite apart from that to which he has since devoted his life, but it showed clearly enough his remarkable qualities as a physicist. He investigated the change in the magnetisation of a steel wire due to the passage of oscillatory currents, and he was able to show that Hertzian waves could, by producing oscillatory currents, cause a sudden diminution in the magnetisation of such a wire. This discovery was utilised later by other workers and developed to form a detector for wireless telegraphy.

The three years, 1895–98, which Lord Rutherford passed at Cambridge working under Sir J. J. Thomson determined the orientation of his future

interests by permitting him to study the newly discovered properties of ionised gases and the causes of this ionisation. He went to McGill University in Montreal imbued with the ideas and inspiration which had enabled Sir J. J. Thomson to make the Cavendish Laboratory a birthplace of famous physicists. It was not long before the young professor found in radioactivity the subject for which his peculiar genius was most suited. It was then 1898, two years after the discovery by Becquerel of the radioactivity of uranium, Pierre Curie and Mme. Curie had just added greatly to the range of the new phenomenon by discovering polonium and radium, and the list of the radioactive bodies already included thorium and the two alkali metals.

While, however, the far-reaching importance of these new discoveries was obvious to everyone, the interpretation of the facts in this new domain presented fundamental problems which remained unanswered. A most important research from this point of view was published in 1900 by Rutherford, from Montreal, when he was able to show that the thorium bodies gave out a type of radioactive emanation. He maintained the view that this was in effect a material gas constituting a new chemical species which should find a place in the family of inactive gases to which helium and argon belonged, and this was ultimately, in collaboration with Soddy, shown to be true. This bold hypothesis received a most striking confirmation when the more marked and more permanent phenomena shown by radium emanation were discovered in their turn.

Following up his researches on thorium, Rutherford was able to detect the presence of an induced radioactivity which he attributed to an active deposit, invisible and yet material, carried in the form of electric particles which could be concentrated on an electrode by means of an electrostatic field. This active deposit was an attribute of the emanation and was thus an example of the affinity which exists between the radioactive bodies. Later, while studying the radium emanation discovered by Dorn, Rutherford found many properties which emphasised its material properties, as, for example, that it could be condensed in suitably cooled tubes. He was also able to obtain a complete spectrum of this new chemical element, which Ramsay and Soddy had shown beyond doubt was a gas. It is very remarkable that Rutherford and Soddy suggested in 1902 that helium might be one of the products of disintegration of the radioactive bodies.

The year 1903 was one of the most decisive for the new science which was then growing up, for it saw in effect the discovery of the production of helium from radium emanation, the fundamental discovery by Curie and Laborde that preparations of radium gave out a continual supply of heat, and it also saw the birth of the theory of radioactive transformations put forward by Rutherford and Soddy to explain the facts shown by the thorium family. At first sight many of the phenomena shown by the radioactive bodies were very strange; the activity did not always seem to depend upon the bodies which constituted the source, it could be carried to a certain distance and could there produce the phenomenon called induced activity, all of which was very obscure. Neighbouring surfaces, without apparently suffering any modification, acquired a power of emitting radiations for which the rate of decrease with time appeared to be connected in a mysterious way with the growth of activity of the primary substance. To-day, when we have a theory of the atom, admittedly rough, but which yet explains in an admirable way a great number of diverse facts, the interpretation of these phenomena, so inexplicable in the early days, now seems simple enough. But if one looks back to the year 1900, when the ideas of the nuclear atom, and of Bohr orbits, were as yet unformulated, it will readily be appreciated what imagination and what sureness of intuition were necessary in order to disentangle so rapidly such a complication of strange and new facts.

Rutherford and Soddy put forward in 1903 a complete theory of these phenomena which permitted the prediction, both qualitatively and quantitatively, of the whole complicated consequence of events. This theory was based on a conception of the utmost simplicity which has since served, without any modification, to classify all the facts discovered in this new domain.

The fundamental idea of this theory is that among the great number of atoms of a body which possess the property of radioactivity, there is a definite probability that in a given time a certain number of these atoms will have changed into a new type by the ejection of a material particle owing to a type of instability. In other words, the number of atoms which change in unit time is always proportional to the total quantity of matter which is then present.

A detailed calculation then showed that such a substance will disappear according to an exponential law, if the new atoms are also unstable and are transformed much more rapidly than the first kind.

(which is the case for uranium, radium, and thorium), there will result a type of equilibrium between the successive descendants of the same radioactive family, so that their relative proportions are perfectly defined in the minerals and in the preparations which contain them. The radiations which are emitted are a direct result of the transformations of the atoms and therefore provide an exact measure of its rate of disintegration.

Schweidler and later Kohlrausch showed that Rutherford's theory, which was at first presented as a kind of analogy with irreversible monomolecular reactions, could be viewed entirely from the point of view of chance and was therefore subject to the laws of the calculus of probability. This was perhaps one of the first examples of the intervention of statistical laws in fundamental atomic phenomena, an idea of which the more recent discoveries of physics have shown both the generality and the profound philosophic importance. In the light of present knowledge, one may well ask to-day whether such a law was not imposed *a priori* to the exclusion of all others.

The laws of radioactive disintegration thus stated formed a framework for the classification of all the new substances produced by the successive transformations of each family. Thus a new chapter in physics and in chemistry was begun, that of matter in a state of evolution, which has led in time to all that we know to-day about radioactivity.

But besides this, the study of the radiations, the investigation of their nature, of their properties, and of their effects, form a peculiarly interesting branch of this new science, and it is only necessary to compare the early works of Mme. Curie and of Rutherford with the latest volumes published by Kohlrausch and by Rutherford to understand the double aspect of the facts grouped under the name of radioactivity.

After 1905, Lord Rutherford directed his efforts mainly to the study of the radiations, and the success which he achieved in this field was not less than that which had greeted his earlier efforts. There are three kinds of rays,  $\alpha$ ,  $\beta$ , and  $\gamma$ , and Lord Rutherford's earliest work was concerned with distinguishing between them. Afterwards, commencing with the  $\alpha$ -particles, he has contributed more than anyone else to establishing the fact that they consist of helium atoms carrying a double positive charge and projected with a velocity corresponding to an energy of several millions of volts. It has been possible not only to study the properties of a beam of  $\alpha$ -rays, but also to detect the effect of single particles and to count them by

direct methods, which in course of time have been developed to a high degree of perfection. The detection of single particles has now rendered possible the detailed verification of the predictions of the law of probability about the distribution of the particles both in space and in time.

The expulsion of helium nuclei and of  $\beta$ -particles, that is, high speed electrons, from the radioactive nucleus, threw a new light on the whole problem of the constitution of atoms. This question had previously seemed so remote that no one had dared thus to think of it before the first ten years of the twentieth century. In fact, it remained so obscure that, at the first Solvay Conference, when it was asked what picture one could form of the emission of spectral rays, the eminent specialists there present were caused merely to reveal their own ignorance on the subject. No one was better placed than Lord Rutherford to make a decisive attack on this problem, by bringing to it a definite atomic model founded on experimental facts.

Various experiments carried out under his direction on the scattering of rapid particles in their passage through matter led to the formulation of an approximate law describing the deviations, and this Lord Rutherford saw could only arise if there was some kind of condensed nucleus forming the central part of the atom. This theory, put forward in 1911, was greatly expanded and developed in 1914, after the splendid theoretical work of Bohr and the notable experiments of Moseley, which were both carried out in Lord Rutherford's laboratory. From this resulted the atomic model universally accepted to-day and known under the name of the Rutherford-Bohr atom. In this model, as is so well known, the atom is supposed to be formed by a central nucleus carrying a positive charge and surrounded by a cloud of satellite electrons, the number of which is equal to the number of the net positive charges on the nucleus. This whole number, called the atomic number, plays an essential rôle in the theory of spectra, in the classification of elements, and in all problems connected with atomic physics. It shows the position of an element in the natural order of the elements, characterises the chemical type, and, in conjunction with the number of protons in the nucleus, constitutes even to-day the data of which we are most sure in relation to the ultimate particles of matter.

The  $\beta$ -rays and the  $\gamma$ -rays also occupied the attention of Lord Rutherford and his school, and in 1914 he was able to obtain for the first time a spectrum of the  $\gamma$ -rays by diffraction from a crystal of rock

salt The experimental method was extremely ingenious and was specially adapted to work with the necessarily small angles of reflection In this way he was able to show that the  $\gamma$ -rays were analogous to the X-rays, but of shorter wave-length

The electrons of different speeds which constitute the  $\beta$ -radiation can be separated out by a magnetic field, and a detailed analysis of this emission, and also the study of the high speed secondary electrons which are produced, formed an important chapter in the researches undertaken at about this time The  $\gamma$ -rays emitted by radioactive bodies form a line spectrum, and while the greater portion of the  $\beta$ -rays form a type of continuous spectrum the origin of which is yet obscure, there is also a series of groups of electrons of definite speed which, when analysed by a magnetic field, form a type of corpuscular spectrum The question as to whether there should be a connexion between these two spectra by means of the photo-electric effect was considered by Lord Rutherford, and later, in the hands of his co-workers, experiments on this subject threw great light on the complexity of the emission of the  $\beta$ -rays In this way it was possible to study the spectrum of the  $\gamma$ -rays, although their wave-lengths were so short as to render the normal method of crystalline diffraction inapplicable

Finally, there is a third phase of Lord Rutherford's work, marked by discoveries no less important than those preceding, and concerned with the artificial disintegration of the lighter elements by bombardment with the  $\alpha$ -particles emitted by radioactive bodies According to present ideas, which are in great part due to the researches which have just been referred to, the chemical properties of an element depend entirely on the value of the nuclear charge Some of the electrons which surround the nucleus can be removed, or even the nucleus may be stripped bare, when the atom would in the first case be partly, and in the latter case completely, ionised, yet still, from the point of view of the chemical nature of the element, it would be the same as at the commencement of the process, and the atom would regain all its former properties as soon as it had recaptured its full number of electrons In order to effect a change in the atomic species, it is essential to change the positive nucleus It may be said, indeed, that the nucleus determines the structure of that portion of space which constitutes the atom This central fort is guarded by strong defences There is an intense electric field which opposes the progress of a projectile which approaches it, and will in fact

prevent its arrival unless it be endowed with very great energy It occurred to Lord Rutherford that the  $\alpha$ -particles did in fact constitute precisely the most powerful type of projectile at our disposal for attacking the nucleus, and he proceeded to use this weapon

It was therefore in 1919 that for the first time an actual case of chemical transmutation of an element was proved scientifically It was found that the hydrogen nuclei, which are to-day called protons, could be detached from the nuclei of nitrogen and other bodies by bombardment with  $\alpha$ -particles In the case of aluminium, the explosion sets free a certain quantity of intra-atomic energy, which gives the proton greater energy than that of the incident projectile

This was the beginning of a new branch of physics and chemistry, that of artificial radio-activity At first progress was somewhat slow, due to inherent difficulties in the early experimental methods, but now the science is making great strides There is little doubt that it will quickly lead to important results and throw light on the intimate details of this new world of nuclei which the work of Lord Rutherford has opened up for the physicists of the future

As professor of physics at Manchester—where he obtained in a few years so many striking results that it has been possible to form a museum of historic apparatus—and then at Cambridge, a successor to the great line of illustrious physicists of which the last, Sir J J Thomson, had just retired after influencing the whole subject of physics in a way which becomes more apparent every day, Lord Rutherford has continuously affected all those who surround him by his personal influence He has maintained and even increased the great traditions of the Cavendish Laboratory, from which have come so many admirable researches and so many notable men of science The list of the physicists who have worked under his direction is a long sequence of names of which the greater number have attained fame, and in no small measure is the brilliance and certainty of the results due to the continual co-ordination of a series of researches directed towards one end The number of distinguished physicists who have co-operated in this advance is so large that it would be impossible to mention all and invidious to choose a few, but reference to any work on radio-activity will show how many have worked under Lord Rutherford and collaborated in his researches.

Taking Lord Rutherford's work as a whole, one finds that underlying it there is always a concrete

picture of the problems based on direct experiments, and then, avoiding all mathematical complications, these experimental facts are connected up by means of a theory which gives a direct visual picture of the phenomena. Recent theoretical views suggest that such a mechanistic view of Nature cannot be pushed beyond a certain point, and that the fundamental laws can only be expressed in abstract terms, defying all attempt at an intelligible description. The philosophy of science has always swung between these two points of view. The work of the great physicist to whom these lines are dedicated shows, however, to what brilliant discoveries the method followed by Lord Rutherford can lead.

M DE BROGLIE

### New Guinea Sorcerers

*Sorcerers of Dobu the Social Anthropology of the Dobu Islanders of the Western Pacific* By Dr R F Fortune Pp xxviii+318+8 plates (London George Routledge and Sons, Ltd, 1932) 15s net

DR FORTUNE has given us a remarkably interesting and valuable account of the natives of the islands of Tewara, Dobu, and of the village of Basema, all in the D'Entrecasteaux group, which lies off the south-east end of New Guinea. Previously we had only the general observations of government officials in the Annual Reports of Papua, the useful little book "The Northern D'Entrecasteaux", by Jenness and Ballantyne (Oxford, 1920), and a few notes by various travellers. The great merit of this book is that it describes the functioning of society and of social activities—it is thus a dynamic survey and not merely an account of social structure, as has usually been the case in previous ethnological studies—and, indeed, it is a good illustration of the modern method of field-work.

The social unit of the Dobuans is the *susu*, or matrilineal group, of which a variable number constitute a village. Every husband must come from another village, and he has but a precarious position in his wife's village, as there is a strong solidarity between the wife, her brothers, and all other members of that *susu*, and, in addition, divorces are frequent. Every alternate year the family lives in the wife's and in the husband's village. When a man dies, he is buried in the domicile of his own *susu*, and thereafter his children may never enter that village. The marital group, or simple family, is necessarily weak as compared with the *susu*, and each village contains a hetero-

geneous collection of men from different villages, who distrust one another. A man cannot alienate from his sister's children, in favour of his own, his village land, his personal name, his skull, his status, or his fruit trees, but he can, and often does, teach his son his magical formulæ, and he is obliged to teach these to his sister's son. Teaching both parties is really a subversive action, as magic gives power, status, and a small income, and when put in the hands of individuals who are very apt to be antagonistic they may use it one against the other. A father will never give his magic to more than one son, the others are left magicless, with the result that blood brothers are usually very jealous of one another. Practically all property descends in the *susu*, but a father may give some garden land that lies away from the village to his son, as well as to his sister's son, but no child can eat of any fruit or crop grown on land that was his or her father's, though such food can be exchanged for food from someone else's dead father's land.

All activities such as gardening, the lashing of canoes, the love between man and woman, and even disease, death, wind, and rain, are supernaturally created by the ritual of incantation with the help of the appropriate technological processes, gifts, and the like. Technology and mundane measures are not to be despised, but the incantation is the really important factor. Incantations are directed to supernatural beings, many of whom originally were human beings but are now immortal, their names are never pronounced except in inaudible undertone in actual ritual. It was they who originated the formulæ and gave them to the first ancestors of man, but nothing happens if the possessor of the formulæ does not use it. For example, in the ritual addressed to seed yams, the man is not muttering a form of words to yams merely, he is addressing a Personal Being, for yams are such in a metamorphosed form. The section on social organisation in gardening and the ritual of the garden are of particular interest.

Sorcery permeates the whole life of the Dobuans and is an integral part of their supernatural system; it "is practised by everyone, and believed in firmly by everyone. Like most supernatural systems it enlists its believers, not by tricks, deceits, and stratagems, but by a more dignified faith in the reality of Unseen Forces, and in the reality of the power of human speech to affect these Unseen Forces, that were 'born with the sun and the moon and the earth'." In an appendix, Dr Fortune criticises the action of the administration towards sorcery.

The system of periodical ceremonial exchanges of valuables between a circle of islands, known as *kula*, which was first described in a masterly manner by Malinowski, is here dealt with from a somewhat different angle. One group of a particular kind of valuables passes in one direction and another kind in the opposite direction, but the retention of them is purely temporary and they circulate indefinitely. Dr. Fortune makes the illuminating remark that the *kula* is like an annually repeated peacemaking ceremony, hence "the *kula* exchange of ornamental valuables, useless enough in itself, helps to maintain annual exchanges of other" and useful objects. The peoples of the islands are great traders, as has been shown by Seligman, but we are told that it is all done without direct barter. There is no haggling, it is a matter of giving and receiving presents. The great prestige of the *kula* undoubtedly makes strongly for peaceful relations between potentially hostile internationalists, and at the same time is a strong protection to ordinary trade in an area rent by the fear of the black art, suspicion, and hostility.

In his introduction, Prof. Malinowski makes some comparisons between the Dobuans and the Trobrianders, and the present writer agrees with him in his appreciation of the importance of Dr. Fortune's investigations and the manner in which he has presented them.

A. C. HADDON

### The Assembly of the Sages

*Turba Philosophorum ein Beitrag zur Geschichte der Alchemie* Von Julius Ruska (*Quellen und Studien zur Geschichte der Naturwissenschaften und der Medizin. Fortsetzung des Archivs für Geschichte der Mathematik, der Naturwissenschaften und der Technik. Herausgegeben vom Institut für Geschichte der Medizin und der Naturwissenschaften.* Redigiert von P. Diepgen und J. Ruska, Band 1.) Pp. x+368 (Berlin: Julius Springer, 1931.) 58 gold marks.

ANY man of science who wishes to see scientific method applied to solve literary and historical problems will savour intense intellectual delight in Prof. Ruska's book on the "Turba Philosophorum". A major enigma in itself, the *Turba* comprises a multitude of lesser riddles, and though the author with characteristic modesty describes his work as a mere preliminary study, he will be found to have left but comparatively little for future research to unravel. Like the Emerald Table of Hermes, upon which also Ruska has published a valuable investigation, the *Turba* enjoyed an authoritative reputation among

medieval alchemists, and was confidently quoted whenever it was desired to clinch an argument or conclusively to refute an opponent. An English version of this alchemical classic was made so long ago as 1896, by the learned historian of occultism, Mr. A. E. Waite, but a critical study of the problem as a whole remained unattempted until Prof. Ruska began his systematic work upon it in 1927.

Briefly put, the problem is as follows. In the form of *dicta* and of question and answer, the *Turba* purports to convey the alchemical tenets of an assembly of sages, some of whom have Greek names, while the names of others appear to have no parallel in any known tongue. Though the early manuscripts are in Latin, the queer phraseology and reprehensible syntax indicate that Latin was not the original language of the work, while numerous Arabic constructions and idioms, together with a large admixture of Greek alchemical ideas, seem to suggest that the *Turba* was written in Greek, translated into Arabic, and thence rendered into Latin. The principal part of the problem is thus to settle the origin of the treatise, the lesser, but by no means insignificant part, is to interpret the bizarre names and words that it contains, and to discover its affiliation to other early alchemical writings. Prof. Ruska's conclusion upon the chief point will be found irrefutable, his ingenuity in grappling with the others must excite our admiration as his faultless logic compels our assent.

The first fact that emerges from a close examination of the *Turba* is that the extraordinary proper names are to be regarded as Latin attempts to transcribe Arabic versions of Greek names. Proceeding from this basis, Prof. Ruska considers (a) the Arabic system of transcribing Greek words, and (b) the Latin system of transcribing Arabic words. Application of this method to the names in the *Turba* has led him to make a large number of unexpected but quite convincing identifications. Thus Iximidrus proves to be Anaximandros, Pandolfus is none other than Empedokles, Lucas is not Lucas but Leukippos, and Bonellus is the curious corruption of Apollonius as Horfolcos is of Herakleios. We may follow the steps of one of these remarkable equations. In medieval Arabic, Empedokles is rendered ANBADAQLIS. By the mere omission of an *alif* and a slight displacement of diacritical points this becomes BANDAFILUS, whence the Latin transcriptions Pandolfus and Pandophilus are seen to be not merely intelligible but almost inevitable.

The abundance of Greek personal names in the

Turba might seem to lend support to the thesis of a Greek origin of the work, but other facts definitely negative it. In the first place, it cannot be doubted that the Latin version is a direct translation from the Arabic, for in addition to the evidence just described, Prof. Ruska shows that many phrases and sentences are literal renderings of common Arabic formulæ. Most striking, perhaps, is the occurrence in one passage of a sentence from Sura 112 of the Koran. *Dico tamen, quod Deus unus est, nunquam genuit nec genitus est*. In a manuscript of the Turba at Erfurt, the copyist has added "secundum Sarracenos" to this heretical statement, while in other examples the offending words have been altered to *unumque genuit neque tamen genitus est*.

Yet the fact that the Latin Turba is a translation from the Arabic does not, in itself, exclude the possibility that the Arabic Turba may also have been a translation—a translation from the Greek. It would be easier to settle this question if Arabic manuscripts of the work were available, but although one at least was in existence in Cairo in 1537, none is known to be extant at the present day. Excerpts from the Turba are, however, to be found in certain other Muslim alchemical treatises, and it is not too much to hope that the whole book may be discovered sooner or later in some Cairene or Indian library. In spite of the lack of a complete Arabic text, Prof. Ruska is able to show—conclusively, as we think—that the Turba is not a translation from the Greek, but the original composition of some unknown Islamic chemist, probably of the ninth or tenth century. To summarise his arguments within the present limits is impracticable, but the attentive reader—especially if he be familiar with Muslim alchemy—will find that they carry conviction.

Prof. Ruska has completed his investigation into the sources of the Turba by the establishment of a critical Latin text, and by a careful and fully annotated translation into German. The fourth and concluding part of his book is a consideration of the literary problems involved, in which such points as the theological, cosmographical, and alchemical ideas of the Turba are discussed and elucidated. There are excellent indexes, and the typography is of a very high standard. Every scholar for whom the history of science holds interest will congratulate Prof. Ruska upon his brilliant achievement, and will congratulate himself upon the opportunity to add to his shelves a work as full of fascination as of sound learning.

E. J. HOLMYARD

## Rock Structures and their Interpretation

*Principles of Structural Geology* By Prof. C. M. Nevin. Pp. xi+303. (New York: John Wiley and Sons, Inc., London: Chapman and Hall, Ltd., 1931.) 17s. 6d. net.

THIS admirable book is one of the most competent and stimulating of the contributions to geological literature that have appeared in recent years. Structural geology is defined as the study of the framework of the earth's crust—and in its broader phases of the entire earth—and the causes responsible for its deformations.

After a preliminary chapter on the physical properties of rocks, the principles of the subject are developed, with special attention to the conception and application of the strain ellipsoid. Thus from the outset, ability to reason in three dimensions is made possible to the careful student. The author is, indeed, to be gratefully congratulated on the ingenious use he makes of this powerful instrument for structural analysis. Special care is taken to show that more than one interpretation may be possible of the evidence seen in the field, and "matters now in dispute among geologists are not avoided simply because they are unsettled." Successive chapters deal carefully and lucidly with flexures, faults, joints, cleavage, and structures in unconsolidated sediments. The illustrations and diagrams are excellent throughout. Each chapter affords the author an opportunity of discussing some of the larger problems of geology, with the result that the book is not only an unsurpassed guide to students but also a storehouse of valuable hints and clues which merit consideration by structural geologists in general.

The remaining chapters are devoted to rock structures and topography, and to more speculative matters regarding the earth as a whole, and such questions as isostasy, continental drift, and mountain building. Here, as throughout the book, Prof. Nevin follows so far as practicable the spirit of Voltaire: "Let us make an exact analysis of the matter and then we shall try to see, with much diffidence, if it fits any principle." The general working hypothesis is advanced, though in no dogmatic manner, that the earth is continually being deformed, that "separated periods of quiet and intense stress are true for localised areas such as the seats of future mountain ranges, and even for continental masses, but are mythical when applied to the earth as a whole." It is concluded that the contraction hypothesis rests on a very insecure foundation, that the possibility of

continental drift can no longer be safely ignored, and that the forces which cause mountain deformation and major vertical uplifts still remain complete mysteries

The book is so good that it presents an adequate excuse for asking for more. In a future edition, which should be called for at no distant date, chapters might well be added on igneous bodies and on rock-flowage. The index is not so full as it might be. Very few misprints or errors of fact have been noticed. On page 6 the term *amorphous* is used as if it did not include certain materials having strength. On page 229 *uranium* is twice printed where *radium* is intended, and determinations of radioactive elements in rocks are wrongly attributed to Kolhorster. Elsewhere the name of Jeffreys is given without the final letter. These slips, however, are negligible compared with the indisputable fact that Prof. Nevin has enriched geological literature with a treatise that is at once a textbook of outstanding importance and a discussion of earth problems that no geologist can afford to overlook.

### Short Reviews

*Vorlesungen über theoretische Physik an der Universität Leiden*. Von Prof. Dr. H. A. Lorentz. Band 5. *Die Maxwell'sche Theorie (1900-1902)*. Bearbeitet von Dr. K. Bremekamp. Übersetzt von Dr. H. Stuecklen. Pp. vii + 199. (Leipzig: Akademische Verlagsgesellschaft m. b. H., 1931.) 16/20 gold marks.

THE influence of the teacher, as exhibited in his lectures, may be powerful and lasting, but if his lectures remain unpublished, that influence is confined to the comparatively narrow circle of his direct hearers, and it becomes as difficult for one who has not sat at the feet of the teacher to appreciate his gifts as it is to judge at second hand the art of Garrick or of Kemble. Happily, the pious care of the pupils of Prof. Lorentz has rescued from oblivion much of value in his routine teaching, and we are fortunate not only in the worth of the subject matter thus permanently placed on record, but also in the picture it provides of another aspect of a great personality, a great advancer of knowledge, who is now seen as an inspiring teacher.

Whatever Lorentz touched, however commonplace or well worn the theme, he made his own. The lectures earlier printed showed us his clarity of thought, his systematic manner of building up his subject, and his rare capacity for wide and philosophic generalisation combined with attention to minute detail.

These qualities are again apparent in this compact volume, which opens with a section containing a brief but luminous discussion of the elements of vector algebra, of Stokes's and Green's theorems, of the

equations of Laplace and of Poisson. Maxwell's equations are then developed, and chapters follow which deal with electrostatics, steady and induced currents, the energy in the electromagnetic field, and the electromagnetic theory of light. It would be difficult to find a clearer development of the subject confined within the moderate compass of less than two hundred pages.

ALLAN FERGUSON

*Minds in Arrear: some Practical Aspects of Mental Deficiency*. By Dr. E. B. Sherlock. Pp. ix + 181. (London: Baillière, Tindall and Cox, 1932.) 5s.

DR. SHERLOCK was, until recently, medical superintendent of the Darenth Training Colony in Kent, so is particularly fitted to deal in an authoritative manner with any questions of mental defect. He wisely points out that his small book, "Minds in Arrear", is meant primarily for the general reader and not for the specialist. His attitude towards the generic term for mental defect is very broad-minded and in keeping with the most recent opinion. There is a growing tendency to get rid of, if possible, the term *amentia*, which means 'absence of mind' and is also used in Norway, Holland, and Italy to connote what is understood as confusional insanity. The word *oligophrenia*, invented by Bleuler, is a clumsy word, but will probably be finally adopted for international use.

Dr. Sherlock contrasts the normal mind with the abnormal mind, differentiating inadequacy of stimulus from inadequacy of response. The inadequacy of response is made up of paucity of ideas, defective apprehension, an inability to concentrate, poorly developed general intelligence, and abnormal affects.

The remarks on sterilisation are very guarded, and we only wish that other writers on this vexed subject would weigh their evidence as carefully as he does. It is wisely pointed out that sterilisation, to have any value, would have to be compulsory. The majority of defectives are not the offspring of people themselves defective, so that compulsion would be a difficult matter. Segregation, although it may be an expensive matter, is of considerably greater value as a matter of practical politics.

The author's plea that mental defectives should be brought within the provisions of the Mental Treatment Act, 1930, has a great deal to commend it, and is a move in the right direction.

*Difficulties of the Evolution Theory*. By Douglas Dewar. Pp. viii + 192. (London: Edward Arnold and Co., 1931.) 12s. 6d. net.

A LABORIOUS anthology of facts which have not been completely elucidated by evolutionists, leading up to the conclusion that new forms of life arise by creation and may be afterwards modified, in minor respects, by gradual evolution. The following is a novel contribution to the anti-evolutionist case. "Another feature not easily reconciled with the evolutionary theory is the great disparity in the span of life of various animals. If every organism be descended from a common

ancestor, would such enormous differences exist? Why should a parrot live to over 100 years while the pheasant apparently does not live longer than 15 years, why should an elephant live for as much as 120 years, while no rhinoceros is known to have lived more than 37, and no hippopotamus more than 33 years, why should the cat live three times as long as the guinea-pig? As the vast majority of individuals in a state of nature are killed long before they have reached their full span of life, and as species the members of which are long-lived do not seem to be more flourishing than those of which the members are short-lived, it does not seem possible that the disparity in longevity has arisen as a result of natural selection. If, however, the various types have been created independently, we should expect this disparity in the span of life, because the *raison d'être* of these types is the stocking of the earth with a great variety of forms, and length of life is a characteristic that offers ample scope for variety. In an appendix, the author discusses at length "The alleged origin of mammals from reptiles", without once mentioning the ear-ossicles.

G. P. W.

*Industrial Microbiology the Utilization of Bacteria, Yeasts and Molds in Industrial Processes* By Prof H. F. Smyth and Prof W. L. Obold. Pp. x + 313 + 3 plates. London (Baillière, Tindall and Cox, 1930) 27s net.

THIS book is devoted to an account of the ways by which industry has utilised the chemical activities of bacteria, yeasts, and moulds. It is divided into twelve sections, beginning with accounts of the production of carbocyclic acids, alcohols, and ketones, and followed by a discussion of the way in which carbohydrates, such as cotton, hemp, jute, cellulose, etc. are by microbiological activities dealt with in industry. Further sections on the production of foods and other commercial products complete the volume. The general purpose of the book is to bring before manufacturers, and students thinking of entering this field of work, the information already available but scattered through a wide field of scientific journals and technical publications. On the whole, the authors have done their work fairly well, though their spelling and structure of sentences leave much to be desired. Their decision to make the bibliography a selected one and not complete is wise, since the uninitiated student with a long list of references before him is apt to waste a good deal of time reading unnecessary papers before reaching the ones that are of real importance to his subject.

- (1) *The Children we Teach Seven to Eleven Years* By Dr Susan Isaacs. Pp. 176 (London University of London Press, Ltd., 1932) 3s 6d net.
- (2) *Education of the Backward Child* By David Kennedy-Fraser. Pp. 254 + 4 plates (London University of London Press, Ltd., 1932) 6s net.

THE reason why we mention these two books together is that they both bear upon the problems of education, and the reason why we mention them

at all is that they are both examples of scientific method in the field of educational inquiry. The older philosophic method of approach to psychological questions is well known to have been to a great extent replaced by a scientific method of approach. The same may be said of the serious study of education. This used to be the business of the philosopher and of the psychologist who drew his inspiration from philosophy. Now the serious study of education is also undertaken by modern psychologists like Dr Susan Isaacs and Dr Kennedy-Fraser, both of them well equipped for the respective tasks undertaken in these two books. (1) Dr Isaacs writes simply, but with the simplicity of one who knows the complexities also, about normal children of the junior school age. The subject is a timely one, and for most parents and teachers there is a message on nearly every page of her book. (2) Dr Kennedy-Fraser has made a study of the backward child, who may be backward in a temporary or in a permanent sense, and is not to be confused with the mentally defective child. The backward child, as here defined, has not received the attention that he deserves, whether from administrators or from psychologists. This book helps to fill a gap in our educational literature.

*Handbuch der Pflanzenanatomie* Herausgegeben von Prof. K. Linsbauer. Lieferung 28. Abteilung 2, Teil 2. *Bryophyten*. Band 7/1. *Anatomie der Laubmoose*. Von Wilhelm Lorch. Pp. viii + 358 (Berlin: Gebrüder Borntraeger, 1931) 37 50 gold marks.

THE new volume in Linsbauer's "Handbuch der Pflanzenanatomie" on the anatomy of mosses, by Wilhelm Lorch, gives a useful survey of the literature on the subject, but the striking feature of the volume is the amount of original work contributed by the author. Results of previous workers have been reinvestigated, new facts added, and the majority of the very numerous text figures are original.

The text reveals that development has been followed in considerable detail, from this, points of interest emerge with regard to the behaviour of the adult tissues. For example, it is stated that the rupture of the calyptra from the vaginula takes place in the region of the last division in the intercalary growth of the archegonium, which follows fertilisation of the ovum. The interesting section on peristome development also is suggestive that the order of divisions in the meristem is most important, and one regrets that the figures of the developmental stages do not give a rather clearer picture of the condition of the cells in the various regions at different times.

The section on the chemistry shows that cellulose is the usual basal substance of the walls, though this is often masked by impregnation with tannins or other substances. In relation to the ease with which water is taken up by almost any part of a moss, it is also of interest to find that the presence of an appreciable cuticle has been confirmed for a considerable number of species.

## Structure of Atomic Nuclei

TO give a report of a discussion on a subject so complicated as the physics of the nucleus would be an arduous task at any time, but when it is an occasion for dealing with two new discoveries, it is a task the difficulty of which is sufficient excuse for any shortcomings. Not only did Dr J Chadwick describe his experiments leading to the identification of the neutron at the discussion on the subject at the Royal Society on April 28, but also Lord Rutherford reported that Dr Cockcroft and Dr Walton, working in the Cavendish Laboratory, had succeeded in effecting the artificial disintegration of several elements with protons from a high potential discharge tube.

The discussion was opened by Lord Rutherford in a characteristic address. Referring briefly to a number of different subjects, he showed convincingly how rapidly the subject of nuclear physics has extended in recent years. There is now a variety of lines of attack upon what he has appropriately termed the central problem of physics. Optical methods have been shown to lead to information about the masses of isotopes and the type of statistics they obey, while the details of the hyperfine structure give a direct measurement of the nuclear spin. Radioactivity has shown itself capable of revealing new details about the heaviest nuclei, and a close investigation of the  $\alpha$ -rays has thrown new light on the origin of the  $\gamma$ -rays. Quite apart from the information they yield about the nuclei from which they originate, the  $\gamma$ -rays and  $\alpha$ -rays have proved as useful in recent years as in the past for investigating the fundamental laws governing high frequency radiation and high speed particles. A new type of absorption of electromagnetic radiation by the nucleus has been brought out by the work of Meitner, Hupfeld, Tarrant, and Gray, which the last two workers believe to involve a true excitation of the nucleus.

In the more colloquial sense, however, it is in the field of artificial disintegration that the most exciting results have been obtained. A great deal of work has been carried out in different laboratories recently on the production and control of high voltages, and Cockcroft and Walton, working in the Cavendish Laboratory, have developed the technique of producing and using steady high potentials so high as 600,000 volts. They investigated the effect of bombarding lithium with protons of a few hundred thousand volts, and found the striking result that the lithium nucleus can absorb the proton and break up into two  $\alpha$ -particles, each of which recoils with an energy corresponding to more than eight million volts (NATURE, April 30, p. 649).

The experiments are simple in principle even if the technique is difficult. By means of a specially built discharge tube, protons are accelerated up to energies of several thousand volts. They are allowed to fall on a screen covered with lithium, to the side of which, and just outside the tube, is placed a zinc sulphide screen. A window covered

with thin mica is arranged in the side of the tube, so that particles coming from the lithium can, if they have sufficient energy, reach the zinc sulphide screen. It was known from previous measurement that the protons themselves had not sufficient energy to penetrate the mica and reach the zinc sulphide screen, even if they were reflected from the lithium oxide without loss of energy. Bright scintillations were observed in the zinc sulphide as soon as the energy of the proton beam exceeded 120 thousand volts, and the numbers of these scintillations increased very rapidly as the voltage was raised. The particles causing these scintillations had a range in air of about 8 cm, whereas the protons responsible for their emission could only penetrate about 1 cm. This simple fact alone is a definite proof that disintegration involving a large emission of energy had occurred. The general character of the scintillations, coupled with the range of 8 cm, suggested that these particles were  $\alpha$ -particles, and this was borne out by the nature of the tracks obtained in an expansion apparatus. The process is therefore imagined to be

From Aston's accurate measurements of the masses of these atoms, it follows that there would be a liberation of from 15 to 17 million electron-volts of energy in this process, in excellent agreement with the energy of  $8 \times 10^6$  electron-volts which helium nuclei need in order to have a range of 8 cm. While it therefore seems almost certain that this is a correct description of what is happening, Cockcroft and Walton were careful to emphasise that the nature of the high speed particle liberated in the disintegration had not yet been definitely established. Additional evidence will be provided if it is possible to show, as would follow from this hypothesis, that the particles always occur in pairs travelling in opposite directions.

The magnitude of the effect may be illustrated by the following figures. The effect becomes appreciable once the proton beam is accelerated with more than 120 thousand volts, and at 250 thousand volts one disintegration particle was obtained for about every  $10^9$  protons hitting the lithium. The tube could be run at several microamperes, and since one microampere corresponds to about  $10^{13}$  protons per second, it is clear that even with small solid angles there are plenty of particles to detect. Herein lies one of the important advantages of this new method. The yield of disintegration particles obtained even with the eight million volt particles from radioactive bodies is only of the order of one millionth, and it is a very powerful radioactive source which emits  $2 \times 10^9$   $\alpha$ -particles per second, and those in all directions. It is easily seen that, despite the inefficiency of these low velocity protons, the actual number of disintegrations that can be effected is very much greater than with particles of radioactive origin, due to the large number of protons that can be used.

In still another direction this discovery is of importance, since it gives a different type of nuclear disintegration. Using  $\alpha$ -particles, it has been found that a proton is ejected and the  $\alpha$ -particle is captured, forming an atom of greater mass. If protons cause a disintegration, they must form an atom of smaller mass and lower in the periodic system.

Similar experiments have been tried with other elements, and it has been found that beryllium, boron, carbon, possibly nitrogen, fluorine and aluminium all give particles of characteristic range and of greater energy than the incident protons, oxygen and copper gave no effect. While disintegration occurred with both boron and aluminium with protons of energy so low as 150 thousand volts, with the other elements it was necessary to go to more than 300 thousand volts before noticeable effects were produced. It would therefore seem that the greater majority of the lighter elements can be disintegrated by bombardment with protons. While it is easy to speculate that processes such as

may occur, there is as yet no evidence about the nature of the particles except that which has been described in the case of lithium, and conclusions of any kind are mere guess-work until more information has been obtained.

Dr Chadwick began by describing the results that have been obtained from investigating the collisions of  $\alpha$ -particles with the nuclei of the lighter elements. Scattering experiments on one hand, and artificial disintegration experiments on the other, have combined to yield a wealth of information that could scarcely have been anticipated a few years ago. If these experiments of Chadwick and others are not discussed here, it is not because of any lack of recognition of their fundamental importance and interest, but merely to come more quickly to Chadwick's discovery of the neutron.

Bothe and Becker first noticed that a very penetrating radiation was emitted when beryllium was bombarded with  $\alpha$ -particles. Working with this beryllium 'radiation' and using an ionisation method, Joliot-Curie and Joliot found the surprising result that protons were ejected when it passed through materials containing hydrogen. If, as had always previously been supposed, this beryllium 'radiation' was of electromagnetic nature, the quantum would have to have an energy of  $50 \times 10^6$  volts to account for the observed range, 30-40 cm in air, of the protons. In addition, it was particularly difficult to understand how the absorption process could occur so frequently.

Chadwick investigated this phenomenon, using the powerful valve counter methods which had been developed in the Cavendish Laboratory, and found some most surprising results. It appeared that this beryllium 'radiation' liberated particles from all light elements through which it passed, but if these processes were held to be due to interaction with some electromagnetic radiation, the quantum had to be  $100 \times 10^6$  volts from the results with nitrogen,  $150 \times 10^6$  volts from argon, whereas the value  $50 \times 10^6$  volts was obtained from experiments

with hydrogen. Chadwick realised that these difficulties disappeared if the beryllium 'radiation' were assumed to be of corpuscular nature, and then the particles detected by the valve counter would be atoms of the material radiated set in motion by collision with these corpuscles.

Now the beryllium 'radiation' is extremely penetrating, it loses less than one-half of its intensity in passing through one inch of lead, so that if it is corpuscular, then the corpuscles must be only very slightly affected by the atoms through which they pass. This can only mean that the field of influence of these corpuscles is limited to a minute space around them, and that they can pass close to an electron or nucleus without disturbing it or giving energy to it. A neutron, that is a proton and electron in close combination, would have just such properties, and, moreover, if its mass were about unity, and its velocity sufficiently high, it could set other atoms in motion on the rare occasions of direct collisions with the nuclei.

Important confirmation of the correctness of these general ideas was furnished by experiments in which the beryllium 'radiation' was passed through nitrogen contained in an expansion chamber. While no tracks were found corresponding to the neutron itself, clear photographs were obtained of nitrogen recoil atoms set in motion by the process already described. Chadwick has produced convincing evidence of the accuracy of this hypothesis by the following arguments based on his experiments. From measurements of the ranges, he determined the maximum velocities  $u_{\text{H}}$  and  $u_{\text{N}}$  which hydrogen and nitrogen nuclei could acquire by collision with a neutron. This evidently occurs in a head-on collision, so that if  $m$  and  $v$  denote the mass and velocity of the neutron, it follows from the conservation of energy and momentum that

$$u_{\text{H}} = \frac{2m}{m+1} v \\ u_{\text{N}} = \frac{2m}{m+14} v$$

Inserting the experimental values, he obtained a value for  $m$  slightly greater than unity, and a velocity about  $3 \times 10^9$  cm per second. He obtained a far more accurate estimate of the mass of the neutron from a consideration of its origin. Chadwick and also Joliot-Curie and Joliot had discovered that neutrons are liberated from boron as well as from beryllium. In the former case the process is presumably

where  $n^1$  denotes the neutron of mass about unity. Aston has made accurate measurements of the masses of boron, helium, and nitrogen, so that utilising the connexion between mass and energy given by the relativity theory, the energy balance of the process can be examined. It is found, taking into account the kinetic energy of the  $\alpha$ -particle, that the velocity of the neutron, obtained by the method already mentioned, can only be accounted for if the mass of the neutron lies between 1.005 and 1.007. Since the mass of a free hydrogen atom is 1.0078, it follows that the energy of binding of

hydrogen. The oils are distilled, and the heavier fractions used for pasting the coal. The petrol obtained requires only a slight purification treatment prior to use.

The intermediate oils are passed to a vapour-phase converter, where further hydrogen is added, and the mixture of hydrogen and oil vapours is passed over a catalyst, a petrol is obtained from this vapour-phase hydrogenation product by distillation after reduction of pressure. The residual oil obtained in this phase may be re-cycled, or may be sold as diesel oil. The heavy oil residue from the first converter can be blown out, and the liquid product recovered, the residue from which is a solid

coal consumption is therefore 3.15 tons (reckoned dry and ash-free), or 3.65 tons of actual coal, per ton of petrol produced. The overall thermal efficiency is 43 per cent, as will be seen in Fig. 4.

The figures for cost given by Imperial Chemical Industries, Ltd., now work out at about 7d a gal., of which 2d is the cost of the coal. It will be seen that this petrol cost is actually less than the present duty, so that at the moment, in a plant of sufficient size, petrol from coal could compete very easily with petrol from foreign sources. Some time ago I was given an opportunity of examining both the technical and financial sides of the Billingham plant, and although at that time so low a figure as 7d a gal. had not been reached, it was already evident that 8d or 9d a gal. would not be exceeded.

#### HYDROGENATION OF TAR

The treatment of high and low temperature tar by hydrogenation is another method of producing from home sources a supply of motor spirit. Work on this subject has been carried out by Ormandy and Varga, and at the Fuel Research Station. The Gas Light and Coke Co. is also investigating the method in order to find a more favourable market for certain of its tar fractions which are at present almost a drug on the market. A small

continuous plant for the hydrogenation of tar has been erected at the Fuel Research Station. The low temperature tar obtained by carbonising coal at 700° C. with 10 per cent steam has been treated in this plant, 150 gal. of motor spirit and 65 gal. of diesel oil were obtained per ton of low temperature tar treated, whereas by straight distillation the corresponding figures would be 15 gal. of motor spirit, 117 gal. of heavier oils, and 884 lb. of pitch.

#### MECHANISM OF THE HYDROGENATION REACTION

Much further experimental work will be needed to explain the precise effect of hydrogenation on the various constituents of coal, crude oil, or tar, which are all very complex substances, but we already know that the hydrogenation action is a progressive one. When coal is subjected to hydrogenation, the first action is that it becomes plastic, and if hydrogenation is stopped at this stage a pitch-like material is obtained. If a non-coking coal is mildly hydrogenated, it is converted into a material possessing marked coking properties, and so we have for the first time the possibility of converting non-coking coal into coking coal, which, it must be admitted, is not at present an attractive commercial proposition.

An interesting paper describing investigations into the "Thermal Decomposition of Hydrocarbons", namely, methane, ethane, ethylene, and acetylene, was given by Bone and Coward to the Chemical Society in 1908. The character of the products formed when these gases were heated, either alone or in the presence of hydrogen, was examined, and it was concluded that "in the cases of ethane and ethylene, it may be supposed that the primary effect of high temperature is to cause an elimination of hydrogen with a simultaneous loosen-

FIG. 3.—Diagram showing ingoing and outgoing products in a hydrogenation plant of 1000 tons a day.

material containing ash, together with some 5 per cent of the original coal, it could be used only under the boilers. A diagram showing the ingoing and outgoing products in a plant designed for the hydrogenation of 1000 tons of coal a day is shown in Fig. 3.

By re-cycling, etc., in the plant at the Fuel Research Station, some 140 gal. of motor spirit per ton of coal as charged could be obtained, but this has been appreciably exceeded in the large-scale Billingham plant. In this, 100 tons of coal reckoned on the dry, ash-free basis) is capable of yielding 62 tons of petrol and 28 tons of gas, leaving a residue of about 6 tons of partially converted material. The gas can be used for hydrogen manufacture, and the residue for firing boilers.

For each ton of coal hydrogenated, a further ton is required for raising steam for hydrogen manufacture and power generation, and for making the producer gas required for the process. The overall

gaseous products finding their normal markets, the coke is then subjected to the water-gas process so as to produce a mixture of carbon monoxide and hydrogen. By the use of various catalysts, together with, if necessary, additional hydrogen, liquids of various types are obtainable. Such catalytic conversion has been investigated in Germany by Fischer and the Badische Anilin und Soda Fabrik, in France by Patart and his co-workers, and in England by Prof G T Morgan at the Chemical Research Laboratory, by Prof W A Bone at the Imperial College of Science and Technology, and by Imperial Chemical Industries, Ltd. Dr Franz Fischer, of Mulheim, working at atmospheric pressures, has produced liquid and solid hydrocarbons of the petroleum series. Oxygen-containing products are absent, and a yield of 100 gm of solid, liquid, and liquefiable hydrocarbons is claimed from each cubic metre of water-gas.

#### CONCLUSION

On the technical side much has been achieved. By the carbonisation of coal, liquid products suitable for use in internal combustion engines or in furnaces can be obtained directly, but not in large quantities compared with the amount of coal used,

in such processes the greatest stress must be laid upon the markets for the solid and gaseous products, oil and petrol being merely by-products. By the hydrogenation of petroleum, or of low temperature tar and certain fractions of high temperature tar, large percentage yields of motor spirits can be obtained.

By the direct hydrogenation of a suitable coal some 160 gal of motor spirit per ton of coal treated can be made, and even when the additional coal for the process is taken into account the yield is 80 gal and the thermal efficiency is 43 per cent. Alternatively, motor spirit can be obtained synthetically either in the form of alcohols or of hydrocarbons, by first converting the coal into carbon monoxide and hydrogen, but not, under present conditions, so cheaply as by hydrogenation.

In view of the mechanical difficulties of working, on a large scale, a process involving simultaneously high pressures and high temperatures, the technical progress of coal hydrogenation has been surprisingly rapid. It is now undoubtedly possible to manufacture petrol from coal. The commercial prospects of the process are, nevertheless, uncertain, for it is always difficult to forecast the future of a synthetic, in competition with a natural, product.

### The Royal Academy

ENTERING the galleries of Burlington House with a mandate to seek for "points of particular scientific interest", I went first to the Sculpture Rooms, where my attention was arrested by the bust of Sir Patrick Geddes (1427), whose recent death has left a gap in the ranks of science which will not easily be filled. The character which emerges in Mr Pibworth's rendering is that of the acute analytical mind, the contemplative philosopher does not appear. It is interesting to consider in this connexion the appreciations which have appeared in the Press from a number of Geddes's friends, each reflecting a different facet of his many-sided mind. His influence in the world was undoubtedly due in large measure to the great variety of persons with whom he was able to make sympathetic contact.

The full-size model of the Native War Memorial, Lagos (1382), by Mr James A Stevenson, admirably illustrates the statuesque character which is so marked in many of the African peoples. I suggest that such successful generalisation of the attributes of existing races is of "more particular scientific interest" than the emphasis of simian characters, now so popular, which inevitably suggests the 'missing link' as the true ideal of the human form.

Among the oil paintings, well placed at the end of Gallery II, "Spoleto, Italy" (103), by Mr Osmund Pittman, is a fine composition, showing the hill town above a river spanned by an arched bridge (the water reflecting the colour of the sky), the architectural forms pleasing in the simplicity common to Mediterranean building, with plain plastered wall, small windows, low roofs, and ab-

sence of chimneys. In "Old Mill House, Avila, Spain" (150), by Mr Oliver Hall, R A, severity of architecture and a stern landscape are in fine accord, and the scheme of tone and colour is skilfully continued in the design of frame which this painter habitually employs.

"Last Rays Northern Ireland" (194), by Mr Julius Olsson, R A, is one of those studies of sunset colour upon the sea which cannot be too often repeated, for the effect is as fleeting as it is beautiful. Mr S J Lamorna Birch has a study of the columnar granite cliffs of the Land's End (225) rising from smooth, flat sands, across which the long, low waves come gliding in. "Harbour" (262), by Mr George Graham, recalls for our pleasure the perfection with which the forms of hull and sail, of spars and rigging, are outlined by the plain background of water and sky in the estuaries of a low-lying shore.

Mr Joseph Farquharson, R A, has a most poetic study of the stately columns of a fir forest among the mountains (339), with solemnity of deep, rich colour.

Mr Guy Kortright's "Springtime in Dalmatia" (557) and "August Heat Corsica" (623) are remarkable studies in the essential forms of the land, although not, I think, equally successful in conveying the transitory qualities of the seasons. "Twilight in the Downs" (604), by Mr William Clarkson, renders in a harmony of tones the mystery of the dying day.

Among the water-colours, Mr Frank Baker's "Widcombe-in-the-Moor" (781) gives us the ever-welcome scene of church and hamlet backed by swelling hills, seen in the soft sunshine of the

English summer In Gallery No VI, Mr Samuel Smith's dry point of "Richmond Castle, Yorkshire" (1165), is a fine study of architecture set between the water and the sky

The Architectural Room provides much food for thought. Looking at the dignified and harmonious designs of residential and business blocks

in framework of steel, we wonder why the appearance of our great cities is not more pleasing, and are impelled towards the hopeful conclusion that the source of our present discontent is the mixture of the cubical with the older, gabled forms; and that all may once more be well when the new pattern has complete possession VAUGHAN CORNISH

## News and Views

### Georges Cuvier

ON May 13 occurs the centenary of the death of the distinguished French naturalist and statesman, Baron Cuvier, often referred to as the founder of comparative anatomy "It was", says von Zittel, "the creative genius of Cuvier that erected Comparative Anatomy into an independent science, and defined principles upon which the investigation of fossil Vertebrates could be carried out with accuracy

... His greatness rests upon the magnificent work that he accomplished in the domain of Vertebrates, upon the scientific method which he founded for the identification of fossil bones, and upon his successful demonstration that the primeval mammals were not mere varieties of living forms, but belonged to extinct species and genera" Moreover, Cuvier, by his skill as a lecturer and writer and by his commanding personality, attracted many to the study of geology and palæontology, while, as one of the inspectors appointed by Napoleon to reorganise the schools and colleges of France and other countries, he did much to introduce and extend the teaching of natural history and other sciences

CUVIER, who was made a baron in 1819, was born on Aug 23, 1769, at Montbéliard, then belonging to the Duchy of Wurtemberg, his full name being Georges Léopold Chrétien Frédéric Dagobert Cuvier A child of unusual gifts, he received his earliest education from his mother, but at the age of fifteen years became a student at the Academy of Stuttgart, and at nineteen was a tutor in a nobleman's family in Normandy Here he passed the years of the Revolution, little affected by the events of the time, but meanwhile extending his knowledge of natural history The turning point in his career came with his friendship with the Abbé Tessier, through whom he went to Paris, where he quickly attained to a distinguished position In 1795 he was given a post in the Museum, in 1796 was made a member of the Institut de France, in 1800 he succeeded Daubenton at the Collège de France, and in 1803 he was made permanent secretary to the Academy of Sciences. His works included his "Leçons d'anatomie comparée" (1801-5), "L'Anatomie des mollusques" (1816), "Le Règne animal" (1817), "Les Ossements fossiles de quadrupèdes" (1821-24), and his uncompleted "Histoire naturelle des poissons" His *éloges*, published in three volumes, included those on Priestley, Banks, Delambre, Berthold, Lapeyère, and Davy For some years he was Chancellor of the University of Paris, and both under Napoleon and his successors he held high State appointments His

death was regarded as a national calamity, and his burial in the Père la Chaise cemetery was attended by a large concourse of people

### Portraits at the Royal Academy

IN addition to the paintings and other studies at the Royal Academy mentioned by Dr Vaughan Cornish in his article published elsewhere in this issue, the exhibits include portraits of the following Dr Alfred Cox, medical secretary to the British Medical Association, 1912-32 (190), by Sir Arthur Cope, Dr Thomas Sinclair, M.P. for the Queen's University of Belfast (210), by Mr George Harcourt, Prof Blair Bell, of the University of Liverpool (261), by Mr John A A Berrie, Prof R S Troup, director of the Imperial Forestry Institute, Oxford (332), by Mr Peter A Hay, Sir Robert Witt, vice-chairman of the Institute of Industrial Psychology (377), by Mr Oswald Birley, Dr W W Vaughan, headmaster of Rugby School, 1921-31 (398), by Mr Glyn Philpot; Mr F Howard Livens, vice-president of the Institution of Mechanical Engineers (447), by Mr Arthur G Walker, Dr Bevan Lean, headmaster of Sidcot, Somerset, 1902-30 (542), by Mr Bertram Priestman, Lieut-Gen the Right Hon J C Smuts, president in 1931 of the British Association (594), by Mr John Wheatley Among the statuary we notice Sir Ernest Shackleton (1390), statue, and Lord Melchett (1392), relief, both by Mr Sargeant Jagger, Sir Ambrose Fleming, emeritus professor of electrical engineering in the University of London (1492), bronze bust, by Mr George H Paulin, Sir Jagadis Chandra Bose, director of the Bose Research Institute, Calcutta (1564), bronze head, by Marguerite Milward

### Science in Drama

THE need for men of science to appreciate the sociological consequences of their work, alongside the equally vital necessity for politicians to realise what science opens up in the field of social and industrial reconstruction, have often been stressed in these columns. It is, therefore, with much interest that we note the production at the Globe Theatre, London, of "Wings over Europe", by Robert Nichols and Maurice Brown The authors avail themselves of a legitimate poetic licence A young and brilliant scientific worker with a rather simple sociological outlook discovers how to release the energy of the atom, and offers to present his discovery to the British cabinet, provided the cabinet will at once take such steps as should now be possible to eliminate poverty and reduce all work to the barest minimum The confusion and despair of a cabinet of men ignorant

of the elements of science and wedded to traditions that are now doomed is well portrayed, if rather exaggerated. That such a theme can find its place successfully on a London stage is significant of the fact that the importance of science as an unconscious revolutionary factor in society is beginning to be appreciated.

#### Scientific Precision and Popularisation

WHY is it that, in a certain class of publication aiming at popularity, vagueness seems to be considered essential in attracting the interest of the general public? It appears particularly in relation to geographical and ethnographical details. We have before us two small volumes from a series with many pleasing features, "Things Seen by the Camera" (London: George Routledge and Sons, Ltd., price 2s. 6d. net each). Of these, each contains sixty-four photographic reproductions. One deals with China and the Chinese, and another with the natives of Africa. The latter is concerned exclusively with physical types and covers a fairly representative range, some evidently chosen to demonstrate peculiarities of dress or physical deformation, such as the distension produced by the woman's lip-ornament. The volume dealing with China, in addition to characteristic or peculiar types, includes scenes from Chinese life and examples of Chinese buildings and architecture. It often happens that material of this kind is collected by those who have lived in out-of-the-way parts of the world and are not in touch with scientific bodies. They put their material in the hands of agencies, which distribute it to the popular Press, but through inadequate description, material which might be of value to the scientific worker not infrequently loses its utility. In fairness to the two publications before us, it must be said that in most instances they give an approximate or precise attribution. But if in one case, why not in all? "Witch-doctor from Central Africa", "Native Girl from Rhodesia", says little. The popular attraction of the picture could not possibly be affected by the addition or omission of the name of the tribe in brackets.

#### Britain's Contributions to World Progress

In a thoughtful essay entitled "The Projection of England" (London: Faber and Faber, Ltd., 1s.), Sir Stephen Tallents reminds us of our heritage of greatness in most fields of thought and activity, and points out that in the modern interdependence of nations, England can no longer afford to pursue a policy of standing aloof from the rest of the world. He indicates some of the attainments of the British in the fields of science and industry, and reflects that these are too little known to other nations. England neglects many opportunities of making herself known abroad, and of communicating her knowledge and discoveries to a wider world. In short, while he deprecates any form of national boasting, Sir Stephen Tallents argues that we need to develop "a continuous and sustained presentation of our industrial ability and our industrial ambitions through every available channel of communication open to us".

For this purpose, well-executed films are indispensable, but Sir Stephen presses for the art of national projection in a metaphorical as well as a literal sense. His proposal is that we should have a school of national projection—not as a government department, but rather as the result of private munificence—that must study national characteristics and achievements and lose no opportunity of suitably presenting these as records of fact to the wider world, through the medium of Press and poster, films and wireless, exhibitions and conferences. In these forms of enterprise, he complains that Britain has fallen behind some of the other great States of the world.

#### Trevithick's First Rail Locomotive

ON April 27, simultaneous meetings of the members of the Newcomen Society were held in London and New York. At both places, two papers were read, the first being by Mr. W. W. Mason on Trevithick's first rail locomotive, and the second by Mr. C. L. Chandler on early shipbuilding in Philadelphia. As the centenary of the death of Richard Trevithick would be commemorated next year, it seemed desirable, said Mr. Mason, to determine, so far as possible, the truth about the locomotive Trevithick built in 1803 and with which he experimented in South Wales in the early part of 1804. Neither the account of the experiment in Francis Trevithick's "Life" of his father nor those contained in other works agree as to the design of the engine, while there are discrepancies in the drawings in existence. One account, for example, says the cylinder was placed vertically within the boiler, while Llewellyn's drawing, preserved in the Science Museum, shows the cylinder horizontal. But this is only one point which calls for further investigation. Whatever doubt may exist as to the arrangement of the engine, however, there is little question that on Feb. 21, 1804, it took a load of 10 tons of bar iron and about 70 passengers from the Penydarran works, where it was constructed, down the old tram-road to its junction with the Glamorgan-shire Canal at Abercynon, a distance of about 10 miles, and in March repeated the journey, but with a net load of 25 tons. One of the most versatile inventors of his age, Trevithick was a pioneer in the use of high pressure steam, and by his experiment in 1804 he became the father of the steam locomotive.

#### Broadcast Reception in the United States

IN *World Radio* for April 15 there is an interesting account of a motor tour by R. M. Bell in the United States with a portable receiving set. As good highways connect all parts of the country, the 3000-mile trip from the Atlantic seaboard to Los Angeles can be made quite easily. The tour brought within daylight range most of the American stations. In Chicago the 25 local stations made it difficult to hear outside stations. Doubtless the same difficulty arises in New York, which has 43 local stations. Near Chicago, a relay from Poznań came through in excellent volume. There are nine television stations at present 'on the air'. Chicago uses 45 lines per picture and 15 pictures per second, New York uses

60 lines and 20 pictures per second. In Los Angeles, the 17 local broadcast stations, several of which are 'on the air' for 24 hours daily, made reception from other cities practically impossible, but a number of international relays from abroad were heard from them. The B.B.C. orchestra was heard as distinctly as it is in London. When passing through the Japanese and Mexican portion of the city, the street resounded with a speech from Berlin. In Tennessee, near Nashville, Los Angeles, 1775 miles to the west, and New York, 775 miles to the east, could be heard easily on the portable receiver. The writer mentions that Los Angeles (KFI), Dallas (WFAA), and Cincinnati (WLW) transmitted splendidly. In daytime they could be heard at a distance of 300 miles in good volume, and at night at distances of more than 1000 miles. When he got back to Pennsylvania, he heard at 7 A.M. the toasts given at the Lindbergh banquet at Tokyo (9 P.M. in Japan) being relayed from the local networks.

#### Ultra-short Wave Television

A SUCCESSFUL public demonstration of ultra-short wave television was given on Friday, April 29, at Messrs Selfridges' stores in Oxford Street, London. The transmitter was situated on the roof of the laboratories of Baird Television, Ltd., in Long Acre, W.C.2, the wave-length used being 6.1 metres. The ultra-short waves have the advantage over medium wave-lengths that they allow television pictures of much finer detail to be transmitted, and provide a reliable local service free from fading and atmospheric disturbances. An interesting feature of the transmission was that although sent out on ultra-short waves, the images could still be received easily by possessors of the ordinary Baird 'Televisor' and wireless sets of normal type designed for the present B.B.C. television transmissions. To do this, the only extra apparatus required was an ultra-short wave adaptor, which virtually converts any normal receiver into a super-heterodyne. The demonstration given on April 29 is the first public demonstration of the possibilities of ultra-short wave television to be given anywhere in the world, and marks a further stage in the development of the art.

#### Developments in Methods of Communication

A PAPER on modern communication systems, by Dr F. Luschen, was read to the Institution of Electrical Engineers on April 7. Dr Luschen pointed out that the rapid progress of invention has made modern communication systems very complicated to design. Few realise how difficult it was to solve the problem of the interconnexion of wired and wireless systems. This was first carried out in the telephone link between Great Britain and the United States. Further problems that have been solved are the multiple utilisation of lines for telegraphy and telephony, the control of electrical apparatus at a distance, and the electro-acoustic transmission problems involved in broadcasting and sound-films. These methods have widely extended the field of use of communication systems. The information

contained in the spoken word is an extremely complicated function of the time. The transmission system is composed of widely different elements. At first, therefore, it appears to be a hopelessly difficult problem. Yet, with the help of a few simple mathematical principles, engineers have succeeded in visualising the transmission of signals. As an illustration of the pitch of perfection to which carrier-current telephony has reached in the United States, Dr Luschen described a pole line carrying twenty pairs of conductors, sixteen of which carry three high frequency channels each, in addition to their low frequency communication circuits, while the other four pairs are equipped with ten telegraph channels each. Twenty pairs of wires thus result in 150 communication circuits, 80 of them being telegraph circuits and 70 of them telephone circuits. Dr Luschen also gave interesting particulars of tests made on a system of telephony and telegraphy linking Berlin with Buenos Aires. It is designed to transmit speech and two telegraphic messages simultaneously.

#### Rival Theories of Hearing

IN his Royal Institution discourse on Friday, April 29 on theories of hearing, Prof. H. Hartridge reminded his listeners that rivalry still exists between the theories of hearing, because the small size, the delicacy, and the inaccessibility of the internal ear make direct observation and experimentation well-nigh impossible. Some of the rival theories are the telephone theory, the modified telephone theory of Boring, the modified telephone theory of Watt, the volley theory of Wever and Bray, the pattern theory of Ewald, the stationary wave theory, and the resonance theory. At the present day, controversy principally centres round the resonance theory and some form of telephone theory. The production of deafness over a narrow range of frequencies, by surgical interference with a part of the internal ear, is accounted for more readily on the resonance theory than on the rival theory. The same may be said of boiler-makers' deafness and its experimentally produced counterpart. When physical tests are applied to hearing, evidence is obtained in each case in favour of resonance and contrary to telephony. The universal acceptance of the resonance theory is delayed by various criticisms, which arise in most cases from unfamiliarity with the behaviour of resonators and sense organs. The resonance theory accounts satisfactorily for all the phenomena, and no other theory does this.

#### Purpose in Evolution

IN the Riddell Memorial Lectures for 1931, delivered before the University of Durham at Armstrong College, Newcastle-on-Tyne, Sir J. Arthur Thomson discussed the general subject of "Purpose in Evolution" (Oxford University Press, 1932, pp. 59, 2s. 6d. net). The opening lecture examined various aspects of Nature in view of the question: Is there a purpose in evolution? It grants that often the development and ways of acting of living units are purposive, and comes to the conclusion that the scientific facts do

suggest the interpretation that Nature expresses a purpose, and that since the scientifically known system of Nature, being largely unconscious, cannot be credited with a purpose, we are led to think of a Creator's purpose. The fact that the scientific ideal is limited to a naturalistic description does not in the least imply that we need refrain from idealistic, transcendental, mystical, or religious interpretation—the only kind of interpretation there is. The second lecture dealt with the disharmonies in Nature and the difficulties to which they give rise in the teleological interpretation of a Creator's world, but such disharmonies, often exaggerated, need not obscure the greater fact of an overriding harmony. The final lecture, on "Lessons from Evolution", based on the fact of a real progress in organic evolution, is a plea for a ranging of human endeavour in line with the trends which have been conspicuously progressive in the re-human ascent of life.

#### Control of Canadian Insect Pests

THE Canadian Government and the Empire Marketing Board are jointly financing a search in Europe for the parasites of certain Canadian insect pests. The Canadian Department of Agriculture has asked the help of the Parasite Breeding Laboratory at Farnham Royal, Bucks, which is maintained by the Empire Marketing Board, in combating the present severe outbreak of a forest insect, *Diprion polytomum*, and also in fighting the plague of balsam woolly aphis, which is causing serious injury to balsam fir in the Maritime Provinces. If the balsam woolly aphis infection spreads throughout the eastern forests, as it threatens to do, enormous losses in pulpwood will result. The only hope seems to lie in the introduction of a parasite to check the advance of the aphis. The pest came originally from Europe, but it is not common, and an intensive search will have to be made in Central Europe to find its insect parasites. These insects will then be brought to England and bred up at the Farnham Royal laboratories. Nearly one million insect parasites have been bred and dispatched from time to time from Farnham Royal to all parts of the Empire. The wheat-stem sawfly, one of the Western farmers' major problems, is now being investigated. Officers of the Imperial Institute of Entomology have collected parasites in France and bred them up in England. Last season several large consignments of broken wheat straw, containing sawflies plus parasites, were packed in special boxes and shipped to Canada. These parasites have been released in the wheatfields, and up to date are doing well.

#### Blanching of a Bay Horse

In the *Field* for April 16, p. 582, Miss J. McAlpine gives an account of a bay horse the mane of which, black as usual in this colour, turned nearly white owing to a severe fright it received at six years of age when out at grass in a very long field. An aviator, in trying to land here, drove the horse the whole length of the field, and nearly alighted on it. No one saw the horse for three days afterwards, but it was then found to have lost the colour of its mane, as described,

while the tail had also become quite grey. A photograph of the animal, now nine years old, accompanies the note, and shows the pale mane very plainly, so that the effect of the shock seems to have been permanent. The writer of this note once casually saw in a London street a bay pony with a grey mane and also an angular grey patch let in, as it were, on the brown short hair of the neck, but put it down to a freak of variation. The horse is more liable to variation in pelage than any other domestic mammal, and another bay, an aged van-horse, also seen casually in London, was spotted with white over the brown parts as clearly as any deer, but with smaller, more angular spots.

#### Frequency of Insects in the Air

AMONG a recent series of "Why the Weather" articles by C. F. Talman, issued by Science Service, there is one article commenting on some experiments made in France by A. Bonnet to determine what that meteorologist called the 'entomological density' of the air, a few feet above the ground. This quantity, defined as the number of insects in a cubic metre, was obtained by means of a muslin net attached to the front of a motor car. The car was driven for a kilometre in unfrequented regions far from places where insects collect in exceptional numbers, and the insects in a 1000 cubic metre sample of air were collected and counted. The density was found generally to vary from one or two at sunrise to about seventy in the early afternoon, with a subsequent decline to one or two again at sunset. Those species normally found only very early and late tended to appear in the middle of the day when the air was nearly saturated. This is a line of research that might appeal to motoring meteorologists. It would be interesting to trace the effect of the insect density upon visibility, and see to what extent some of our midsummer hazes are due to large values of this quantity.

#### Orthographical Relief

A NEW method of showing surface relief on a topographical map is described by Prof. T. Kiturô in the *Geographical Journal* for March. The inventor claims this to be a natural, in contrast to a conventional, method, since it is based on the principle of shading, and gives the reader the appearance of the land rather than detached information of heights. The method makes use of what Prof. Kiturô calls the 'inclined contour'. This is defined as the projection upon a datum plane of the outline of the intersection of the ground surface with an inclined plane. By contrast, the ordinary contour, which is distinguished as the horizontal contour, is the projection upon a datum plane of the intersection line of the ground surface with a horizontal plane. The inclination of the inclined plane is assumed to be 45°. The effect of these inclined contours is to give a shaded map of relief features with a southern illumination on the specimen of a Japanese map which is reproduced. The thickness of the inclined contours is constant, and after experiment it was found most useful to have between thirty and seventy lines to the centimetre.

The method of drawing these contours from the ordinary contoured map is fully described. One obvious disadvantage is that they give a dark map, but this might be overcome by drawing the contours in grey or buff. The finished map certainly gives a striking picture of relief where the slopes are steep.

#### Sugar Cane Research

THE Report of the proceedings of the Imperial Sugar Cane Research Conference, held in London in July 1931, has recently been issued by H. M. Stationery Office (price 2s 6d net). The conference, to which reference has already been made in NATURE (July 25, p. 160) was convened by the Empire Marketing Board to discuss the future of scientific research in sugar cane production, but it was decided that the world economic position should be considered in drawing up a research programme. As a result, some seventy pages of the report give a review of the economic position of the industry, which contains many valuable facts and figures. The present organisation of research within the British Empire is considered in some detail in reference to the various cane sugar growing areas, after a brief general introduction by Dr P. S. Hudson that deals mainly with the genetical side of the problem. Dr. Hudson concludes that whilst some early advances have been made, and still may be expected, the full utilisation of scientific methods in breeding, which involves a cytological study of the genetical material, can alone lead to continued progress and development in this line of work, which is of so much importance in developing Empire resources. Dr. W. R. Thompson points out that, owing to the wide range of habitat in which sugar cane can be successfully grown, it suffers from an unusually large list of insect parasites. With some of these, such as the leaf frog hopper in Hawaii, a very great measure of success in combating them has been obtained by using the method of biological control. Dr. Thompson states that the method of biological control has this great advantage that, when it can be successfully applied, it provides what is practically permanent relief at a relatively small initial cost.

#### Evaluating Periodicities by Machinery

THE application of Fourier's harmonic analysis to weather phenomena has revealed many outstanding periodicities. To those who feel that the next step should be directed towards understanding the cause of these periodicities, rather than the evaluation of yet more, the invention of mechanical aids to 'periodicity hunting', such as Abbot's periodometer, will naturally make little appeal (Smithsonian Miscell. Coll., vol. 87, No. 4 (Pub. 3138)). "The Periodometer, an Instrument for Finding and Evaluating Periodicities in Long Series of Observations." By Dr. C. G. Abbot. The device is one for avoiding numerical computation in studies of this kind. It does not detect periodicities, that has to be done by inspection of the statistical material. This step involves a personal factor. Given any suspected periodicity, the machine shows to what extent this appears consistently throughout the material, and determines

the shape of the curve of variation of the element over this period. The reality of the periodicity is judged from the shape of this curve. Having decided that it is real, the operator is then able, with the aid of the machine, to eliminate this periodic variation, and so gets a residual curve that is scrutinised afresh for other periodicities. The curve of variation may depart widely from a simple sine curve, and this method of analysis therefore differs from the classical Fourier process, and on account of the presence of the personal factor will give different results when different workers use the same material. The ultimate test of merit is, of course, whether the method will lead to greater knowledge of underlying physical causes, and it remains to be seen whether this will be the case. The cost of production of the first periodometer was apparently a thousand dollars, the money being provided by the Research Corporation of New York.

#### Chemistry and Action of Drugs

In his Lane Lectures on pharmacology, Prof. W. Straub, of Munich, discusses certain problems of general interest in the chemistry, synthesis, and action of drugs (Stanford University Publications, University Series, Medical Sciences, vol. 3, No. 1, 1931, London: Humphrey Milford). Two are devoted to digitalis, the chemistry of the glucosides of the leaf and their physiological action being reviewed. Prof. Straub points out that the differences in action of the glucosides of the cardiac tonics, digitalis, strophanthus, and squill, can be explained to a great extent by a knowledge of the speed with which they are taken up by the tissues of the body as well as by the heart, and of the ease or difficulty with which they can be afterwards destroyed. The greater response of the pathological, as compared with the normal, heart to digitalis can be similarly explained, since the slowing of the circulation permits of a greater absorption of the drug by the tissues. These lectures were primarily addressed to pharmacologists. Three subjects were chosen as of interest to students and physicians, anaesthesia, the pharmacology of the heavy metals, and the camphor problem. In the latter lecture Prof. Straub discusses the attempts made to prepare a synthetic compound having similar stimulant effects to camphor on a failing heart and respiration without its disadvantage of slow absorption after injection. Cardiazole (pentamethylene tetrazole) appears to fulfil the requirements best at the present time; it is more soluble in water than in oil, so that it will be rapidly absorbed, but its oil insolubility will ensure that it exerts a stimulant rather than a narcotic action on the central nervous system. The sixth lecture, addressed to a scientific audience without medical interests, dealt with certain general problems of the use of intoxicating drugs.

#### Reconstruction of Tokyo and Yokohama

DURING the seven years that followed the great earthquake of Sept. 1, 1923, the rebuilding of Tokyo and Yokohama was practically completed, at a cost of nearly eighty-five million pounds. M. Jean Gracy has written a full account of the renovated cities, of

which a summary is given in the last number of the *Matériaux pour l'Étude des Calamités* (pp 156-165, 1931). The total area appropriated for new streets and parks is 914 acres in Tokyo and 89 acres in Yokohama, and of this, one-tenth was taken from the previous owners without compensation. In Tokyo, three classes of streets have been laid down. In those with much traffic, the total length is 73 miles; no street is less than 80 ft wide, and some for short distances are as much as 108 ft and 144 ft, and one even 252 ft wide. Those with a moderate amount of traffic have a total length of 86 miles and a width varying from 36 ft to 72 ft. Four hundred bridges have been restored so as to resist both fire and earthquakes. The value of open spaces was well shown in 1923. Accordingly, three large parks have been made with a total area of nearly 50 acres, and 51 small ones with an area of 37 acres, the latter being usually near primary schools, for which they serve as playgrounds.

#### Absorption Spectrophotometry

MESSRS Adam Hilger, Ltd, 98 King's Road, London, N W 1, have issued a bound book of eighty pages dealing with the theory and practice of absorption spectroscopy (price 5s net, postage 3d). It contains a brief theoretical introduction, then thirty-two pages of description of Hilger apparatus and description of technique, including work in the ultra-violet, visible, and infra-red regions, with a note on photoelectric methods, and the rest of the book deals with applications, particular attention being directed to biological aspects and analysis. This contains references to original literature. A companion volume, entitled "Recent Applications of Absorption Spectroscopy" (price, bound, 3s 6d, postage 2d), published by Messrs. Hilger, provides a very complete and carefully classified account of the literature from 1922 to 1931, with useful notes. The two publications form a handy yet compendious guide to the practice and literature of spectrophotometry in all parts of the optical spectrum, and may be recommended to all interested in this branch of science.

#### Health of the Navy in 1930

THE health of the Navy during 1930 appears to have been remarkably good, judging by the details contained in the "Statistical Report" for the year, recently issued by the Admiralty (London. H M Stationery Office 2s 6d net). The total number of cases of disease and injury in a force of 88,840 men was 38,031, a marked decrease on the previous year and in comparison with the five years' average. Venereal diseases head the list of admissions with 5154 cases, respiratory catarrhs (4378 cases) and tonsillitis (2429 cases) coming next, apart from local injuries and wounds, which numbered 7238 cases. There were only 36 cases of alcoholism, 11 cases of typhoid and paratyphoid fevers, and 5 cases of Mediterranean fever.

#### Announcements

THE Masters' Memorial Lectures of the Royal Horticultural Society will be delivered in the lecture

room of the Society's new hall in Greycoat Street, Westminster, on May 10 and 11, at 3 30 P.M., by Sir Frederick Keeble, on "Garden Fertility. its Origin and Maintenance"

THE Royal Society of Edinburgh announces that the Keith Prize for the period 1929-31 has been awarded by the Council to Dr A W Greenwood, lecturer in the Institute of Animal Genetics, University of Edinburgh, for papers on the biology of the fowl, and the Neill Prize for the period 1929-31 to Dr C H O'Donoghue, reader in zoology in the University of Edinburgh, for papers on the blood vascular system, and for earlier work on the morphology of the *corpus luteum*.

LIEUT -COL F C SHELMEKDINE, Director of Civil Aviation, opened an exhibition of aerial photographs by Aerofilms, Ltd, on Tuesday, May 3, at the Camera Club, 17 John Street, Adelphi, W C 2. The exhibition will remain open to the public until May 31 daily from noon until 6 P.M. Examples are shown of the application of aerial photography to archaeological and geological research, general survey work, town planning, and many other problems.

*Australian Science Abstracts*, a quarterly publication issued by the Australian National Research Council, Sydney, is a useful guide to investigations dealing with many aspects of Australian scientific activity—anthropology, zoology, botany, and physiology, veterinary science, agriculture, and economics, geology, geography, chemistry, and engineering. The subscription price is 4s a year, including postage.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—An assistant physicist in the Radiological Department of the Cancer Hospital, Fulham Road.—The Secretary, Cancer Hospital (Free), Fulham Road, S W (May 12). A full-time teacher, mainly for science or mathematics in the Junior Technical School, Horwich, and for engineering subjects in the Technical College.—The Secretary, Railway Mechanics' Institute, Horwich (May 13). A pathologist for certain of the Liverpool Corporation Hospitals.—The Town Clerk, Municipal Offices, Liverpool (May 14). A director of education of the Polytechnic, Regent Street.—The Clerk to the Governors, The Polytechnic, 309 Regent Street, W 1 (May 21). A principal of the Cordwainers' Technical College.—The Clerk to the Board of Management, Cordwainers' Hall, 7 Cannon Street, E C 4 (May 24). An assistant keeper on the higher staff of the Victoria and Albert Museum.—The Director and Secretary, Victoria and Albert Museum, South Kensington, S W 7 (May 31). Assistant lecturers in, respectively, philosophy and physics at the University College of Swansea.—The Registrar, University College, Singleton Park, Swansea (June 4). A student probationer (zoologist or physiologist) at the Marine Biological Laboratory, Plymouth.—The Director, Marine Biological Laboratory, Plymouth (June 10). A borough electrical engineer to the Durban (South Africa) Corporation.—The Town Clerk's Office, Durban, Natal, South Africa (July 15).

## Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

### Action of the Alkaloids and Carbon Monoxide on the Enzymatic Activity of Plants

IN a series of investigations which I began during 1929<sup>1</sup> I was able to demonstrate, with the help of my collaborators, that the debatable question of the function of alkaloids in plants could be profitably examined by investigating the various enzymatic activities, beginning with those of germinating seeds.

The first case that I examined was that of barley in which exists, as is well known, an increasing activity of amylase with increase of germination. Beside, I noticed a net augmentation of activity due to the addition of dilute solutions of strychnine nitrate. In turn<sup>2</sup> the activities of lipase, amylase, protease, and oxidase were measured in castor oil seeds germinating in pure water and in strychnine nitrate solutions of different concentrations. In every case the addition of strychnine at the concentration optimum of 1 per thousand causes an increase of activity. It should be noted that this increase is not due to action of the alkaloid on the enzymes already formed, because the effect is not observed with the enzymatic extracts of seeds.

The amount of increase of the activity is different, the most sensible effects being in lipase and oxidase. The effect of alkaloids being consequently selective for different enzymatic activities explains, in my opinion, why they do not always help the growth of plants, in effect, they can determine a want of equilibrium in the various biochemical activities, which for full growth of the plant we suppose must be properly proportioned. Investigations showed that the *Ricinus* seedlings, that were followed for a month during their germination, showed constant improvement, by the addition of solutions of strychnine nitrate. The alkaloid contained in the bark of the *Ricinus* seeds, ricinine, has shown itself necessary for the germination, but strychnine can be substituted for it. Caffeine has also been found to be advantageous up to an advanced age, but this is an isolated fact, because this alkaloid is toxic for barley, flax, and other plants. From the observed facts, the opinion that alkaloids must be considered as hormones of the plants is strengthened.

My researches show that carbon monoxide itself alters in a sensible way the enzymatic activities of plants. This gas, also in small quantities, stops the assimilatory activity of green plants in light, but not the respiration (oxidase), so it was supposed that it also had selective action on the enzymatic secretions.<sup>3</sup> It was effectively shown that carbon monoxide depresses amylase activity of barley and of *Ricinus* powerfully, while in the same *Ricinus* it increases slightly the lipase activity. In consequence, the behaviour of the gas during the germination of seeds was to be expected to be irregular, thus it was found that while wheat is able to germinate in an atmosphere rich in carbon monoxide, the field cabbage and hemp only germinate with great difficulty, while flax and tomato do not germinate at all. Leguminous plants, such as lupin and pea, showed special behaviour: they are able to germinate in an atmosphere rich in carbon monoxide, and also if the operation is accomplished under a cover with seeds

made sterile a considerable absorption of nitrogen which causes much depression is observed.<sup>4</sup>

The determination of the contained combined nitrogen denoted an increase from 20 to 40 per cent in a few days. This fact combined with the selective action of carbon monoxide and of alkaloids on the enzymatic activity of germinating seeds makes one believe that the nitrogen assimilation in leguminous plants, as other authors have supposed, is due to the stimulating action of nitrogen bacteria, but not exclusively to these bacteria. The nitrogen assimilation is related to enzymatic activities which are latent in leguminous plants. In further confirmation of this are the new investigations that we are making now, from which it appears that the alkaloids also are able to promote nitrogen assimilation by lupins and peas.

The other effects, observed up to now in different seeds, in relation to different enzymatic activities, are summarised in the accompanying table.

| Seed           | Exciting Substance                | Percentage Variation of the Enzymatic Activity |             |         |          |
|----------------|-----------------------------------|------------------------------------------------|-------------|---------|----------|
|                |                                   | Lipase                                         | Per-oxidase | Amylase | Protease |
| <i>Ricinus</i> | Carbon monoxide (50 per cent air) | +5                                             |             | -70     |          |
| "              | Strych 1 $\frac{1}{1000}$ pH=4.6  | +20                                            | +150        | +4      | +10      |
| "              | Strych 1 $\frac{1}{1000}$ pH=6.8  | from +50 to +250                               |             |         |          |
| "              | Ricinine 1 $\frac{1}{1000}$       | +30                                            |             |         |          |
| Barley         | Caffeine 0.5 $\frac{1}{1000}$     |                                                |             | -20     |          |
| "              | Strych 0.5 $\frac{1}{1000}$       |                                                |             | +80     |          |
| "              | Carbon monoxide                   |                                                |             | -70     |          |

Investigations on these lines are being continued in this Institute, and will be extended to other kinds of plants and alkaloids.

### Colour Response in a Leech

COLOUR change in response to environmental conditions has been described in the following groups: vertebrates, crustaceans, and certain molluscs. There are two types of mechanism by which rapid redistribution of the pigment in the skin is brought about. In molluscs, the pigment is contained in minute elastic bags, which can be expanded by means of a specially arranged musculature, and contract because of their own elasticity. In crustaceans and vertebrates, the pigment is present as granules inside stellate cells, and can migrate through the protoplasm, being either localised in the centre of the cell or distributed more or less evenly through its processes.

The common fresh-water leech *Glossosiphonia complanata* has conspicuous stellate cells in its skin, containing brown or black pigment. I have observed that the pigment in these cells undergoes changes in configuration, contracting together if the animal is kept in total darkness, and spreading out into the stellate shape if it is kept in light. They are therefore chromatophores of the vertebrate-crustacean type. Curiously enough, they are so few and so widely spaced that their activity has little or no effect on the general coloration of the leech.

The accompanying photographs (Fig. 1) were obtained as follows. A number of leeches were kept in darkness for several days, and then pairs were selected, the two members of each pair having chromatophores in the same state of expansion. One member of each pair was kept in daylight for a day, while the other was put back into darkness. They were then fixed, mounted whole in balsam, and photographed. The upper photograph shows a group of chromatophores from the illuminated member of such a pair, and the

FIG. 1.

lower is a group from its fellow kept in darkness. The scale line on the lower picture represents 0.3 mm.

Hogben and Slome<sup>1</sup> have shown that there are two distinct modes of response to light in vertebrate chromatophores:

(1) 'Primary Reactivity': expansion in light, and contraction in darkness. This response is seen in blinded animals, and is probably a direct effect of the light on the chromatophores themselves.

(2) 'Secondary Reactivity': expansion when the animal is illuminated on a dark background, and contraction when it is illuminated on a pale background. This is a complex response, involving the eyes and a co-ordinating mechanism, and is superposed on the first.

Preliminary experiments have revealed no response

to background in *Glossosiphonia*, which apparently presents the primary mode of response alone and uncomplicated by the secondary. G. H. Parker<sup>2</sup> has recently pointed out that in vertebrates, crustaceans, and cephalopods the visual organs are highly developed, and suggests that colour change has only evolved in groups in which the eye is capable of distinguishing the details of the luminous environment. It is therefore interesting to note that a chromatophoral mechanism exists in an animal with eyes of extremely simple construction, and that it is of the mode which, in vertebrates, does not depend upon the visual organs. Prof. Parker's generalisation remains valid if it is restricted to secondary reactivity, that is, to colour change in response to background.

The physiology of the response and its possible occurrence in other leeches are being investigated.

#### Is Preformed Cystine Essential to Sheep for Wool Production?

IN a recent paper<sup>1</sup> attention has again been directed to the fact that the proteins of pasture grass contain only exceedingly small quantities of the sulphur-containing amino-acid cystine.<sup>2</sup> As Evans points out, sheep's wool is relatively rich in sulphur, and this, it has been shown, is almost exclusively present as cystine<sup>3</sup> (13 per cent by weight of cystine may be taken as an average figure for wool keratin).

Since cystine has always been regarded as an 'essential' amino-acid which the animal body is unable to synthesise, it becomes of interest to calculate the amount of food necessary to produce a year's growth of wool. A 12 lb. fleece may be assumed to yield 6 lb. of clean wool, containing 0.78 lb. of cystine. Putting the cystine content of pasture herbage, which comprises the main part of a sheep's daily ration in many parts of the world, at 0.01 per cent on weight of dry matter, and, for the sake of argument, assuming that none of this cystine is katabolised and excreted, it follows that an animal must eat 21.4 lb. of dry grass per day, or about 60 lb. of fresh pasture—an impossible amount, since a normal, fully grown sheep under optimal conditions will consume only about 4 lb. per day.

The wool research workers in Australia under the late Prof. Brailsford Robertson assumed that the quantity of cystine available in the diet of sheep must be a factor limiting the quantity of wool they can produce.<sup>4</sup> The sulphur content of wool is not fixed, however, but variable,<sup>5, 6</sup> and it appears that the sulphur content (cystine content) of wool grown during periods of adequate nutrition, for example, after rains when the pasture is lush, is higher than that grown during periods of scarcity.<sup>6</sup>

In Bonsma's experiments, controlled feeding on maize meal (poor in cystine) over a whole year failed, however, to bring about either marked decrease in fleece weight or in sulphur content of the wool grown. It would appear that more cystine is used in producing wool than can be accounted for in the food eaten.

Evans concludes, as have others, that there must be present in the diet some substance closely related to cystine from which the latter can be synthesised. Neither cysteic acid,<sup>7</sup> taurine,<sup>8, 9</sup> sulphates, elementary sulphur,<sup>10</sup> dithio-glycollic acid, or dithio-dipropionic acid, in spite of their close chemical resemblance to cystine,<sup>11</sup> nor any other compound (with the exception

of cystine peptides) has ever been reported in the literature as capable of replacing cystine in the diet.

It would appear, however, that no strict feeding experiment, keeping a cystine and sulphur balance-sheet, has ever been performed upon a sheep—the assumption that cystine cannot be synthesised being borrowed from experience with laboratory animals.<sup>12, 13, 14</sup> It is the purpose of this note to point out that the two cases are entirely dissimilar, and to suggest a very plausible manner in which the cystine requirements of sheep can be met whilst on a cystine-deficient diet which contains, however, sufficient other sulphur-containing compounds.

The mouse, rat, and guinea-pig are omnivora, characterised by quick metabolism, whilst the sheep is a herbivorous animal, in the gut of which bacterial activity plays a very important rôle.

It is customary in nutritional work upon sheep to allow 6-8 days for the complete passage of the ingesta through the alimentary canal. The intestinal flora and fauna (bacteria, yeasts, etc.) are almost certainly able to synthesise cystine from inorganic sulphur and it is conceivable that the population of the sheep's intestine, by continual increase, is transforming sulphates into cystine, built into their own protoplasm, with a high grade of efficiency. As bacteria die, their cell protoplasm autolyses, again setting free the sulphur, now in the form of cystine, which is readily available to the sheep.

That the metabolism of an ingested product does actually follow a different course in carnivora and in herbivora has been demonstrated in the case of taurine by the experiments of Schmidt and Clark<sup>15</sup> and of Salkowski.<sup>16</sup> It is computed that in man about 8 gm. of bacteria are excreted in the faeces daily, and this number will almost certainly be much higher in the case of the sheep, so that from the quantitative point of view the above argument is satisfactory. Some experiments are being planned at the Onderstepoort Laboratory to put our hypothesis to the test.

It seems to us of the utmost importance that this question should be thoroughly investigated, and the availability or otherwise of simple sulphur compounds for wool production by the sheep settled beyond all doubt. Otherwise, there is a danger that whole schemata of nutritional research and of advice to the pastoralists in two continents may rest upon no surer foundation than an unjustifiable assumption.

### Inheritance of Milking Capacity

I SUBMIT that on the evidence available Mr. Madsen<sup>1</sup> was justified in reaching the tentative conclusion, that some of the genetic factors governing milking capacity are transmitted in a sex-linked manner, and that the points mentioned by Mr. Edwards<sup>2</sup> in his letter are based upon a misapprehension of the subject. Mr.

Edwards states two objections, but if his first one be analysed it will be seen to contain three different points, so that all Mr. Edwards's objections to the conclusion reached by Mr. Madsen may be summarised as follows:

1. That the sires are selected by genotype, rather than phenotype.
2. That the record of a single cow is insufficient in foretelling the production of her progeny.
3. "... it is doubtful if one should expect to find a significant difference in the correlations of two such records diluted through three generations."
4. That the difference between the two correlation coefficients is not significant, and that such a difference would be likely to occur by chance once in ten times.

The logic on which the first objection is based is not clear. How does the method employed in the selection of the sires affect the grandams? Would Mr. Edwards argue that those cows which are mated to bulls selected by genotype are of a different order from cows mated to bulls selected on phenotype? Or would he argue that since the sires of the bulls involved are selected on their genotypes, therefore their dams are of a different order from the maternal grandams of the bulls in question? In any event, when the full paper is published, Mr. Madsen will show that the majority of the sires involved have not been selected on genotype, but on appearance plus pedigree.

As to the second objection, Mr. Edwards should know that dairy cattle are extremely heterozygous for the factors governing the transmission of milking capacity; and further, that it is the exception for the genotype of a cow to be assessed in respect of milk yield, because her offspring are few and seldom all sired by the same bull. It is not to be expected that the records of a single cow will be of great value in foretelling the production of her progeny by another bull. I would point out that a statistical study is based on the average of a large number.

Mr. Madsen in his letter was particularly careful to stress the fact that the *genotypes* of the male, but the *phenotypes* of the female, ancestors were being compared to the genotypes of their sons and grandsons, and that consequently correlations to the female ancestry were in a category by themselves. Both of Mr. Edwards's objections seem to be based on a misunderstanding of Mr. Madsen's statements.

The third objection is based on the speculation that, with the material used by Mr. Madsen, no correlation to the grandams was to be expected. Incidentally, this was also my own expectation. But Mr. Madsen has shown that this is not so. Despite the inevitable drawbacks of his method, he has given good reason to believe that there is a small but significant correlation to the maternal grandam, while the slight positive correlation to the paternal grandam is insignificant. Mr. Edwards is scarcely justified in upholding speculation against ascertained fact.

The last objection refers to the value of the standard error. If the study were to be contained within reasonable limits, an error of such value was unavoidable. Actually more than 100,000 lactations had been analysed and classified. Mr. Madsen's conclusions are based not merely on his own work, but also on the material contained in the paper by myself, Scott and Fowler,<sup>3</sup> which he quotes, and, by implication, on the work of Gowen, to which reference is made in our paper. Mr. Madsen was also acquainted with other papers dealing with this subject, including the most recent one from this Institute,<sup>4</sup> which presents a case for the possibility that certain of the genetic factors controlling milk production are inherited in a sex-

linked manner. Any one of these several investigations alone might be insufficient for drawing such a deduction, but when what Mr. Edwards calls one chance in ten recurs repeatedly, it is surely not illogical to presume that it has some significance, and to try to interpret the facts. Of all possible explanations, sex-linkage is not only the simplest, but also the most reasonable.

I should like also to correct an error on the part of Mr. Edwards. If he will re-calculate the figures carefully, remembering that he is dealing with a *standard* error of  $\pm 0.03$ , he will find that the results would be likely to occur by chance, not once in ten times, as he states, but once in twenty. I leave it to others to determine whether this difference is significant.

Finally, I may take this opportunity of congratulating Mr. Madsen on his study, which is in some respects the most comprehensive of this nature that has as yet been made. His material is unique and his results give considerable food for thought. It is to be regretted that funds for such research, both in Britain and in Denmark, have been recently curtailed, so that the publication of the full paper has been considerably delayed.

#### Vocal Powers and Eyes of Kangaroos

MR. FINLAYSON<sup>1</sup> quite rightly corrects the statement that kangaroos are never known to utter any sound normally. I have in Melbourne, four miles from the Melbourne Post Office, at my home, two large grey kangaroos and eight wallabies. I have kept such animals for years, by reason of an investigation undertaken long since into the refractive condition of the eyes of the monotremes and marsupials and of mammalia generally.

Of the three sounds Mr. Finlayson refers to, I have heard two frequently. These ten animals are fed in the morning, and when they are hungry they have minor differences amongst themselves, and the kangaroos frequently make a sort of grunt or growl if they think that their food is being interfered with. The bark or cough is quite distinct. It may be a warning signal to kangaroos, but it is certainly a danger signal as regards human beings. Whether from gout or old age or something of the sort, the old male kangaroo occasionally becomes disagreeable, and the bark or cough, or what appears to be a bark or cough, is a warning to a human being—a warning which, if he is wise, he will heed—to keep away. The greatest danger comes from tame kangaroos, because they have no fear of man. I bred a very fine specimen of *Macropus Giganteus*, which later on became so dangerous, as we gathered from the continual barking, that I had to have him transferred to the Zoo. I have never known a female kangaroo to show any desire to attack, but on one occasion when some children were petting a baby kangaroo, just out of the pouch, the mother gave a soft growl, or what sounded like it.

Whilst writing, I may direct attention to the fact that I have not been able to obtain a good estimate of the refractive character or of the accommodation of the eyes of kangaroos or wallabies. In the case of some of the monotremes and the smaller marsupials the work has been done, and a note appears in the

*Medical Journal of Australia* for Feb. 6, 1932, summarising the result.

Subject to an investigation of the kangaroos, which is very difficult owing to their size and the difficulty of handling them, the result is that the eyes of the animals referred to are imperfect as optical instruments, and there is no evidence that they accommodate at all. Throughout the mammals, until the primates are reached, accommodation is rudimentary or absent, and the ciliary muscle is variable or rudimentary in amount. This capricious development, or want of development, of accommodation in these creatures opens up the fundamental riddle from the point of view of evolution. Why these animals should have rudimentary accommodation and a variable ciliary muscle, which can be of no real service—especially in some cases owing to the gross error of refraction in their eyes—so far appears to be an insolvable puzzle.

Those who have read Prof. W. A. Osborne's recent article on accommodation in the animal kingdom and Prof. Wood Jones's Bancroft lecture, both published in the *Medical Journal of Australia*, 1931, will realise the extraordinary complexity of the problem which accommodation in animals presents. I hope it will be possible to investigate accommodation in kangaroos, but this involves the capture of the animal, the maintenance of his life, and the frequent use of anaesthetics.

#### Types of Iridescent Clouds

THE remarkable clouds at high altitude which have been the subject of two interesting articles by Prof. Carl Størmer<sup>1</sup> and Prof. S. Chapman<sup>2</sup> in *NATURE* are referred to as iridescent or mother-of-pearl clouds. In order to prevent misunderstanding, I should like to point out that the high clouds in question should not be confused with the much more common 'iridescent clouds' which are described in most textbooks of meteorology.<sup>3</sup> The latter are cirro-stratus or cirro-cumulus clouds and are certainly well within the troposphere, at a height of approximately 10,000 metres, while the clouds described by Størmer are two or three times as high and are well within the stratosphere.

While the high clouds in the stratosphere can be confused with much lower clouds on account of the use of the adjective 'iridescent', they can also be confused with another type of cloud because of the use of the adjective 'high'. Occasionally, generally after violent volcanic eruptions, bright clouds can be seen long after sunset, showing that they are at a great altitude. Prof. O. Jesse has determined the height of these 'luminous night clouds' to be between 70 and 80 kilometres, and they are, therefore, much higher than the high iridescent clouds described by Størmer and Chapman, both of whom are careful to warn their readers against confusing the two types of high cloud.

There are then three types of clouds which have to be carefully distinguished: (1) iridescent clouds in the troposphere at 10 kilometres, (2) high iridescent clouds in the stratosphere at 20-30 kilometres, and (3) high luminous night clouds at 70-80 kilometres. The physical composition of these three types of clouds is an interesting problem. In order to explain the brilliant colours on the iridescent clouds of the troposphere, it is necessary to assume that in spite of the low temperature at which they occur (about  $-40^{\circ}\text{C}$ ), these clouds are composed of super-cooled water.

drops, or at least of small spheres, and not of crystals<sup>4</sup>. The same reasoning would indicate that the iridescent clouds of the stratosphere are also composed of drops, but there is so little water vapour in the stratosphere that it is difficult to see how clouds of the density described by Størmer can be formed.

The high luminous night clouds are supposed to derive their water from the volcanic eruptions with which they appear to be associated—they were particularly bright from 1883 to 1889 after the Krakatoa eruption—but the close association of the iridescent stratosphere clouds with a particular type of weather appears to make this explanation unsuitable for them.

It is quite clear that there is still a great deal to learn about the physical state of the upper atmosphere.

<sup>4</sup> Simpson, *Quar. J. Roy. Met. Soc.*, 38, 291, 1912

IN NATURE of April 2, Prof Chapman has an interesting article on the iridescent (mother-of-pearl) clouds observed by Prof Størmer of Oslo. These clouds, which are unmistakable in appearance, are reported to have been at the great height of 26 to 30 km. I once discussed these clouds with the late Prof Mohn, but there was then no suggestion that they floated so high. Their appearance at the altitude now recorded opens up some interesting problems.

The clouds are to be seen from time to time at sea. It was my custom to call them 'fish-scale colour clouds' and to associate them with bad weather.

The reports of luminous 'night clouds' have always puzzled me, and although I spent a great deal of time in the open air, I have never seen them, nor have I ever met any seaman who has. Is it possible, however, that there may be some connexion between this great altitude and luminosity?

#### Hexuronic Acid as the Antiscorbutic Factor

WE have reported in a previous note,<sup>1</sup> that with a daily dosage of 1 mgm hexuronic acid guinea-pigs were kept free from symptoms of scurvy for fifty-five days. This experiment was continued to the ninetyeth day. During this time all animals receiving hexuronic acid showed normal growth. On the ninetyeth day all animals were chloroformed, and on autopsy were found entirely free from scurvy. The animals receiving 1 c.c. of lemon juice showed mild scurvy. The experiment was completed with all the necessary controls.

Since the hexuronic acid used was prepared from animal sources (adrenal glands), no objection can arise that the observed antiscorbutic activity was due to a contamination by a more potent antiscorbutic substance. The daily dose of hexuronic acid employed was of the same magnitude as the hexuronic acid content of the protective dose of lemon juice (15 c.c.). It is generally accepted that animals surviving ninety days with no symptoms of scurvy on autopsy and showing normal growth could be kept indefinitely free from scurvy under identical conditions. This allows us to conclude that vitamin C is a single substance and identical with hexuronic acid.

Simultaneously with our previous note, C. G. King and W. A. Waugh<sup>2</sup> reported that they have obtained, from lemon juice, crystals which showed antiscorbutic

activity and were apparently similar in chemical and physical properties to hexuronic acid. The duration of the test period was not stated, and apparently no chemical analysis was made. Until this is done, the nature of their product remains in doubt.

This research was sponsored by the Ella Sachs Plotz Foundation.

J. L. SVIRBELY\*

A. SZENT-GYORGYI

Institute of Medical Chemistry,  
University Szeged, Hungary, April 22

\* Holder of an American-Hungarian Exchange Fellowship, 1931-32, from the Institute of International Education, New York

<sup>1</sup> NATURE, April 16, p. 576

<sup>2</sup> Science, vol. 75, No. 1944, April 1, 1932

EVER since Prof A. Szent-Gyorgyi suggested the possible identity of hexuronic acid<sup>1</sup> with the 'reducing principle' present in all active antiscorbutic solutions, I have been experimenting at various periods in this connexion. These experiments led me to the conclusion that the likelihood of 'hexuronic acid' being identical with the antiscorbutic factor was small, but I much regret that owing to illness I am at the moment precluded from supplying from my experimental notes the relevant data which seem to me to justify this provisional conclusion. Moreover, in view of J. L. Svirbely and Prof A. Szent-Gyorgyi's claims referred to in NATURE of April 16, my previous experimental work on the subject will have to be further amplified, and therefore I cannot now enter into a detailed discussion of the matter. It is my intention, however, to make in this note only one or two comments on Svirbely and Szent-Gyorgyi's results.

According to Svirbely and Szent-Gyorgyi, 1 milligram of hexuronic acid was found to offer a marked protection against scurvy in guinea-pigs, and they justly assert that the activity of this compound is most probably higher, but that, owing to its long exposure to air, a loss of the vitamin has occurred and consequently the minimum dose would be lower than 1 mgm. They further state that 15 c.c. of lemon juice, the minimum protective dose for guinea-pigs against scurvy, is equivalent to 0.5 mgm of hexuronic acid, thus implying that the minimum dose of the antiscorbutic factor is about 0.5 mgm of hexuronic acid. In this connexion it must be pointed out that such minimum doses have been obtained by other workers and myself with fractions from lemon juice which were evidently grossly contaminated. This fact militates rather against the contention that hexuronic acid and the antiscorbutic factor are identical. The interesting point that emerges, in my opinion, from Svirbely and Szent-Gyorgyi's data is that it is possible to prepare active fractions of the antiscorbutic factor from a definite animal tissue.

#### Occurrence of 'Cleistogenes' in certain Grasses

BEDDOWS<sup>1</sup> has raised some interesting points regarding *Triodia decumbens*, particularly as regards the occurrence of 'cleistogenes' at the base of the fertile tillers in the cleistogamous form. Subsequent investigation of their structure has shown that these 'cleistogenes' may contain as many as three florets. Structures are present within their enveloping prophyll which possibly represent empty glumes, these, however, are by no means consistent either as to form or presence. The fertile florets, on the other hand, have well-developed flowering glume and palea. The three

minute bi-sporangiate anthers are intrastigmatic 'Cleistogenes' may ripen as many as two healthy caryopses, which have been found germinating *in situ*.

It is interesting to note that these 'cleistogenes' are apparently somewhat similar to the 'axillary spikelets' described by Weatherwax<sup>2</sup> for *Danthonia sericea*. 'Cleistogenes' have also been found in herbarium material of *Danthonia calycina* and *D. brevibracteata* very kindly supplied by Prof. Friedrich Vierhapper of Vienna.

I have found the rare open flowering or chasmogamous type of *T. decumbens* in Wales. This also produces 'cleistogenes'. Examination of the aerial inflorescences of this form shows a gradation between the characters usually associated with chasmogamy and those usually associated with cleistogamy. Weatherwax<sup>2</sup> describes a rather similar phenomenon in *Danthonia sericea*. ANNIE A. POULTER

### Bacterial Disintegration of the Wool Fibre

WITH reference to the note by R. Waters on the retting of wool,<sup>1</sup> workers in the field of wool research have long been acquainted with the bacterial disintegration of the wool fibre, as mentioned by him.

The phenomenon, as produced by micro-organisms, was described by Schimke in 1892, and, in 1898, Lobner associated such a condition with the activities of bacteria. So far back as 1866, however, Nathusius-Konigsborn directed attention to the spindle-shaped nature of the individual cortical cells. In 1902, Kalmann published illustrations of wool fibres which he had retted by macerating cloth with a pure culture of a spore-forming bacillus.

Confirmatory evidence has since been brought forward by MacInnes (1923), Hirst (1923), Trotman and Sutton (1924), Burgess (1924), Bartsch (1931), and others, most of whom have associated the retting process chiefly, but not exclusively, with members of the aerobic group of the Bacillaceae (Bergey).

As Mr. Waters suggests, the process, or perhaps the enzyme-containing extract, may be used to facilitate the study of the cellular structure of wool. Moreover, provided the cells themselves are not attacked, such a study may *prima facie* help to elucidate the nature of the different constituents of the fibre.

### Biological Effect of Associated Water Molecules

IN a recent book,<sup>1</sup> one of us (H. T. B.) has pointed out that water deprived of trihydrol would be quite useless to living organisms. This suggestion has been supported by experimental results,<sup>2</sup> which demonstrate that water rich in trihydrol obtained from melted ice will sustain filaments of the alga *Spirogyra* in a normal condition for several days, in contrast to filaments maintained under the same external conditions in water from the same source containing a lower proportion of polymerised molecules, in this dihydrol water the protoplasts soon shrink and the filaments become quite limp, due to loss of turgor.

Since the publication of the first report,<sup>2</sup> which described the macroscopical appearance of masses of

*Spirogyra* in the solutions, cytological observations have been made, with the help of Prof. F. E. Lloyd, showing that the water from recently condensed steam, containing less of the active polymer trihydrol, causes the *Spirogyra* filaments to assume a colourless mass which occupies a more compact volume than the same number of filaments in trihydrol water, which maintains the rigidity and turgor of the cells, and in this way the trihydrol filaments occupy a greater volume in the solutions. The collapsed protoplasts in water poor in trihydrol resemble plasmolysis forms with the chloroplasts badly twisted. Similar experiments are now being performed on *Euglena* and *Amoeba*.

### Absolute Energies of the Lines in $\beta$ -Ray Spectra

I HAVE been engaged for some time in investigating the  $\beta$ -ray spectra of thorium-B and the thorium-C bodies, and my measurements suggest that the published values of the energies of the groups may not be so accurately known as is generally supposed. This is a point of considerable importance, since it is now realised that there is a close connexion between the frequencies of the  $\gamma$ -rays which are deduced from  $\beta$ -ray spectra and the energies of the different groups of  $\alpha$ -particles emitted in the actual or neighbouring disintegrations. In investigating this connexion, it is necessary to compare the energies of  $\gamma$ -rays and  $\alpha$ -particles, and since there is no direct method of comparison, it is essential to know the absolute energies of both.

The published values for the energies of the lines in the  $\beta$ -ray spectra of the thorium bodies are nearly all based on a determination of Black's, but this in its turn was based on some experiments I made on the radium-B spectrum nine years ago. So far as my present experiments go, I think it is possible that many of the published values of the energies of the lines in the thorium (B + C) spectrum may be a half per cent or more too high, and quite likely also the values in the radium (B + C) spectrum. I am publishing shortly an account of my measurements, when this point will be fully discussed.

The object of this letter is, first, to direct attention to the need for some other independent measurement of the absolute energies, and, secondly, to prevent the too drastic use of the existing values either in support or criticism of any theory until this matter has been definitely settled.

Cavendish Laboratory,  
Cambridge, April 25

### Passage of Neutrons through Matter. a Correction

IN the note on the above subject published in NATURE of March 26, p. 469, the quantity  $k$  occurring in the formula for the loss of energy per centimetre path of a neutron due to electron collisions, is defined incorrectly as  $2\pi Mv/h$  where  $M$  is the mass of the neutron. This mass  $M$  is not the mass of the neutron, but the reduced mass of the electron and neutron or, effectively, the mass  $m$  of the electron. With this alteration it is believed that the formula is correct.

The field used in the calculation was  $\frac{e^2}{r} e^{-\lambda r}$ , not  $e^2 e^{-\lambda r}$  as there stated, which is of course dimensionally wrong.

H. S. W. MASSEY

Cavendish Laboratory,  
Cambridge, April 22

## Research Items

**Jewish Folklore in Palestine**—Miscellaneous notes on the folklore of the Jews in Palestine recorded by the late Mrs H Spoer (A Goodrich-Freer) and published in *Folklore*, vol 42, pt 1, include references to beliefs connected with sin, disease, and the powers of evil. Many of the Jews of Jerusalem travel down to Jaffa at the coming of the New Year in order to be able to shake their skirts into the waters of the little stream of el-Auja, praying and confessing their sins. It is necessary that there should be fish in the water, in order that they may devour the sins as they are shaken out. A variant of former days, possibly owing to the fact that there was then no railway, was to plant palm-leaf baskets with beans, one for each adult in the family. On the eve of New Year, each would swing the basket over his head, saying, "This basket instead of me", and then drop it in the water. At the present time, the father of the family has to lay his hand on a white cock, confessing his own sins and those of his family, unless they are old enough to perform the ceremony for themselves. During the cholera scare of 1909-10, recently immigrated Russian Jews, who cared nothing for local tradition, averted the danger in their own way by assembling in their own burial-ground on the Mount of Olives and making merry for a day and a night, even celebrating a mock-marriage, to the consternation of the orthodox. In this they were following Russian custom. Russian peasants distract the attention of the spirits of evil by celebrating the marriage of deformed or orphaned persons over the grave of someone who has died of cholera, thus diverting the danger in a direction in which it can do no harm.

**Society Islands' Canoes**—Dr E S Craighill Handy, in the course of a study of houses, canoes, and fishing in the Society Islands (*Bull* 90, Bernice P Bishop Museum, Honolulu), distinguishes three types of craft which have been described indiscriminately as canoes—dug-outs, built-up canoes with round bottom, and composite vessels with sharp keel. All these types depended on the outrigger for stability unless they were double. The dug-out, made for fishing in or near the reefs, sometimes had one or more strips fastened to the upper margin of the hull, thus forming a gunwale, which, giving more freeboard, enabled the canoe-polers to stand on the sides as they propelled the craft. The old built-up canoe consisted of a hollow log, or, in the larger vessels, of several logs fastened together. To these were added side-boards and bow and stern pieces. Their depth seldom exceeded 3 ft and their beam 21 inches. The after-part was generally one-third wider than the fore-part. The bow-piece had fastened to it a board projecting out for four or five feet parallel to the surface of the water. The modern sailing boats of the Leeward Islands are distinctly built-up boats, but they differ from the old model in the shape of the hull, which has a round instead of a V-shaped bottom and perpendicular sides. Both types of craft were made into the great pontoon or double canoes, two being lashed about 4 ft apart by spars and the interval bridged with poles to form a rough deck, sometimes surmounted by a thatched hut. The builders were a guild with rites and places of worship. Men and work were taboo while the canoe was being made, and on its completion a man was sacrificed and eaten by the priest of the chief's temple.

**Twins Reared Apart**—Another pair of identical twins reared apart has been studied by Prof H H Newman (*J Heredity*, vol 23, No 1). These girls,

now twenty-nine years of age, were separated at five months, but both were brought up in the State of Ohio, less than 100 miles apart. Mary, however, has resided in a small town from the age of six years, while Mabel has lived on a farm and engaged in farm work. Mary attended high school, then acted as clerk in a store, and afterwards gave pianoforte lessons. This occupational difference has made Mabel 28 pounds heavier, 1½ in taller, with greater muscular and bone development, although the extreme similarity in finger and sole patterns, eye and hair colour, and features prove them to be identical twins. Several series of psychological and intelligence tests show, however, striking differences in mentality and temperament. Mary ranks much higher in the intelligence tests, which throws some doubt on them as tests of innate ability. This pair of separated identical twins thus differ from each other physically, intellectually, and temperamentally. Of the four similar pairs previously studied, two differed intellectually but not temperamentally, while the other two were intellectually similar but very different temperamentally. In two cases there was also marked physical difference. Averaging these results and comparing them with 50 pairs of identical twins reared together, the difference in intelligence quotient (I Q) of separated identical twins is more than three times as great as that of those reared together. Another conclusion reached is that fraternal twins reared together are, on the average, one and a half times more similar in mental rating than are identical twins reared apart. Dr Newman concludes, nevertheless, that heredity is probably more potent than environment in determining mental status. The study of further pairs of separated twins should throw further light on this problem.

**Further Spread of the Land-Snail *Achatina fulca***—This large East African snail, three inches long, promises to become a menace throughout the tropical and sub-tropical world, half of which it already infests. Y H C Jarrett has prepared an account of its latest naturalisation, in Amoy, a centre from which it may well become a serious pest of Chinese agriculture (*Hong Kong Nat*, vol 2, p 262, 1931). The snail was transported from East Africa to Mauritius nearly a century ago, thirty years later it was carried thence to Calcutta, and in 1910 it had become common in northern Bengal. About 1900 it obtained a footing in Ceylon, and within little more than ten years had become a disgusting pest. From Ceylon or India to Malaya and to Singapore and so to China mark the stages of a progress which is certainly not at an end. The snail is voracious and prolific, it lays about a hundred eggs in its first year, two to three hundred at the end of the second year, and close on a thousand in all. In 1928 it was introduced to Sarawak from Singapore as food for poultry, and by 1930 had become so great a pest that in 1931 a small reward was offered for its destruction—between Oct 1 and Oct 15, 1931, approximately half a million snails and twenty million eggs were destroyed. Hand-picking, dumping in the ocean, burying the animals in sacks deep in the ground have all been tried, without much effect, as methods of control. The last hope appears to be that the snail may find a favoured place in the dietary of the Chinese populace.

**Spotted Wilt of Tomatoes**—One of the most striking results of the work on spotted wilt in tomatoes by Bald and Geoffrey (*Bull* 54, Commonwealth of Australia Coun Sci Ind Res, pp 24, 1931) is the

varied host range of the virus causing the disease *Nasturtium*, *Zinnia*, and Iceland poppy certainly show wide differences for a disease-producing agent which seems to direct its main activities against tomatoes. The tobacco thrip has been confirmed as an insect vector of the disease. *Frankliniella insularis* is shown to be another transmitting insect and to have an intimate relation to the virus. It is necessary that the larva feed on the diseased plant in order that the mature insect produced from it may be viriferous. The virus has been transmitted by mechanical methods, but an extract from a diseased plant loses its disease-producing capacity after standing a few hours. The extract is also rendered inactive by heating to 42° C for ten minutes—a low temperature in comparison with other viruses.

**Oil Origin and Accumulation**—Data of petroleum origin, migration, and accumulation for the oil-pools of the Nemaha granite ridge of Kansas and Oklahoma have been described by Mr J L Rich (*Bull Amer Assoc Pet Geol* for December 1931). These pools are mainly located at a widespread unconformity at the base of the Pennsylvanian shales, where these rest on the edges of Ordovician and Mississippian rocks. The evidence, coupled with that from an analysis of some later structures in the region, indicates that the hitherto assumed contemporaneity of the oil with those shales is suspect, in fact, it was clearly not generated until long after they were laid down, and its source cannot be sought in rocks in the immediate vicinity of the pools as they now occur. It appears possible that much of the oil was generated at a distant source from the present pools as a result of regional metamorphism, during the Appalachian revolution (Pennsylvanian-Permian), of older Palaeozoic rocks, any types capable of yielding petroleum by the mechanism of geodynamic and geothermal 'cracking' of organic mother-substances through the normal agencies of metamorphism would serve. The conclusion that the oil has thus migrated from a great distance is inevitable, possibly from the metamorphosed area in south-east Oklahoma, and if the Appalachian revolution was responsible, then we may fix generation, migration, and accumulation at this epoch with reasonable certainty. A sharply contrasted theory with those previously held, and a decided hint in other cases where contemporary deposition of oil from indigenous organic matter subject to biochemical change—a common postulate—is invoked.

**Forecasting of Indian Monsoon Rainfall**—In vol 4, No 37, of the *Scientific Notes of the India Meteorological Department*, S R Savur discusses the various formulæ used in seasonal forecasting in the India Meteorological Department since Sir Gilbert Walker placed the subject on its present mathematical basis in 1924. These formulæ connect future Indian rainfall with various meteorological data relating to different parts of the world that are available at the time that the forecast is made. A good deal of work has been done, especially by Fisher, since these formulæ were worked out, with the object of deciding with what degree of confidence multiple correlation coefficients of the kind used by Walker can be regarded as 'significant'. Use is made of this recent work in deciding which, if any, of Walker's factors are likely in the long run to be found insignificant, and which may therefore be discarded. The 1924 formulæ stand this critical examination on the whole very well, but certain factors have been found to be less important than was formerly supposed to be the case, and it is evidently the intention of the writer of this paper to try to find other factors that could replace those rejected. Thus, it appears, is likely to be a

difficult task, until it has been accomplished, the accuracy of the forecasting will remain at its present level, seeing that a mere reduction in the number of factors used cannot bring about any improvement. Such is the economic importance of the monsoon rains that the moderate measure of success already attained cannot be dismissed as of no practical value.

**Vibrations of a Lofty Building**—Mr T Fukutomi made some useful observations on April 25–May 25, 1931, on the vibrations of the Takeda Building in Tokyo (*Earthq Res Inst Bull*, vol 9, 1931, pp 485–507). This consists of an underground floor and nine other floors, and its total height is 99 ft. Tromometers of the same type were placed on the underground, fourth, and ninth floors, the intermediate one being removed to the sixth floor on May 16. As a rule, the building vibrated with a period of 0.4 sec, the amplitudes of the vibrations on the ninth, sixth, fourth, and underground floors being in the ratios 1.00 : 0.84 : 0.67 : 0.06. There is a diurnal period in the amplitude with its maximum epoch at 3 or 4 P.M., possibly due to the passage of tram-cars. During the month of observation, four sensible earthquakes were recorded, the mean maximum accelerations on the floors being as 1.00 : 0.42 : 0.26 : 0.24. On the underground floor, the direction of motion was nearly perpendicular to the line joining the origin and the building, on the ninth floor, it coincided very nearly with the direction of free vibration.

**Ultra-sonic Waves in Liquid Columns**—Vol 6 of the *Canadian Journal of Research* contains two papers from the National Research Laboratory, Ottawa, contributed by Drs R W Boyle, G S Field, and D K Froman, on dispersion and selective absorption in the propagation of ultra-sonic waves in liquids contained in tubes. The liquids were water, naphtha, castor oil, transformer oil, and chloroform, the tubes of glass, celluloid and cellophane of various thicknesses, and the oscillations were produced by the action of a high frequency electric circuit on a quartz or tourmaline piezo-electric oscillator. The frequencies were from 20 to 100 kilocycles per second and were measured by means of a Hertzian wave meter, and the velocity of phase propagation along the column by the distances apart of the nodes, which are indicated by the small bubbles which collect there. The authors find that the velocity varies with the frequency in the same way as the velocity of light varies on the two sides of an absorption band, and that the absorption is due to the conversion of the energy of longitudinal into that of transverse oscillations, the frequency of which is determined by the diameter of the liquid column, and for thin tubes is independent of the material and thickness of the walls of the tube.

**$e/m$  from the Zeeman Effect**—The accepted spectroscopic value for the ratio of the charge of an electron to its mass has been substantially confirmed in an investigation of the Zeeman effect of zinc  $\lambda 6362$  and cadmium  $\lambda 6439$  by J S Campbell and W V Houston (*Phys Rev*, Feb 15). This is of special interest, since recent values for the ratio obtained from cathode rays agree with those found from optical experiments, and the present measurements are made by a method very different from the earlier in detail. The splitting of the lines was produced by the field in an air-core solenoid consuming about 50 kilowatts, and was determined with a Fabry-Perot interferometer, yielding the result that  $e/m$  is  $1.7579 \pm 0.0025 \times 10^7$  e.m.u. per gram.

**Rates of Solution of Gas in a Liquid**—The commonly accepted theory of the rate of solution of a gas in a

liquid, due to Noyes and Whitney, assumes that a stationary film exists on the surface of the liquid and instantaneous saturation of the upper layer of this by the gas. The rate of solution then depends on the rate of diffusion of dissolved gas. Miyamoto (*Bull. Chem. Soc. Japan*, Jan.) points out that the thickness of the stationary film resulting from this theory,  $10^{-3}$ – $10^{-2}$  cm, is improbable, and he has examined the result of an assumption that among the molecules of colliding gas only those with component velocities normal to the surface greater than a threshold value can enter, and a similar relation holds for molecules escaping from the liquid. No assumption of a stationary film is made, which seems the correct procedure in the case of well-stirred liquids. It is shown that the new theory leads to an equation of the same form as the old one and in addition explains the results of experiments on the rate of oxidation of sodium sulphite solutions, stannous hydroxide, and ferrous hydroxide, previously made by the author, in a more satisfactory manner. The maximum rates of oxidation in all these cases are identical under the same conditions, and are governed by the maximum rate of solution of oxygen in water. The value of the threshold velocity of the entering oxygen molecules is calculated as 3.4 times the root mean square value at  $15^{\circ}$ – $35^{\circ}$ .

**Facsimile Radio Transmission**—Science advances with the ability to make measurements. During the last few years, mainly owing to the advent of short-wave transmissions with wave-lengths ranging between 14 metres and 50 metres, greatly improved methods of measurement have been introduced, and a new technique of echo and facsimile measurement has been developed. In 'facsimile' measurements, the

object is to record at the receiving end a pulse emitted at the transmitting end. In practice, the message is placed on a drum and a spot of light from a rotating optical system is caused to scan the message. The reflected light from the picture is led to a photo-cell. The output of the photo-cell modulates the transmitter. A similar optical system revolving in synchronism at the receiving end records the signals. In a paper on radio transmission, read to the Institution of Electrical Engineers on March 23, T. L. Eckersley utilises some of the phenomena observed in facsimile transmission to obtain information about the Kennelly-Heaviside layer. Facsimile records usually show a series of one, two, three, or more separate marks corresponding to the arrival by different paths of a single transmitted impulse. The differences in the times of arrival can be measured with high accuracy. It is from these measured time differences that the author finds the ray angles, heights of the effective layers, and the maximum electronic density in the Kennelly-Heaviside layer. For high angle transmission, for example, those recorded between Writtle near Chelmsford, and Somerton, in Somerset, the marks (echoes) are so regular that they can be definitely fitted into a multiple-reflection scheme. For shallow angle transmission the echo times are more irregular, and difficulty is experienced in fitting them into an optical scheme. Mr Eckersley calls a ray which has been reflected  $n$  times from the K H layer the  $n$ th order ray. A study of facsimile transmission from South Africa to Montreal shows that the high angle rays have greater attenuation than the lower ones. This suggests that at sufficient distances, only the lowest angle ray will survive, and perfect facsimile reproduction will result.

### Astronomical Topics

**New Comet**—Mr Carrasco, of the Madrid Observatory, discovered a comet of the twelfth magnitude on April 22. Several observations have been obtained, from which Miss Vinter Hansen and Mr Moller, both of the Copenhagen Observatory, have deduced the following elements:

|          |                        |
|----------|------------------------|
| T        | 1931 Dec 14 594 U T    |
| $\omega$ | $117^{\circ} 25' 07''$ |
| $\Omega$ | $17^{\circ} 43' 53''$  |
| $i$      | $58^{\circ} 11' 09''$  |
| $\log q$ | 0.394164               |

Thus the comet passed perihelion 4 months before discovery, and is now 3 units from the sun and 2 units from the earth. Dr W. H. Steavenson obtained the following observation at Norwood:

May 1d 0h 33 0m, R A  $12^{\text{h}} 6^{\text{m}} 40.98^{\text{s}}$ , N Dec  $22^{\circ} 1' 34.8''$  (1932 0)

This is very close to the ephemeris from the above orbit, which is continued below (for 0<sup>h</sup>):

|       | R A                                       | N Dec            |
|-------|-------------------------------------------|------------------|
| May 5 | $12^{\text{h}} 3^{\text{m}} 0^{\text{s}}$ | $20^{\circ} 41'$ |
| 9     | $11^{\text{h}} 59^{\text{m}}$             | $19^{\circ} 21'$ |
| 13    | $11^{\text{h}} 57^{\text{m}}$             | $18^{\circ} 1'$  |
| 17    | $11^{\text{h}} 55^{\text{m}}$             | $16^{\circ} 42'$ |

Dr Steavenson also obtained an observation of the comet Houghton-Ensor (so named because Mr G. E. Ensor discovered it independently at Pretoria on April 2)

April 30d 0h 17 2m, R A  $12^{\text{h}} 42^{\text{m}} 50.38^{\text{s}}$ , S Decl  $17^{\circ} 18' 43''$  (1932 0)

Dr Waterfield observed it at Headley on the same night, and considered that its magnitude was eighth or ninth, it was a fairly large object, with some central condensation. It is keeping very close to the

ephemeris of Cunningham and Whipple, which is as follows (for 0<sup>h</sup>):

|       | R A                                         | Decl              |
|-------|---------------------------------------------|-------------------|
| May 5 | $12^{\text{h}} 42^{\text{m}} 19^{\text{s}}$ | $S 8^{\circ} 3'$  |
| 9     | $12^{\text{h}} 42^{\text{m}} 30^{\text{s}}$ | $S 2^{\circ} 2'$  |
| 13    | $12^{\text{h}} 43^{\text{m}} 13^{\text{s}}$ | $N 2^{\circ} 51'$ |
| 17    | $12^{\text{h}} 44^{\text{m}} 25^{\text{s}}$ | $N 6^{\circ} 47'$ |

U. A. I. Circ 370 reports another remarkable object discovered by Dr Reinmuth at Königstuhl:

April 27d  $22^{\text{h}} 13^{\text{m}} 5^{\text{s}}$  U.T., R A  $13^{\text{h}} 42^{\text{m}} 7.8^{\text{s}}$ , S Decl  $10^{\circ} 41' 52''$  (1932 0), mag 12.5, Daily motion  $-4^{\text{m}} 56^{\text{s}}$ , S.  $4'$ , the retrograde motion in R A is greater than that of any of the known asteroids, so either it is a comet or an asteroid with a very abnormal orbit.

**Astronomical Photographs at Harvard**—The immense value of the great collection of astronomical photographs taken at Harvard Observatory is known to all astronomers. On many occasions it has enabled the history of novæ or variables to be traced for years before their discovery. Early images of Eros were also found upon them. Science Service announces in a bulletin dated March 23, that this valuable collection has now been placed in a new fireproof building at Harvard, where the plates are both safer and more easily accessible. It will be news to many that some plates of the collection go back to the year 1850, when the first photograph of a star ever taken was made at Harvard with the 15-inch equatorial. But it is only from the introduction of the dry plate in the early 'eighties that the series becomes continuous. The inauguration of the new building comes at an appropriate time, as Harvard is the appointed meeting place of the International Astronomical Union at the beginning of September.

## Research in Rubber Manufacture

THE twelfth annual report of the Research Association of the British Rubber Manufacturers, presented at the annual meeting of the Association on Feb 2, gives not only a succinct account of its varied activities but also a striking picture of the extent to which scientific research is serving the intellectual, technical, and material development of the rubber industry. Since the commencement of its career, the Association has contributed more than sixty papers to the scientific and technical Press, while nearly 25 per cent of the published matter in the *Transactions* of the Institution of the Rubber Industry from manufacturing sources originates from the Croydon laboratories. Apart from this, many confidential reports and circulars have been issued to members, and the scientific investigations carried out range from plasticity measurements on raw rubber, the comparison of Para, smoked sheet, and crepe, the properties of synthetic rubber or compounding ingredients such as litharge, accelerators and antioxidants, on the properties and testing of vulcanised rubber, to the numerous applications of vulcanised and hard rubber in tyres, cables and insulation materials, footwear, flooring, and proofings.

Joint investigations on cable insulation rubber have been carried out with the Admiralty, and on hard rubber and on a series of butadiene polymerisation products made by the I G Farbenindustrie A-G intended for use as insulation materials, with the British Electrical and Allied Industries Research Association. Testing apparatus has been devised which has simplified works' laboratory technique, and the cumulative value of the Association to the public, apart from the industry, is illustrated by the increased mileage of motor tyres, which as a result of research has increased from 2000 miles service in 1900 to 12,000, with an estimated car-mile saving of at least 4d, or an approximate saving to the public of £100,000,000 on tyres of 1900 quality. An increase of 1.2 per cent in the life of boots, shoes, hot-water-bottles, etc., due to the use of antioxidants would represent a saving to the public far greater than the amount payable to the Research Association under the levy scheme.

In view of these results, it is somewhat disappointing to find that finance is still causing the Association a good deal of anxiety. In part this is due to the increased responsibilities thrown on the Association by the advance of scientific knowledge, and to the growing use of its services by members and subscribers, but the adverse and uncertain general economic conditions of trade have been a further factor. In addition, the reduction of the grant from the Department of Scientific and Industrial Research from £2500 to £2000 for 1932 as a measure of national economy has placed on the industry itself the onus of finding resources for any expansion in the scientific services provided by the Association. It is accordingly the more unfortunate that, although passing its second reading, the Rubber Industry Bill made no further progress, owing to the congestion of Parliamentary business, and the expansion which the institution of the levy would make possible is still deferred.

Apart from its strictly scientific work, the Association participated in the successful negotiations between a committee representative of chemical interests generally and the British Engineering Standards Association which resulted in the formation of the British Standards Institution, covering the whole industrial field. The negotiations issued in a scheme providing for an organisation divided into four main

divisions dealing with building, engineering, chemical, and textile interests, the proposals thus representing the fulfilment of one of the recommendations of the Imperial Conference dealing with co-ordination of standardisation within the Empire. On the Chemical Division Council the interests of the rubber industry are represented by the India-Rubber Manufacturers' Association, but the matter of standardisation is one of prime importance to the Research Association and, during the year, preliminary consideration has been given to the internal organisation of the rubber industry for the formulation of specifications for manufactured rubber goods, and the Association has co-operated during 1931 in the preparation or revision of British standard specifications for moulded insulating material for general electrical purposes, rubber tubing for use with petrol, benzol, and paraffin, oil-resisting rubber tubing, rubber-jointing material, benzol and rubber belting.

Since there are no rubber organisations in the Dominions in any way analogous to the Research Association, apart from those in Ceylon and Malaya, the question of Imperial co-ordination in research scarcely arises in the rubber industry, but visits from representatives of the National Research Council of Canada and the Australian Council for Scientific and Industrial Research already afford a basis for some effective liaison when the systematic study of the problems of rubber manufacture is taken up in the Dominion or the Commonwealth. Close relations have been maintained between the Research Association and the Rubber Institute of Malaya, and a number of technical questions, such as the suitability of air-dried sheet for manufacturing purposes, the concentration and extraction of latex serum in bulk, latex emulsification problems, have been discussed between the two organisations. In addition, although with the imposition of a small cess upon rubber exports for the maintenance of the Ceylon rubber scheme, financial responsibility passed from London to Ceylon, by joint arrangement between the organisations in Ceylon and Malaya a scheme has been evolved for transfer of control to a Joint Advisory Council, thus securing continuance of the scientific investigations of the properties of the raw material and close co-operation between the producer and the manufacturer.

Co-operation with the Rubber Growers' Association has also been established, not only in publicity work on behalf of the industry, but also in the investigation of difficulties holding up the utilisation of rubber for various purposes, and the study of promising potential applications. Among such problems may be mentioned the utilisation of latex-oil emulsions as lubricants, the acoustic properties of rubber flooring for cinemas, the increasing of the resistance of rubber to oils, while such questions as the destruction of rubber by white ants, rubber goods for tropical railways, resistance of coloured rubber paving to light and weather, have been the subject of joint discussion. Co-operation in the study of problems confronting the utilisation of rubber has, however, by no means been confined to the Rubber Growers' Association. Investigations on ebonite have been carried on jointly with the British Electrical and Allied Industries Research Association, in which the Ceylon rubber research scheme and representatives of Government departments have participated. The War Office, India Office, Air Ministry, and Post Office are all represented on the Association's Tyre Research Committee, and co-operation with the motor industry and the British

Boot and Shoe and Allied Trades Research Association on problems relating to the manufacture and utilisation of rubber will undoubtedly develop

An important feature of the work of the Association is its library and information bureau, which serve the growing needs of all connected with the industry for a source of information and advice over a wide range of subjects. Without the regular issue of the monthly summary of current literature it would be difficult for the industry to keep itself abreast of all the latest developments, and when to this invaluable intelligence service there is added the issue of periodical circulars summarising the available knowledge on many scientific, technical, and economic subjects and the satisfying of an ever-growing number of inquiries (amounting to 690 in 1931 alone) covering all phases of the rubber industry, it can safely be asserted that the Research Association is rendering to the British industry services that are unsurpassed by the similar associations in Germany and Holland. In addition, a centralised organisation is able to carry out work of this kind much more thoroughly and efficiently than any one firm alone could hope to do, and avoids all the overlapping and duplication of effort which would occur if individual firms maintained their own organisations.

Already the number of cards in the index maintained by the Association amounts to well over 125,000, and the subject cards alone are increasing by about 14,000 a year. These statistics, however, give little idea of the magnitude of the work involved in cross indexing, and in the course of the work the library and information bureau has evolved its own system of classifying scientific, technical, and commercial information on rubber, based on a generalised decimal notation, although the International Brussels system was rejected on account of serious difficulties it offers in use for rubber information. The value of the work

of this section of the Association is further attested by the recognition of the library in 1930 by the Carnegie Trust as an outlier of the National Central Library. The generous grant made in accordance with that recognition has made it possible to expand considerably the library collection, and thus to improve further the utility of what is already a fully representative collection of all modern publications and particularly in regard to trade literature.

The above brief outline of the activities of the Association taken from the annual report gives some indication of the many services which the Research Association is rendering to the rubber industry, and illustrates the way in which that research reacts to the direct benefit of the public, as well as the tendency towards co-operative research between different branches of industry. One of the most surprising things in the report is the smallness of the staff with which this extensive and important work is being carried out. When we consider that as yet relatively little is known regarding the nature of rubber or the changes which occur during vulcanisation, apart altogether from the many problems presented by the utilisation of rubber, it is clear that the expansion in the work of the Association, and particularly the extension of systematic fundamental research which is anticipated as a result of the Rubber Industry Bill passing into law, should be of the utmost value and importance to the industry. Its practice cannot but be imperfect when the mechanism of the essential process is incompletely understood. The future of the rubber industry depends upon the wise, continuous, and adequate prosecution and application of scientific research, and the praiseworthy work already carried out by the Research Association indicates the possibilities when the industry as a whole devotes to the support of co-operative research the energy and financial support which it imperatively demands.

### Uses of Empire Timbers\*

UNDER the auspices of the Forest Products Research Board of the Department of Scientific and Industrial Research, inquiries are being carried out into the possible uses of Empire timbers. The results of the first year's investigations are given in the annual Report of the Board before us. Under the auspices of the Empire Timber Committee the work was started late in 1929, further facilities for the contemplated research becoming available by the end of last year.

Tests have been undertaken with East African camphor wood from Kenya for cabinet making, walnut and sapeli woods from Nigeria, both for cabinet making, and *Meranti tombaga* and Keruing timbers from the Federated Malay States, which might displace some of the Philippine timbers on the London market, provided they can be imported at competitive prices. New Zealand silver beech is to be tested for furniture wood at High Wycombe and in the making of rifle stocks at the Small Arms Factory at Enfield. Another subject reported upon is the investigations into the creosoting of British Columbian Douglas fir, since this timber might prove a considerable asset for railway sleepers. So far, Douglas fir timber has proved less easy to creosote than Baltic fir. By adopting the Canadian and American method of what is known as 'incising' over the sleepers, it was found possible to inject as

much creosote into them as the Baltic species will absorb.

The writers of the report comment upon the increased interest of the public in Empire timbers, for use in both Government and private buildings. But the opinion is stressed that the joint work of the Department and the Empire Marketing Board is not by itself sufficient to cover the necessities of achieving a general development and national use of Empire timbers. Unless production and marketing are closely co-ordinated with research, the work of the Board will be impaired. Apart from measures to be taken by the timber trade, it is stated that there is a lack of adequate official machinery for dealing with difficulties in the producing areas, more especially in certain of the tropical regions.

The difficulties, it is urged, could be largely overcome by comprehensive botanical and economic surveys of our forest resources, involving some enlargement of the facilities at the disposal of the Imperial Forestry Institute and the forest services, and by closer liaison and personal touch with the interests concerned in the country of origin. The suggestion of the enlargement of the facilities at the disposal of the forest services is timely at a moment when most of these services are being cut down owing to financial stringency.

The efforts of the departments responsible for the admirable work described in the report here dealt with require the careful consideration of the authorities responsible for forest administration in the various Colonies.

## University and Educational Intelligence

CAMBRIDGE—It is proposed to confer the degree of *ScD honoris causa* upon Sir William Bragg, director of the Royal Institution of Great Britain.

A lecture on the Liversidge Foundation will be delivered by Prof A V Hill, Foulerton Research Professor of the Royal Society, on Friday, May 13, at 5 P M, on "Chemical Wave Transmission in Nerve".

EDINBURGH—Sir Thomas Hudson Beare, professor of engineering, has been granted leave of absence, having been appointed leader of the official delegation from Great Britain to the Congress of the International Association for Bridge and Structural Engineering, to be held in Paris on May 19-25.

The Scottish Universities' Committee of the Privy Council has approved of a scheme for the affiliation to the University of the Heriot-Watt College. An ordinance is to be prepared in conformity with the provisions of the Universities (Scotland) Act, 1889, giving effect to the scheme.

Dr George W M'Crea, assistant in the Department of Chemistry, is exchanging for one year from Oct 1, 1932, with Prof Warren C Vosburgh, of Duke University, Durham, North Carolina, U S A.

MANCHESTER—Applications are invited for the Grisedale biological scholarship (botany or zoology, preferably the latter), value £200. The scholarship is offered to graduates who have already had some training in research. The latest date for the receipt of applications is June 1. They should be sent to the Registrar of the University.

THE London County Council is again offering two Robert Blair fellowships in applied science and technology, each of the value of £450 and each tenable for a year. The scholarships are for advanced study, and will be tenable in the dominions, the U S A, or abroad. Particulars and application forms are obtainable from the Education Officer (T 3), County Hall, S E 1. Completed forms must be returned by June 1.

THE twenty-third Conference of the Association of Teachers in Technical Institutions is to be held at Cardiff on May 14-17. The first public meeting will be on Whit Monday, when the Conference will be officially welcomed by the Lord Mayor of Cardiff, and the retiring president, Mr H Ade Clark, will induct the president for 1932-33, Mr S H Moorfield, Wigan and District Mining and Technical College. Among the topics to be discussed by the Conference are the relation of education and industry, junior instruction centres, junior technical schools, and recruitment for industry. An exhibition of books and apparatus will be held in the Technical College during the Conference.

## Calendar of Geographical Exploration

May 8, 1922—The Alps of Chinese Tibet

Prof J W Gregory, accompanied by C J Gregory, left Bhamo on the Upper Irrawaddy and went to Tengueh, covering 145 miles in 8 days. Thence they crossed the Salween and went to Yungchang, afterwards exploring a region completely unknown from the geological point of view, and very little known geographically. They reached the valley of the Yangtse Kiang after ascending the Loma Ho and discovering a series of hot springs. In 1893, Prof Gregory examined the East African Rift valley northward from Lake Naivasha to Lake Baringo, he is now on an expedition in the Andes.

No 3262, Vol 129]

May 9, 1926—To the Poles by Aeroplane

Commander R E Byrd, with F Bennett, made the pioneer aeroplane flight to the north pole and back, from Spitsbergen. In 1928-29, from a base near the Bay of Whales, Byrd examined Marie Byrd Land, and also flew to the south pole and back.

May 10, 1553—Willoughby and Chancellor

Sir Hugh Willoughby, in the *Bona Esperanza*, accompanied by two other vessels, left Ratchliffe on a voyage which was intended to open a northern route to India. The equipment of the vessels was carried out under the direction of Sebastian Cabot, then an old man. On July 14 they landed on the Norwegian coast, in that region from which Othere had begun his voyage to the White Sea in the time of Alfred the Great. Two of the vessels reached the coast of Russian Lapland and found a good harbour at the mouth of the Arzina River, probably the modern Varzina, but during the winter Willoughby and all his men died, probably of scurvy. Russian fishermen found the two vessels and the corpses in the following year. Willoughby's will showed that he was alive in January 1554. The third vessel, the *Edward Bonaventura*, commanded by Chancellor, was separated from its two companions by a storm in August 1553, and reached the mouth of the Northern Dwina in the White Sea, where a small monastery existed and where the port of Archangel later developed as a result of Chancellor's voyage. Chancellor and his companions were invited to Moscow, and the route from England to Russia via Archangel was established shortly afterwards. The expedition thus had very different results from those expected by its promoters. Chancellor was wrecked near Aberdeen in November 1556, when conveying a Russian embassy and a cargo of goods from the Dwina River. He and his wife and seven Russians were drowned.

May 12, 1539—Discovery of the Mississippi

Hernando de Soto started from Havana, and landed in Espiritu Santo Bay, on the west coast of the present State of Florida, in search of the gold reported by Gabez de Vaca. He probably passed into Georgia as far as 35° N, then south to the region where Mobile now stands, and finally north-west to the Mississippi, which he reached in 1541. He wintered on the Ouachita, in what is now Arkansas and Louisiana, west of the Mississippi. On the return journey along the Mississippi, de Soto died in 1542, but his men, under Luis Moscoso de Alvarado, descended the river to the sea from a point near its junction with the Arkansas, the voyage occupying 19 days. Thence they coasted along the Gulf of Mexico to Panuco. This important journey was the first extensive exploration of the southern United States, it resulted in the discovery of the Mississippi, and gave to the world the first account of the social customs of the Indians of the southern States.

May 12, 1721—Greenland

A Norwegian missionary, Hans Egede, with his wife and family, sailed from Denmark, and landed on the west coast of Greenland near Godthaab. He lived there until 1736, and collected much information about the south-western districts and the Eskimo tribes. Greenland had been known to the Norse, Eric the Red having sailed there in 982 and spent three years in its south-western regions. The Norse colonies there flourished at first but died out in the fifteenth century, J Davis finding no trace of them in 1585. Egede's settlement led to renewed exploration and colonisation of the interior.

## Societies and Academies

## LONDON

Royal Meteorological Society, April 20—J N L Baker The climate of England in the seventeenth century Descriptive writings provide evidence of a somewhat inconclusive character, and this can be supplemented by the reports of the Venetian Ambassadors, published in the Calendars of Domestic State Papers (Venetian) and elsewhere The Calendars of Domestic State Papers furnish many scattered references, both to short periods and to long spells of weather, and from these a continuous account can sometimes be constructed They also include important tables of winds covering the periods 1667–72 and 1675–78 The MS diaries preserved in the Bodleian Library are also of value That of Dr Napier covers the period 1598–1635 but is very fragmentary that of Elias Ashmole only extends from 1677 to 1685 but is unusually full Most of this evidence has not previously been used, and an attempt has been made to correlate it with the accepted rainfall figures of Townley and Derham and other records, such as the diaries of Evelyn and Pepys In a number of cases the older evidence is unreliable, at the same time, all the evidence is of an unscientific nature, and strict comparison with reliable evidence of modern times is apt to lead to erroneous conclusions—C W G Daking The meteorology of Kamaran Island (Red Sea) The upper winds of this region would have played a big part in the journeys of the air-ship *R 101* to India and back, and it was probably because this information would have been so valuable that observations were commenced at Kamaran Island In most respects, the climate experienced is typically tropical, but it is noteworthy that, for so small an island, the conditions are as trying as those experienced inland on the continents of Africa and Asia—David Brunt Notes on radiation in the atmosphere (1) The absorption spectra of water vapour and liquid water are applied to consider the justification for regarding cloud sheets and fog as black body radiators Long wave radiation from the atmosphere fits very closely a formula only involving the absolute temperature and the vapour pressure The fall of temperature after sunset on clear nights is closely proportional to the square root of the time from sunset The tendency to instability is greatest for clouds of medium height

Geological Society, March 9—W G Tidmarsh The Permian lavas of Devon With the exception of certain members in the south of the area, these are intermediate rocks, ranging from types resembling basalts to normal and olivine minettes Details of various lavas and analyses of fourteen rocks and three minerals are presented—B Jones The geology of the Farbourne-Liwyngwil district, Merioneth The area is occupied by a westward extension of the Upper Cambrian and of the Ordovician rocks of the Arthog-Dolgelley and Cadei Idris districts, and the sequence is, in general, similar to that in those districts, with, however, certain noteworthy differences An unexpected discovery was that of a wide expanse of Bala beds extending along the Dysynni valley and north of the Tallylyn (Bala) fault

## PARIS

Academy of Sciences, March 21—H Deslandres Simple relations between the molecular spectrum and the structure of the molecule From a study of the infra-red spectra of binary molecules the author has deduced the formula  $\nu = 1062 \cdot 5 q'/r's'$ , where  $\nu$  is the frequency,  $s'$  the number of external electrons excited

in one of the atoms,  $q'$  and  $r'$  being integers The possible meaning of this formula is discussed and some further applications given—M de Broglie, F Dupré la Tour, L Léprince-Ringuet, and J Thibaud The effects of ionisation observed in the presence of the beryllium rays under the excitation of the  $\alpha$ -rays from a bulb containing radium emanation—C Matignon, Kling, and Florentin The transformation of saturated acyclic hydrocarbons into ethylenic hydrocarbons Details of the products obtained by the action of catalysts upon ethane, propane, and butane at temperatures ranging from 500° to 650° C The catalysts used were copper and nickel, both on pumice—André Blondel The cyclic impedances of an earthed polyphase cable—C Camichel, L Escande, and G Sabathe The similitude of vortices—Emile Guyenot, Miles K Ponce and J Wietrzykowska The luteinisation of the ovary and masculinisation in the guinea-pig—Jean J Placinteanu The deduction of Maxwell's equations with the aid of Eddington's wave tensor—C E Winn The oscillation of the means of Holder and of Cesàro—Georges Bouligand Some points of the theory of ensembles—Louis de Broglie The densities of mean values in Dirac's theory—Nicolas Kryloff and Nicolas Bogoliuboff The phenomenon of the establishment of the silent zone (*entraînement*) in radio technique—J F Cellierier The phonic test for the measurement of the mechanical intensities of sounds—François Boissier A new iodine accumulator This battery is based on the reversible reaction  $ZnI_2 = Zn + 2I$  Its e m f is 1.2 volts and efficiency about 80 per cent—Pierre Jolibois and Georges Fourrier The photographic registration of pH during reactions in solution The apparatus described in a previous note for recording the electrical conductivity of an electrolyte as a function of the quantity of reagent added has been modified to give a record of the pH of a solution A reproduction of the curve obtained by the neutralisation of orthophosphoric acid by soda is given—H Colin and Mlle A Chaudun The action of neutral salts on the inversion of sugar by acids—René Dubrisay A phenomenon of capillary chemistry A solution containing a mixture of sodium laurate and oleate is made to foam by passing a current of air or nitrogen Analysis of the froth and residual liquid confirmed the theoretical view that the ratio oleic acid to lauric acid was higher in the froth than in the residual solution—Ed Chauvenet and J Tonnet The anhydrous combinations of thoryl chloride with the alkaline chlorides—L Bert and E Andor The bromination of  $C_6H_5 \cdot O \cdot CH_2 \cdot CH \cdot CHCl$ —R Cornubert and P Robinet The phenomena of isomerism in the tetrahydropyrones—M Grunfeld The relation between the ultra-violet absorption spectra and the reaction velocities for certain classes of amines—Marius Badoche Researches on the coloured hydrocarbons a blue hydrocarbon—L Royer The orientation of crystals of the epsomite series by mica—Mlle Lucienne George The origin of the Gnetaleæ—D Montet The effect of radioactivity on the germination of bulbs—H Hérissé and J Laforest A heteroside extracted from the Portuguese laurel, *Cerasus lusitanica*—Philippe Fabre The utilisation of electromotive forces of induction for the registration of the variations of velocity of conducting liquids a new hamodromograph without a paddle in the blood The apparatus is based on the e m f due to induction developed in any moving conductor in rapid motion in an intense magnetic field—H Simonnet and G Tanret Some physiological properties of nerine and other proximate principles of the oleander The glucosides of the oleander are cardiac glucosides—A Machebœuf and G Sandor Study of the extraction of the lipides of blood serum by ether in presence of

alcohol The ratio of ether to alcohol for maximum extraction must fall between narrow limits the time of contact is also important —Jean Roche The action of oxygenation on certain physico-chemical properties of the hæmocyamine of the snail —C Mathis and C Durieux The identity, at Dakar, of *Spirochaeta Duttoni* var *crocodyræ* and the spirochaete naturally infecting *Ornithodoros erraticus*

## VIENNA

Academy of Sciences, Jan 14 —Leopold Schmid and Walther Rumpel Constitution of the colouring matter in toad-flax flowers (*Linaria vulgaris*) It was found earlier that this colouring matter contains a molecule  $C_{17}H_{14}O_6$  united to form a glucoside with one molecule of a hexose and one of a methylpentose It is now shown that the coloured constituent is the 4,6-dimethyl ether of scutellarein The flowers contain also entricontane and mannitol —Julius Donau A new micro-gravimetric analytical process A combined precipitating and filtering dish with a platinum-foil cover and with platinum black as filtering layer, is described Dissolution, precipitation, washing, and drying are carried out in the same vessel and losses of precipitate thus entirely avoided Accurate results have been obtained in the determination of chlorine, iron, sulphate, and potassium chloride —Robert Janoschek Geology of the Brenner Hills —Karl Linsbauer Nuclei, nucleoli, and movements of the plasma in the vesicular cells of *Mesembryanthemum cristallinum* —Gustav Jantsch and Ernst Wiesenberg Higher valency compounds of the rare earths (1) Lanthanum oxide —Martin Gusinde and Viktor Lebzelter Somatology of the Indians of Tierra del Fuego Sixty years ago the three different aboriginal races of Tierra del Fuego numbered together about 12,000 members, but it is estimated that less than 300 of pure descent now remain The region peopled by each of these races is sharply defined and little mixing occurs Their modes of life vary, the Yamana and Halakwalup being water-nomads and the Selk'nam hunter-nomads The results of anthropological measurements of a number of individuals of each tribe are given —Otto Sickenberg A new antelope, *Parurhætherium rugosifrons*, 107 gen nov spec, from the Lower Pliocene of Samos

Jan 21.—Contributions to the knowledge of the climate of towns (1) Hanns Tollner Distribution of temperature in Vienna in the summer of 1931 —(2) Friedrich Lauscher and Ferdinand Steinhauser Radiation in Vienna and its neighbourhood —Fritz Vessely and Editha Nadler Substances contained in the root of *Pimpinella saxifraga* (2) In addition to pimpinellin and isopimpinellin, previously described, this root contains also a third compound of the same class, namely, isobergaptene, to the molecule of which a three-ringed structure is ascribed —Fritz Vessely and Ferdinand Kallab A re-arrangement in the flavone series —Leopold Schmid and Anton Seefeldt The colouring matter of the yellow dahlia This colouring matter comprises, besides apigenin, also a deep yellow compound,  $C_{15}H_{10}O_6$ , which melts at  $324^\circ$  and contains three hydroxyl groups and a -hydroxybenzoic acid residue in its molecule —Karl Jorsch Action of ammonia and amines on esters of unsaturated acids (1) Action of ammonia, methylamine, and diethylamine on ethyl crotonate —Franz Uhrmann Biochemistry of the luminous bacteria (1) Influence of sodium and potassium chlorides and bromides —Karl Strubecker Rhombic nets of straight lines and circles —Alfred Tarski Concept of truth in the language of the deductive sciences

## Forthcoming Events

## FRIDAY, MAY 6

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers), at 10 A M —Annual Meeting  
ROYAL SOCIETY OF MEDICINE (Otolaryngology Section) (Annual General Meeting), at 10 30 A M —Discussion on Labyrinthitis  
CAMBRIDGE UNIVERSITY (in Senate House), at noon —Prof A Einstein Die Theorie der Elektrizität im Rahmen der allgemeinen Relativitätstheorie (Rouse Ball Lecture)  
INSTITUTION OF MECHANICAL ENGINEERS (London Spring Meeting), at 2 30 —A Binns Recent Developments in the Mechanical Equipment of the Port of London Authority —At 7 30 —J H Boyd The Building of a Modern Motor-car Manufacturing Plant  
ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30 —Miss B M le P Power Indian Labour Conditions  
ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5 —Annual General Meeting  
PHYSICAL SOCIETY (in Physiological Laboratory, University College), at 5 —Prof A V Hill The Measurement and Analysis of the Heat Production of Nerve (Lecture)  
UNIVERSITY COLLEGE, at 5 30 —Sir Bernard Pares Russia and the West (Lecture)  
GOLDSMITHS' COLLEGE (New Cross), at 5 45 —Prof J F Unstead Recent Developments of the Regional Method—as applied to Teaching  
ROYAL INSTITUTION OF GREAT BRITAIN, at 8 30 —Conve-sazione  
ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8 30 —Annual General Meeting  
CAMBRIDGE UNIVERSITY (in Anatomy Lecture Room, New Museum) —Prof J J R Macleod Linaere Lecture

## SATURDAY, MAY 7

GOLDSMITHS' COLLEGE (New Cross), at 3 30 —Prof H J Fleure Social and National Ideals in their Geographical Settings—A Study of Some European Problems

## MONDAY, MAY 9

UNIVERSITY COLLEGE, at 2 —Dr W W Greg The Descent of Manuscripts (Lecture)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 5 —General Meeting  
INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6 15 —Annual General Meeting  
BRITISH ASSOCIATION OF CHEMISTS (Notts and Derby Section) (Annual Meeting) (at King's Café, Derby), at 7 15 —A W Knapp and others Discussion on the Organisation of the Profession  
MEDICAL SOCIETY OF LONDON (Annual General Meeting) (at 11 Chandos Street, W 1), at 8 —At 8 30 —Sir James Berry Fallen Idols (Annual Oration)

## TUESDAY, MAY 10

ROYAL HORTICULTURAL SOCIETY (Greycoat Street, S W 1), at 3 30 —Sir Frederick Keeble Garden Fertility (Masters Memorial Lectures) (1)  
ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section) (Annual General Meeting), at 5 —Discussion on Some Problems concerning the Prevention and Treatment of Acute Rheumatic Infection  
INSTITUTION OF CIVIL ENGINEERS, at 6 —Annual General Meeting  
BRITISH ASSOCIATION OF CHEMISTS (Birmingham Section) (at Chamber of Commerce, Birmingham), at 7 30 —Annual Meeting  
(NEW) INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS (British Branch) (at Institution of Mechanical Engineers), at 7 30 —Dr W Rosenham The Work and Objects of the Association  
ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8 30 —Annual General Meeting  
ROYAL INSTITUTE OF PUBLIC HEALTH (at Belfast) (continued on May 11 to 15)

## WEDNESDAY, MAY 11

- ROYAL HORTICULTURAL SOCIETY (Greycoat Street, S W 1), at 3 30—Sir Frederick Keeble Garden Fertility its Origin and Maintenance (Masters Memorial Lectures) (2)
- ROYAL SOCIETY OF MEDICINE (Surgery Sub-Section of Proctology), at 5—Annual General Meeting
- NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (at London School of Economics), at 5 30—Dr C S Myers Psychological and Social Factors in Business Rationalisation (2) The Dangers of Rationalisation
- SCHOOL OF ORIENTAL STUDIES, at 5 30—Dr Pran Nath Indus Inscriptions
- INSTITUTION OF ELECTRICAL ENGINEERS (Tees-Side Sub-Centre) (Annual General Meeting) (at Cleveland Technical Institute, Middlesbrough), at 7—E H E Woodward and W A Carne An Analysis of the Costs of Electricity Supply and its Application in Relation to Various Types of Consumers
- INSTITUTE OF METALS (at Institution of Mechanical Engineers), at 8—Prof F Korber The Plastic Deformation of Metals (Annual May Lecture)

## THURSDAY, MAY 12

- UNIVERSITY COLLEGE, at 5 30—Prof W R Hess The Autonomic Nervous System (1) (*Succeeding Lecture on May 13*)
- IRON AND STEEL INSTITUTE (Additional Meeting) (jointly with Staffordshire Iron and Steel Institute) (at Chamber of Commerce, Birmingham), at 6 30—Presentation of Papers
- OIL AND COLOUR CHEMISTS' ASSOCIATION (London Section) (Annual General Meeting) (at 30 Russell Square, W C 1), at 7 30—S K Thornley Development of Government Intervention and its Effect on our Industry
- OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7 30—Annual General Meeting, followed by Ordinary Meeting

## FRIDAY, MAY 13

- ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee), at 5 30—J H Driberg Economic Stages of Development in Africa
- BRITISH ASSOCIATION OF CHEMISTS (London Section) (at Broad Street Station Restaurant, E C), at 7—Annual General Meeting
- INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at Cowdry Hall, Aberdeen), at 7 30—Prof J K Catterson-Smith Everyday Uses of Electricity (Faraday Lecture)
- ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir John C W Reith Broadcasting
- INTERNATIONAL COMMITTEE ON THE HISTORY OF SCIENCE (at Paris) (*continued on May 14 to 16*)

## SATURDAY, MAY 14

- ASSOCIATION OF TEACHERS IN TECHNICAL INSTITUTIONS (Annual Conference) (at Technical College, Cardiff) (*continued on May 15 to 17*)

## The Training of Archæologists

CONDITIONS at the present moment can scarcely be regarded as propitious for any new undertaking in scientific teaching or research which looks to the financial support of the public for its funds, but the appeal for £30,000 to found an archæological institute in the University of London, which has been launched by Sir Charles Peers, and to which he made reference in his presidential address to the Society of Antiquaries on April 28, is more than justified, even if it were only on the ground of its urgency. It has the backing of the heads of the principal learned societies and other bodies in London which are interested in archæological studies, and it will receive cordial endorsement among those who are acquainted with the difficulties which, in present circumstances, hamper the organisation of these studies, not only in London, but also in other educational centres where archæology is a recognised subject of instruction.

The Board of Archæological Studies in the University of London has had the proposal for an institute of archæology under consideration for some time. It has now become urgently necessary that some decisive action should be taken at once. The plans for the new university buildings in Bloomsbury are in course of preparation, and provision is being made for the accommodation of the Institute of Historical Research and the Institute of Art. It is only fitting, and indeed it is eminently desirable, that, if the University is to have an Institute of Archæology at all, it should be in the same building. The immediate proximity of three departmental institutions dealing with subjects so closely allied will obviously add greatly to their usefulness by facilitating interchange and cross-reference in the consultation of books and other material available for study and research.

In the proposal now put forward, it is not intended that the Institute of Archæology should constitute a separate teaching school of the University. The present teaching arrangements in archæology will be unaffected, except in so far as the Institute will afford an opportunity for practical instruction in archæology along certain lines. It will be a place of training but not of teaching in the academic sense, it will be equally available for students of all descriptions from all parts of the world and in all branches of archæology, and it will be equipped under the three main heads of materials for study, laboratory, and library. Its main function will be the instruction of the student in the practical methods and technique of

archæological investigation in the field and in the archæological workshop—the workshop, that is, in the wider sense in which it covers the classification and serial arrangement, as well as the material preparation for study, of the objects accruing in the course of archæological exploration.

Archæologists have long been convinced of the urgent necessity for the establishment of such a place of training. The demand for the services of trained men, or women, in the field is now far in excess of the supply. The remarkable, not to say at times sensational, discoveries made since the War, in Egypt, in Mesopotamia, and in India, have stimulated public interest in archæological studies, with the result that it has been possible greatly to extend the field of archæological investigation, while the trend in the development of archæological theory has been such as to press on the simultaneous investigation of sites which, at one time, it might have been considered possible to postpone, as less urgent, for examination in orderly rotation.

This increased activity involves a heavy drain on the man-power of archæology—it demands a more intensive training in the direction of both a more highly specialised technical equipment and a wider comparative knowledge, not merely of the general trend of development, but also of details of cultural characteristics and manifestations in the various more or less related provinces of archæological discovery. It would, for example, be hazardous, at the present stage of our knowledge, to attempt to fence off as irrelevant any one province between Western Europe and China at certain periods of pre-history. Such conditions, obviously, make heavy demands on the knowledge of an archæologist outside his special province.

It is, however, in the development of technical methods, both of excavation and salvage, that progress recently has been marked, and in which much is required of the investigator. Not so very long ago, the leader of an archæological expedition often had to improvise methods of salvage and recording his discoveries on the spur of the moment. Now the worker in the field must be equipped with a wide range of technical knowledge, embracing more than a mere nodding acquaintance with the chemical and physical properties and reactions of the material with, in, and on which he works, or which it may be possible or expedient for him to employ in given conditions. So great, in fact, has been the advance in these requirements that a recent report on an archæological investigation refers to the work of a predecessor on the same site only twenty years before, who for that time

was highly trained, in terms which might have been applied to the Dark Ages.

The work of British archæologists in the field, is generally conceded, and not without reason, holds a foremost place in the scientific study of archæology throughout the whole world on the score of its vision, its meticulous care in carrying out the work of excavation, and in the accuracy of its observation and record. The credit for this is largely due to great excavators such as Sir Flinders Petrie and Sir Arthur Evans, to name two of the best known only. By their example, by precept and in many instances by actual instruction, the leaders in archæological research have inculcated scientific methods of investigation in younger men who have carried on their tradition and helped to develop its principles. British archæology, too, has been fortunate in that bodies such as the Egypt Exploration Society and the Schools of Archæology in Egypt, Athens, Rome, Palestine have been able by the continuity of their operations from year to year, to afford an unrivalled field of training to the archæological recruit, such as for long was open to the archæologist of almost no other country.

Leaders of archæological expeditions, however, are busy men, and the calls on their time, even the calls of day-to-day routine, are heavy and seem to be on the increase. It is becoming more and more difficult for them to devote themselves in an appreciable degree to the training of younger colleagues in carrying on the work. The conditions of the past, in fact, are no longer possible, nor are they adequate either to the needs of a modern scientific expedition or of the individual. A training institution of some kind must, perforce, be provided in their place. To a limited extent the British Museum has been able to meet the deficiency in one branch of training, the technique of cleaning, preserving, and repairing such material objects as are usually found in the course of excavation, by generously placing its laboratories at the service of a limited number of students. But to act as a school is not the function of a museum, nor can it display for the benefit of students the endless series of objects—potsherds, for example, of which there is a valuable but inaccessible store in London—which are essential to the needs of the beginner in archæology, but of little interest to the general run of those who wish to consult the collections of a museum.

In this connexion, it must be pointed out that the museum worker in archæology is in need of training equally with the man in the field. Ideally each should know something of the work of the

other, and conditions similar to those which militate against the instruction of juniors in the elementary principles of practical archæology while in the field are becoming increasingly prevalent in our museums

A brief reference must be made to the needs of comparative study. From the nature of the case, this cannot be carried to any great length in an institute such as is contemplated, nor is it probable that a minutely detailed treatment will be necessary. Provision, it is suggested, will be made for the study of the cultural development of the different centres by the display of original material, supplemented by series of casts sufficiently complete to give a general conspectus of the artistic tradition in each. The use of casts is a very necessary measure in view of the scattered distribution of archæological material in widely separated collections, and the increasing sentiment against the export of antiquities from their country of origin.

Nothing would appear to have been said, at least as yet, as to the possibility of any provision by the Institute of facilities for practical work in the field, that is, in actual excavation—beyond question an element of the first importance in any scheme of training which sets out to be practical. The participation of the students of one of the constituent colleges of the University of London in a succession of small 'digs' on archæological sites proved eminently successful in stimulating keen interest, and in at least one case revealed an unexpected *flair* for archæological investigation. No doubt, even if it should be found impracticable for the Institute itself to work on these lines, arrangements with other bodies carrying out excavations within a reasonable distance of London might well be possible, especially as facilities for observation and participation in the work of excavation have already been granted students on at least one site.

The fact that a concrete proposal for a school of archæological training has been put forward in connexion with the University of London renders nugatory any discussion whether a more suitable situation or greater facilities might have been obtained elsewhere, whether at Oxford or Cambridge with their valuable archæological collections and their powerful if imponderable traditions of the study of antiquity. In any event, the congregation of the great national collections in London would go far to weigh down the scale, while the attraction to overseas visitors of an Institute which throws open its doors to all comers gives the central position of London in relation to the outside world an irresistible claim.

### The Butterflies of America

*The Butterfly Book a Popular and Scientific Manual, describing and depicting all the Butterflies of the United States and Canada* By Dr W J Holland (The Nature Library) Pp xii + 424 + 77 plates (Garden City, N Y Double-day, Doran and Co, Inc, 1931) 10 dollars

THE second edition of Dr W J Holland's "Butterfly Book" brings the subject matter up to date. The text has to a large extent been rewritten and a number of plates have been added, all the species of butterflies occurring in America north of Mexico being depicted, with the exception of a few obscure or doubtful ones. The introduction deals with collecting, breeding, preserving, and classifying specimens, and with manuals, catalogues, and check-lists of North American butterflies. The generic descriptions are illustrated by text-figures of wing-venuration, and occasionally by some additional detail of structure. The descriptions of species are kept as short as possible, the life-history, if known, being added, and the distribution of each species and variety noted. The interpolated chapters of an anecdotal or educative nature are very pleasing interruptions of the necessarily dry and monotonous descriptive text. A complete alphabetical index greatly facilitates the use of the book.

In estimating the merits of a volume of this kind, the reviewer has two lines of approach, giving views at two different angles. the critical examination of the subject matter, and the estimation of the influence of the book on the public. The "Butterfly Book" is primarily a manual for the lover of Nature who devotes his leisure hours to Lepidoptera in one way or another. Its great value consists in supplying a want for a non-expert public which requires a guide in its search for information.

It is essential for the welfare of the human species that this point of view should be understood and acted upon by the advanced man of science. Many biologists of our time are unfortunately only too prone to consider their own corner in science to be the only one worth occupying, forgetting that although the inevitable overcrowding of the earth will necessitate the application of biological principles to human relations, biology will not attain the foremost position it ought to occupy in all councils governing life unless there is a large body of people willing to listen to the biologist and capable of understanding the bearing of his teaching. It is of little avail to try to educate reluctant or even hostile governments steeped in antiquated

notions of the interrelation of human beings with each other and with the environment

The 'mere' collectors are the important persons, and the more there are of them the easier it will be to introduce an outlook on life conforming to the principles of biology. Dr W J Holland's book is one of the best means of attaining this much-desired end. It is most pleasing and encouraging to read in the introduction that more than 65,000 copies of the first edition have been distributed—an astonishing result. It may safely be predicted that the second edition will also be a 'best seller'. We have here proof that, in North America no less than in Europe, there is a large biologically-minded public, it is for the advanced biologist to encourage it and to be its leader.

The specialist in Lepidoptera will welcome the new edition particularly on account of the many figures of types depicted on the additional plates. As taxonomists, whether amateur or professional, were not (and are not) always careful in the labelling of the specimens on which they based descriptions of new species, and as the method of selecting one specimen as type was formerly not in general use, one or the other reputed type may in reality be an individual added to the collection after the publication of the original description. Dr Holland states his reasons for accepting as type or typical this or that specimen figured, and if a sceptic should not agree with Dr Holland in every instance, he will have to defeat Dr Holland by positive arguments, which is a much more difficult task than the mere expression of doubt.

The nomenclature employed is conservative, Dr Holland being particularly emphatic, and rightly so, in rejecting the Tentamen of Hubner, a printed questionnaire of 1805 containing names which some authors, mistaking them for generic names, have adopted, causing thereby much unnecessary confusion. The author divides the butterflies into seven families: Nymphalidæ, Libytheidæ, Riodinidæ, Lycænidæ, Pieridæ, Papilionidæ, and Hesperidæ. The reviewer heartily agrees with him in uniting the Danainæ, Satyrinæ, etc., with the Nymphalidæ in one family, all these butterflies being indeed nothing but diverse developments of one large branch separate from all the other butterflies. The genus *Libythea*, which has a lonely position as occupier of a house of its own, should also have been placed with the Nymphalidæ, but the error, a hundred years old, of considering it nearly related to the Riodinidæ, dies hard, and Dr Holland here follows the ill-considered opinion of the overwhelming majority of lepidopterists, at

whom *Libythea* itself disdainfully turns up its long nose. In the species and varieties, the author adheres to the convenient but scientifically incorrect method of treating the accidentally first-described form of a species as *the* species, and the other forms, which as a rule are really co-ordinated with the first-described one, as varieties of it—a method which leads to phylogenetic inconsistencies.

However, these points do not impair the usefulness of the "Butterfly Book", either for the beginner or for the expert, and will deter nobody from acquiring the handsome volume. Considering the large number of coloured plates, the book could be offered at the moderate price of 10 dollars only in expectation of very large sales. Dr Holland, who finished the manuscript on his eighty-second birthday, is most heartily to be congratulated on this achievement. It was a laborious task successfully carried through in consequence of the author's great experience, boundless energy, and deep love of Nature.

KARL JORDAN

### The Fascination of Things Inanimate

*Inorganic Chemistry* By Prof T Martin Lowry.  
Second edition. Pp xiv + 1101 (London: Macmillan and Co, Ltd, 1931) 25s net

A NEW edition of Lowry's "Inorganic Chemistry" is a welcome event, especially since the author, taking advantage of the necessity to reset the text, has materially altered and improved its structure so as to take full account of many developments in chemistry during the last ten years. He evidently believes that anything which is really true is amenable to simple explanation, if we will but take the trouble, and a commendable feature of his book, a direct outcome of clear thought and plain words, is that it presents satisfactorily many matters which are new or are commonly regarded as difficult.

The historical and introductory chapters remain much as before, and a reperusal of them strongly reinforces the old impression of their sound and attractive character. To begin, as the author does, with substances and their fundamental properties, and pass on at once to practical methods of purification and tests of purity and to means of identification of pure substances, is indeed to put first things first. It is too easy for the pedagogue to forget that the primary duty of the chemist is to know and handle all forms of matter. On this point the author is very sound. With quiet, sustained enthusiasm, which may be inferred from the care and clarity of his descriptions, he develops

and displays the sheer interest and beauty inherent in the curious, unexpected, even perverse behaviour of inanimate material

From general fundamental ideas, the author passes to consider in turn salts, alkalis, and acids, the calcination of metals, chalk and lime, the burning of carbon and the composition of fixed air, and the burning of hydrogen and other combustible gases. This brings in, naturally, vividly, and accurately, a great part of the earlier history of chemistry, and provides material and reason for the consideration that follows of the laws of chemical combination and the atomic theory.

A review of the properties of gases (which is particularly well done) leads up to Avogadro's hypothesis and the Cannizzaro method for atomic weight, the application of which is illustrated very clearly by a table of data yielding the atomic weights of hydrogen, oxygen, chlorine, and carbon. This leads to a consideration of other methods of determining molecular and atomic weights, and a discussion of solutions and the colligative properties of dissolved substances whereby their molecular weights are ascertained. Having thus touched, naturally and effectively, upon many essential principles usually branded as 'physico-chemical', we pass on to the distillation and crystallisation of mixed liquids, illustrated by some clear and well-chosen phase diagrams and photomicrographs, and to an outline of the phase rule. Then, by way of electrolysis and typical cells, the author introduces the ionic hypothesis, not shirking the theory of complete ionisation, and discusses the types of valency. As the last item in this review of general theory there is an admirably clear and interesting chapter on the form and structure of crystals.

Reading this part of the book, about a quarter of the whole, one has the sense of a smooth, orderly, and efficient progression of argument. The doubts and pitfalls are not evaded, they are, indeed, clearly and carefully pointed out, but, using what is firmly established, the foundations of chemistry are neatly and strongly laid.

In Part II of the book, devoted to the non-metals, the matter presented is for the most part that usually found in the larger textbooks. We may remark, however, the inclusion of ortho- and para-hydrogen, a good section on flames (though it seems a pity to omit a diagram of the Smithells flame-separator), a reference to dense ice, and good brief outlines of our knowledge of free radicals and of the theory and practice of the liquefaction of air and hydrogen. As examples of the care that

has been taken to bring the matter up to date, the inclusion of fluorine monoxide and hydrogen pentasulphide may be cited. Special praise must also be given to a very full and clear account of the chemistry and constitution of the silicates.

Since authors (and critics) are human, some points may be found, of course, for criticism. For example, the failure to mention any commercial ozoniser, the omission of any reference to the preparation of pure chlorine by thermal decomposition of auric or platonic chloride or to the practical methods of making perchloric acid from sodium or ammonium perchlorate. Also, it might be said that the chlorides of iodine are dismissed too lightly and without any reference to the monotropy of the monochloride, that the most practical method of making chlorine monoxide, by dehydration of hypochlorous acid, is not mentioned, and that the use of the term "silicfluorides" is pedantic. But these, after all, are minor faults—it is, perhaps, merely a matter of opinion whether they are faults at all—and they do not detract appreciably from the outstanding merit of the book.

The latter half, or thereabouts, of the book deals with the metals, which are divided, for convenience, into the "typical" metals (Part III) and the "non-typical" (Part IV). In Part III, after a general review of the metallic properties, we pass at once to a discussion of classification and atomic constitution and structure, which is particularly clear and interesting. Thereafter the metals of the alkalis and alkaline earths, beryllium and aluminium, tin and lead, and arsenic, antimony, and bismuth are described. At the end of this part, not at the beginning with the discussion of atomic constitution, there stands in rather curious isolation a table showing the electronic configuration of the elements. One is a little puzzled to know why it should be here, unless it is to be at hand for reference in the discussion, with which Part IV. begins, of the general characteristics of the transition elements. After the remaining metals are disposed of, the book concludes with a short but very good chapter on the radioactive elements.

Because of good, clear type and thin but reasonably opaque paper, the book, despite its thousand pages, is of moderate size and weight and easy to read and handle. It has a good index. As textbooks go, it is expensive, but it is well worth its price. The numerous and well-chosen diagrams of apparatus and plant are particularly clear, and the author's delight in crystals is shown by the many excellent photographs of mineral specimens. In fact, his enthusiasm for one very fine crystal

of fluorite (combined, no doubt, with a momentary lapse of memory) has betrayed him into putting it in twice, as Fig 125 on p 337 and as Fig 235 on p 736

This, in short, is a chemical work of that rare kind which is both scholarly and humane, and as such it may be commended warmly and without reserve to all serious students of the science and to those who may influence their reading

### Physics and Chemistry of the Soil

*The Soil an Introduction to the Scientific Study of the Growth of Crops* By Sir A D Hall Fourth edition, revised and enlarged Pp xvii + 388 (London John Murray, 1931) 9s net

THE reissue of this well-known textbook will be welcomed by all engaged in agricultural teaching. Appearing first in 1903, it had passed through three editions, with many reprints, by 1920, and has now reached a fourth edition. These facts alone indicate plainly the welcome given to the book in the past, and the reason for this is not far to seek. It demands no wide knowledge of the pure sciences on the part of the reader. It accepts the average student of agriculture as his lecturer generally finds him—a man anxious to know something of the fundamental scientific facts underlying his profession but by force of circumstances quite unable to undertake a thorough scientific training before beginning his more technical studies.

As the author stated in his original introduction, the book is “primarily intended for the students of our agricultural colleges and schools, and for the farmer who wishes to know something about the materials he is handling day by day.” This purpose it serves admirably, but its use need not be limited to this type of reader. A teacher might well put it into the hands of the budding agricultural chemist, after his training in pure science, as a general survey of our knowledge of the soil. To such a student its extremely readable character makes it a useful introduction to the more highly specialised publications dealing with particular aspects of the subject.

The new edition follows fairly closely the general lines of previous issues, though a considerable amount of new material has been incorporated. Starting with a description of the soil-forming processes, the author deals successively with the physical and chemical properties of the soil, the soil micro-organisms and the processes dependent on them, the retention of fertilisers, base exchange, the

loss of soil constituents by leeching, soil acidity, causes of fertility and sterility in soils, and, finally, the classification of soils into types. Never losing sight of his original object, the author brings each subject within the grasp of the reader he has in view and illustrates the general principles by an abundance of examples from both scientifically controlled field experiments and farming practice.

It is interesting to note the infiltration of recent advances in soil science into a book of this type. Extensive treatment of such subjects as soil colloids, hydrogen ion concentrations, soil profiles, and the classification of soils founded on the work of the Russian school would obviously have been impossible, but each of these subjects receives mention and finds its place amongst the older material.

A short bibliography, useful to the student as a guide to wider reading, has been added, and its value is enhanced by the care which has been taken in the selection of the items. A short index completes the volume.

As might be expected, the book is excellently produced and is singularly free from errors. The volume in its new form certainly maintains the high position it has made for itself in the past.

H A D NEVILLE

### Fundamentals of Ophthalmology

*Text-Book of Ophthalmology* By Dr W Stewart Duke-Elder Vol 1 *The Development, Form and Function of the Visual Apparatus* Pp xxix + 1124 + 7 plates (London Henry Kimpton, 1932) 63s net

THERE have been several good manuals of ophthalmology written by Englishmen. The first of the modern, that is, post-ophthalmoscopic, period was written by the late Mr Edward Nettleship. It was a very remarkable book, which, like its contemporary, Gowers's “Medical Ophthalmology”, well merits perusal even to-day, for it is packed with the observations of a very great scientific clinician. Doubtless a larger and more comprehensive textbook would have been written in due course if it had not been for the appearance of Fuchs's textbook, which was soon translated into English and is still universally read. The English version was edited and published in America, and has undergone transformations in later editions which are not all improvements. As so often occurs, ill-digested new material has been invaginated into the text in such a manner as to obscure its balance and perspective without making it satisfactorily encyclopædic. The

Germans have published more comprehensive works, such as the gigantic "Graefe-Saemisch" in countless volumes, still unfinished, and likely ever to remain so. More recently, they have issued the first three volumes of a so-called "Kurzes Handbuch", which, when the seven volumes are completed, will cost £49!

The time is therefore ripe for a new textbook, and if the final two volumes are as good as the first, the need will be well satisfied by Duke-Elder. This first volume deals with the anatomical, physiological, and psychological foundations of ophthalmology. It is the most complete and most up-to-date résumé of our knowledge of the subject. The separate sections are devoted to phylogeny, anatomy and comparative anatomy, ontogeny, physiology and biochemistry, optics, the physicochemistry of vision, the physiology of vision (visual sensations), and the psychology of vision (visual perceptions). Though each of these sections demands specialised study and very diverse mental abilities, the author has shown himself well able to surmount each successive obstacle. He possesses an unusual capacity to segregate the salient points from masses of literature, to arrange them in logical order, and to impart some of his own enthusiasm to the reader. For this is no dry-as-dust compilation. He has taken a leaf out of the late Prof. Bayliss's book, and by judicious historical and biographical notes, accompanied by portraits of outstanding workers in the various fields, he has made the book eminently readable and attractive.

The book is also noteworthy in providing a concise account of the author's own valuable contributions to the physiology and biochemistry of the eye. These researches have so important a bearing on general physiology, especially that of lymph formation, that the attention of physiologists should be directed specifically to them. The investigations of Leber, confirmed and extended by Starling and others, proved that it was unnecessary to predicate any true secretory activity to account for most of the facts relating to lymph formation in the eye and the intraocular pressure. These workers propounded a filtration hypothesis, although they were fully conscious of the lacunæ in their knowledge of other biochemical and biophysical factors which undoubtedly play a part. By a masterly application of the methods of modern biochemical technique, Duke-Elder has shown that these factors play indeed the preponderant rôle. By an exhaustive experimental investigation of the hydrostatic conditions and the chemical constitution and physical characters of the intraocular fluid,

he has shown that every factor is consistent with the view that the intraocular fluid is a dialysate in equilibrium with the capillary blood.

Without in any way depreciating the value of these researches, it may be pointed out that no more than the filtration hypothesis do they reach finality. Indeed, to some extent, they introduce fresh difficulties. For example, they throw back the peculiarities of lymph constitution and formation in different organs and different species to differing permeability of the capillaries. "The variation is, of course, a biological adaptation to the needs of the tissue concerned" (p. 428), which savours of a teleological *deus ex machina*. There are also many pathological facts which can scarcely be explained on our present knowledge. None the less, the work is of the first order in scientific insight and technical accomplishment.

The book is beautifully produced and illustrated.

### Short Reviews

*Das periodische System in neuer Anordnung mit Tabellen über Fünfzehn physikalische Konstanten in Anordnung nach der Ordnungszahl der Elemente und nach der Grösse der Konstanten.* Von Dr. Darwin O. Lyon. Zweite Auflage. Pp. vi + 40 + 4 Tafeln + 23 Kurven. (Leipzig und Wien: Franz Deuticke, 1931.) 8 gold marks.

IN attempting a detailed study of the magnetic properties of all the elements, particularly in relation to their relative abundance in the earth's crust, in the hope of being able to throw light upon the process of their evolution, the author of this essay has gone to considerable trouble in drawing up an elaborate set of tables, in which a number of physical constants of the various elements are arranged not only in the order of atomic numbers but also in order of magnitude. The Thomsen-Bohr arrangement of the elements is given in Table 1 for reference. Table 2 contains some new features in the familiar scheme of 18 groups and 8 periods. Thus, instead of atomic weights, the following values are inserted: atomic number, electrical resistance, magnetic susceptibility, density and melting point, whilst dia- and para-magnetic properties are indicated by means of shading. The peculiar character of oxygen, which is strongly paramagnetic in itself, though diamagnetic in many of its compounds, is denoted by striped shading.

Much more useful arrangements will, however, be found in Tables 3 and 4, which form the most notable feature of the work. In Table 3 will be found the following physical constants of the elements, arranged in the order of their atomic numbers: atomic number, atomic weight, density and thermal expansion for both solids and liquids, melting and boiling points, latent heats of fusion and of volatilisation, specific heat, electrical resistance, magnetic susceptibility, entropy, and sound

conductivity, the values for the last-named property being restricted to twenty-four elements. Table 4 contains all these constants, but arranged for each property in strict order of magnitude, and, in addition, certain ratios of these constants are tabulated. The different constants have also been plotted graphically after the manner of Lothar Meyer's well-known graph of atomic volumes.

*The Botany of Crop Plants: a Text and Reference Book.* By Prof. W. W. Robbins. Third edition, revised. Pp. x+639. (Philadelphia: P. Blakiston's Son and Co., Inc., 1931.) 4 dollars.

THE value of this book, first published in 1917, as a classroom textbook is testified by the fact that a third edition is now called for. The undue inflation that is frequently caused by the inclusion of fresh material in repeated editions is here obviated by the elimination of most of the tables and text matter dealing with the distribution and yield of crop plants. The treatment is essentially botanical, not horticultural, and such matters as methods of cultivation and the soils appropriate for various crops do not come within its scope.

The book is prefaced by a short botanical outline, providing a revision of fundamental points necessary for the better understanding of the main discussion. Crops are dealt with according to their families, and the range of data discussed varies according to the type of information which is most useful in each individual case. The practical and economic aspects are kept in view throughout, and the references at the end of each chapter provide useful guidance to those students who desire more detailed knowledge of particular crops. Where necessary, keys are given for the classification of the different genera, species, or varieties. Many of these keys are original, and no attempt is made at uniformity, each case being dealt with on its own merits.

The illustrations deserve a special meed of praise for their clarity, many of them being simplified annotated line drawings, which convey a distinct impression of the special points they are intended to exemplify.

*Polyphase Induction Motors: their Theory, Calculation and Application.* By Louis Lagron. Translated by R. C. Simpson and Dr. M. G. Say. Pp. xiv+218. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1931.) 15s. net.

READERS of this book should have a good knowledge of electromagnetic principles and a working knowledge of the ordinary vector methods of discussing alternating current problems. As the book discusses only polyphase induction motors, its scope is scarcely wide enough for the student, whose library is naturally somewhat limited in size. The reasoning is easy to follow, but it is only mildly interesting to the engineer, as few of the difficulties of the theory are pointed out.

For mining purposes and for work in agriculture these motors are widely used, as they are not easily damaged. They were originally called 'asynchronous motors', but this led to confusion with

'a synchronous motor', and so the phrase 'non-synchronous' motor has come into use. The translators use both terms. The great advantage of an induction machine is that it requires no direct current excitation. If we drive it by means of external power above synchronous speed it becomes a generator. Thus it can be used for braking purposes in lifts and trains and, under certain conditions, power can be returned to the lines. Brief descriptions are given of cascade converters and frequency changers.

*But for the Grace of God.* By J. W. N. Sullivan. Pp. 223. (London: Jonathan Cape, Ltd., 1932.) 7s. 6d. net.

IN earlier works Mr. J. W. N. Sullivan has exercised his literary gifts in making science intelligible to readers who are prepared to give thoughtful attention to novel conceptions and complex relationships. He has been very successful in his mission, and has rendered good service to science by his writings. In the present volume Mr. Sullivan tells the story of his life and reactions—physical and psychological. He intended at one time to present the events and experiences in the form of a novel, but decided eventually to adopt the autobiographical style. The emotional episodes are delicately described, but there is nothing particularly unusual about them even to the men of science who are said to be "exceptionally incomplete as human beings." Many thought-provoking aphorisms are, however, to be found in the book, such, for example, as "The attempt to teach mathematics by making it as 'concrete' as possible is killing to the naturally mathematical intelligence", and "It is the scientific man, not the poet, who is the dweller in dreamland." As a personal revelation of the development of a scientific mind, the book is well worth reading.

*Seventy Years in Archaeology.* By Sir Flinders Petrie. Pp. viii+284+26 plates. (London: Sampson Low, Marston and Co., Ltd., n.d.) 18s. net.

AT least one reader of Sir Flinders Petrie's autobiography must admit to closing the book with a feeling of disappointment. It falls between two stools. The general reader, who is no Egyptologist, will look to its author in the hope of gaining perspective in a review of archaeological discovery in Egypt during the last fifty years, but he will find that the book confines itself strictly within the limitations of its title as a personal record of work in the field year by year since 1880, when Sir Flinders first went to Egypt. The Egyptologist, on the other hand, will regard it as too brief, too summary in its descriptions, to serve as anything more than a reminder of where the author was digging in any given year. From one who is our greatest pioneer and systematiser in archaeological exploration, the most prominent and the most striking figure in British archaeology in the present century, a broader view of his own work and its relation to archaeological studies might legitimately be expected.

## The Land Utilisation Survey of Britain

By Dr. L. DUDLEY STAMP, Director of the Survey

AFTER about a year spent in preliminary experiment, the Land Utilisation Survey of Britain, aided by an initial grant from the Rockefeller Research Foundation administered by the London School of Economics, began work with the appointment of its first organising secretary in October 1930. The genesis of the scheme, its aims and objects, have been explained at some length in papers read before the Royal Geographi-

cal Society<sup>1</sup> and the Royal Scottish Geographical Society.<sup>2</sup> It may be said very simply that the aim of the Survey is to make a cartographical record, complete for the whole of Great Britain and referring to the years 1931 and 1932, of the uses to which the surface of the country is being placed at the present time.

the discretion of the surveyor whether each piece of land is merely marked with the initial letter, as given below, or lightly coloured.

(1) Forest and woodland, marked F; if coloured, a dark green. Forests and woodlands are already marked on the six-inch maps, but it is necessary, especially where the maps are rather out of date, that each area should be checked, and special care is required to include newly planted areas. After

FIG. 1.—Portion of Ordnance Survey map, 6 in. to 1 mile, with lettering inserted by Land Utilisation Survey. (Reproduced by permission.)

cal Society<sup>1</sup> and the Royal Scottish Geographical Society.<sup>2</sup> It may be said very simply that the aim of the Survey is to make a cartographical record, complete for the whole of Great Britain and referring to the years 1931 and 1932, of the uses to which the surface of the country is being placed at the present time.

The record is being made on the maps published by the Ordnance Survey on the scale of six inches to the mile, since on these maps every individual field is already marked (Fig. 1). There are the equivalent of about 22,000 quarter-sheets of these maps, each representing six square miles, to be covered for the whole of Britain, and, broadly speaking, each quarter-sheet requires about two days' work. After a number of preliminary experiments, the following simple classification was adopted. It may be mentioned that it was left to

consultation with the Forestry Commission, the following classification of forests was adopted: (a) High forest—big trees sufficiently close for their crowns to touch, and useful for timber production. (b) Coppice, or coppice with standards—woodland that is cut over every few years for fencing, posts, etc. (c) Scrub—small bushes or trees unfit for cutting. (d) Forest felled and not replanted. Thus each piece of forest or woodland has a lettering, Fa, Fb, Fc, and Fd, and it is then also possible to distinguish coniferous, c, deciduous, d, and mixed, m (Fa<sup>d</sup>, etc.).

(2) Meadowland and permanent grass, marked M and coloured light green. It is important that rotation grass should be excluded from this category.

(3) Arable or tilled land, including rotation grass and fallow, marked A and coloured brown.

Some areas of arable land are quite definitely used as market gardens, which are then further distinguished by the letters *MG*, but it was not felt possible to make a separate category for market

marked *G* and coloured light purple. Houses with gardens sufficiently large to grow a few vegetables or even flowers come in this category, because the area, though producing comparatively little, is still productive. Allotments are included in this category since they are merely gardens at a distance from the worker's house. Orchards are usually separately distinguished on the six-inch map, and so the symbol combined with the letter *G* readily distinguishes them; but if the ground is used for grazing, the symbols may be combined *GM*, or where used for fruit and ground crops *GA*.

(6) Land agriculturally unproductive, marked *W* and coloured red. This category includes not only buildings, yards, mines, cemeteries, etc., but also purely waste land. Many enthusiastic surveyors have been able to add a great deal to our knowledge of the utilisation of the countryside by definitely stating what is the actual character of land marked *W* on their maps.

It will be seen that the scheme is a simple one, and for that reason the survey is being carried out very largely by school children, as an educational exercise, in all parts of the country. Indeed, it may be said that the Land Utilisation Survey has two aspects and two objects. The first is the value of the work as an educational exercise, and the whole idea grew originally out of the work of the Regional Survey Committee of the Geographical Association. The more progressive schools throughout the country have for many years been carrying out local regional surveys, and on all hands it was obvious that the training in accurate observation which was entailed and the interest in local environment which was aroused—and invariably led to a remarkable realisation of civic consciousness—afforded an objective in itself. It was only to be regretted that all the rising generation should not be able to share in such an

FIG. 2.—State of Land Utilisation Survey of Great Britain to Feb. 18, 1932.

gardens, because numbers of tracts of arable land are only used for market gardening purposes occasionally.

(4) Heathland, moorland, commons, and rough hill pasture, including swamp and marsh pasture. These are marked *H* and coloured yellow.

(5) Gardens, allotments, orchards, and nurseries,

exercise. Hence it was felt that if a nation-wide survey on simple lines could be organised it would heighten the value of existing regional surveys and give a new incentive to those who had not yet undertaken such work, by permitting the participants to realise that they were really doing part of a great nation-wide work.

It may be said at once that the enthusiasm with which the scheme was received by educational authorities almost throughout Great Britain has been remarkable, and about two-thirds of the counties of England and Wales have been organised locally by directors of education. As the accompanying map (Fig. 2) shows, large areas have been completed, and testimony is unanimous as to the educational value of the work.

In the second place, there is the permanent value of such a survey. It must be said at the outset that the Land Utilisation Survey is an entirely independent body and has no connexion with any government department or with any political party, and that the inception of the scheme at a time when land valuation was a subject for Parliamentary discussion was purely accidental. Despite the rapidity with which changes in agricultural practice in Great Britain are taking place—for example, there is now less than half the area under the plough that there was fifty years ago—it is a fact that no record is available as to the exact areas over which the changes are happening. Statistics are available on a county basis and, in manuscript, on a parish basis, but in the absence of cartographical record it is impossible to evaluate the relative importance of the factors which are causing the change in a given locality. In some areas it may be soil, in others climate. It may be elevation or aspect, accessibility, or merely the progressiveness or lack of progressiveness, as the case may be, on the part of the farmer that has determined the changes in local agricultural practice. It is certain that, if a record of this character can be made for the whole of Great Britain, agricultural economists in the future will have an important basis on which to work.

It has been urged that the volunteer observers lack the training with which to make sufficiently accurate observations. To this there are several answers. In the first place, the scheme is a simple one, and on all hands where there are difficult points the advice of the farmers themselves is being sought and given willingly. In the second place, there is a ready check, in that separate sheets

of the six-inch map by different surveyors must fit along the edges where they join, and if there is a disparity in observation, this is at once apparent. In the third place, trained observers are checking the results as they are obtained by making traverses across the sheets.

The map reproduced as Fig. 2 shows the present state of the work. Two things deserve emphasis. First, thanks are due to those who have so nobly assisted up to the present date, when more than four thousand sheets have been completed and returned to the central office, but there are still gaps in the scheme, and in a number of cases the organisation of a whole county is a matter of most urgent necessity. Broadly speaking, it is found that there must be at least one really keen person on the spot for the work to be successful. It is obvious also that any serious delay in the completion of remaining tracts will cause work already done to be vitiated to a considerable extent, for, to be of value, the record should be complete for the years 1931 and 1932. In many of the areas shown on the map as in charge of volunteers there is the need for additional volunteers to fill in remaining tracts. It may be said that the maps are supplied at a reduced rate of 1s 6d each to those volunteers who wish to keep them when completed. They are merely forwarded to the central office and there copied by a photostat process. The maps themselves are retained at the central office if the surveyor does not wish to purchase them.

The Survey's headquarters are at 18 Houghton Street, W.C.2, and are open daily from 10 to 5, and inquiries are welcomed, by letter and in person. The secretary is Mr. E. C. Willatts, and the advisory committee of the Survey includes representatives from the London School of Economics (in the person of Sir William Beveridge), the Ordnance Survey, the Land Agents' Society, the County Councils Association, the Boy Scouts' Association, whilst agriculturists are represented by the director of Rothamsted Experimental Station (Sir John Russell).

### Vortex Motion in Vibrating Columns of Air

ONE of the most familiar and fascinating experiments in acoustics is that initiated by Kundt in 1866, in which the vibrations of an air column enclosed in a glass tube are revealed by means of a fine powder such as cork or lycopodium. Almost everyone is familiar with the manner in which the dust collects in little heaps at the nodes, thereby providing a simple means of estimating the velocity of sound in the gas enclosed in the tube.

An interesting secondary phenomenon also is the formation of a series of ridges or striations of dust lying across the axis of the tube. An attempt to explain this peculiar formation was made in 1891 by W. König. His theory, based on attractions and repulsions between spheres in a vibrating fluid, was universally accepted until the present

time. Even Rayleigh found nothing in it to criticise.

In two papers recently published,\* Prof. E. N. da C. Andrade has thrown fresh light on the subject in a somewhat startling manner. In the older experiments the observations of the striations were always made under static conditions, that is, after the air vibration had ceased, instead of in the dynamic state whilst the air was in vibration. Not only this, but also the method of excitation was not always maintained for a period sufficiently long for the motion to reach a final stable condition, nor was the amplitude of excitation kept uniform. Prof. Andrade remedies all these defects in

\* *Proc. Roy. Soc. A*, 134, pp. 445-470, 1931, and *Phil. Trans. Roy. Soc. A*, 230, pp. 413-445, 1932.

technique by the simple, but very effective, expedient of using a vibrating diaphragm driven by the alternating current from a thermionic valve oscillator of controllable frequency and current output. By such means he has demonstrated that even very small cork dust particles are unsuitable as true indicators of vibratory air motion. Instead of behaving as tracing points they act as obstacles which initiate local vortex motion in the vibrating gas. Consequently, smoke particles are used as a means of studying the true movement of the air in a dust-free tube, suitable precautions (water jackets, etc.) being taken to prevent circulations due to convection currents. A series of beautiful photographs reveals regular circulations of air in the tube, the general drift being from antinode to node along the wall, returning up the centre of the tube. The resonant air column is divided into half wave-lengths by the regular drift-motion of the gas. The form of the stream lines agrees fairly well with Rayleigh's approximate theory.

An entirely novel and most important application of the air vibrations in the resonant tube is made by Prof. Andrade when he utilises the phenomenon to investigate vortex motion around obstacles in the vibrating air. By means of a specially designed tube, and making use of tobacco smoke (from a "cheap cigarette") to indicate the fluid flow, a series of photographs has been taken to show the formation of vortices around objects of simple geometrical form—spheres and cylinders of various diameters. The conditions of formation of the vortices are studied, in particular the critical velocity necessary to initiate vortex motion. In order to determine this velocity it was necessary to measure the actual amplitude of the air vibration, observing the individual smoke particles by means of a microscope. This measurement is in itself a

notable achievement, forming as it does the basis of a standard source of sound. The results obtained for the critical velocity in alternating flow are, considering the difficulty of the experiment, in good agreement with similar measurements by other observers for steady flow.

The second of Prof. Andrade's papers deals more particularly with the general behaviour and grouping of solid particles under the influence of air vibrations in tubes. The phenomena observed, antinodal discs, primary and secondary striations, are shown in a most convincing manner to be due to vortex motion and general circulation set up when the air-particle velocity in the tube exceeds the critical value. König's theory is conclusively proved to be untenable as it entirely ignores such vortex motion. It would require too much space to enter into details of the wonderful arrangements of the irregular particles of cork dust, the spherical particles of carnauba wax and the vortex streams around obstructing particles lying in the tube. Actual photographs of the motion of minute dust particles demonstrate the alternating motion superposed on the general drift.

Acoustics has assuredly taken a new lease of life in recent years. The two papers by Prof. Andrade briefly summarised in the foregoing remarks show in a most striking manner how even an ordinary textbook experiment in sound may be revived to yield most interesting and valuable information. The old Kundt's tube experiment now provides a means not only of measuring sound velocity, but also of producing vibrations of known amplitude (a standard source of sound), and of studying vortex motion. One cannot help wondering, however, how many "cheap cigarettes" Prof. Andrade must have smoked "in the cause of science."

### Neanderthal Man in Palestine

A CABLEGRAM has been received from Mr. Theodore McCown, who, in the temporary absence of Miss Dorothy Garrod, is directing the exploration of caves in Mount Carmel, announcing the discovery of fossil remains of three individuals of the Neanderthal species of mankind. The discovery thus announced is of more than usual importance, it brings to a successful issue a search which has been conducted in Palestine since 1925, first by the British School of Archaeology and latterly by a combined expedition fitted out by that School in conjunction with the American School of Prehistoric Research. Miss Garrod is in charge of the combined expedition, and to her must go the chief credit.

To appreciate the importance of the discovery just announced, it is necessary to recall the sequence of events which have led up to it. The first discovery was made by Mr. Turville Petre in 1925 when excavating a cave on the western shores of Lake Galilee, deep in a Mousterian stratum he found the front part of a skull showing Neanderthal characteristics, but also certain other traits which

raised a suspicion that the Neanderthals of Palestine were racially different from their contemporaries of Europe. In 1928, Miss Garrod, while excavating a cave (Shukbah) on the western flanks of the Judean Hill, penetrated a Mousterian stratum and found a tooth and fragment of skull, which, although undoubtedly Neanderthal in their characterisation, left the racial problem of the ancient Palestiniens unsolved. In 1929, Miss Garrod began the excavation of a vast cave in the Wady-el-Mughara in the western flank of Mount Carmel, and again reached a Mousterian stratum.

Although fossil traces were again found in that year and in the following (1930), they were insufficient to throw light on racial characterisation. In 1931, however, the search was crowned with a partial success. Mr. McCown, a student of the American School of Prehistoric Research—recommended by its director, Prof. MacCurdy—joined Miss Garrod, and was placed in charge of the excavation of an adjacent rock-shelter. In the terrace of this shelter, six feet below its surface and four feet within a Mousterian stratum, he exposed

part of a child's skeleton embedded in hard travertine

The block containing the child was hewn out and sent to the Museum of the Royal College of Surgeons, London, where the encrusting rock was successfully chiselled away from the skeleton by Ernest Smith. The extraction involved three months of delicate manipulation. It was then seen that the child had been buried in a sitting posture, heels under the buttocks, back flexed, and head thrust down on the breast. The child had been about four years of age and a little more than three feet in stature, being of slender build. Unfortunately, the face had been smashed after burial and the teeth were found scattered near the skull. The teeth left no doubt as to the racial nature of the child, they had the characteristic Neanderthalian traits. So, too, had the temporal bones. The frontal bone was damaged, but the hinder part of the skull—the part missing in the Galilee skull—was intact and well preserved.

Mr. McCown joined Sir Arthur Keith in January of the present year to complete an investigation of the anatomical details and draw up a report. The hinder part of the child's head differed altogether in its conformation from any Neanderthal skull so far discovered. The cerebellar lobes were set

widely apart, so that when the skull is viewed from behind there is a pronounced lateral fullness or bulge—as in the skulls of young anthropoid apes. There were also certain features which recalled modern rather than Neanderthal man. It became important to remove from the interior of the skull—its walls are only 3 mm in thickness—the hard mass of rock which filled it. This was successfully done by Mr. McCown and a cast was taken of the interior, and thus an exact reproduction of the shape of the brain was obtained. The position of the cerebellar lobes and of the overlying occipital lobes are quite different from the arrangement of parts seen in any known race of mankind.

It therefore became more than ever important that the adult form of the Neanderthal Palestinians should be discovered. The expedition for the present year was timed to set out at the end of March, but owing to Miss Garrod's illness, Mr. McCown had to return alone to resume the excavation of the rock-shelter at Mount Carmel. The cablegram just received announces his success, and justifies the assumption that he is now in a position to determine the racial characteristics of the Neanderthal Palestinians. The stratum at the rock-shelter represents upper or later Mousterian deposits.

### Obituary

SIR PATRICK GEDDES

SIR PATRICK GEDDES died at the Collège des Écossais, Montpellier, on Sunday, April 17, at seventy-seven years of age, but still as full of ideas and enthusiasms as a young man. He was born in Perth in 1854, the son of Capt. Alexander Geddes, of the Black Watch, and he retained throughout life his feeling for the Highlands and their memories and survivals of the days before industrialism. Inspired by Darwin's work, he came to study under Huxley, but his primary interest was in the application of Darwinian ideas to the problems of human society, and he increasingly turned to the ideas of Lamarck, Herbert Spencer, and Auguste Comte, and realised his kinship of thought with Bergson. His thoughts were turned in this direction partly through a threat of blindness which, while he was carrying out research in Mexico, made microscope work impossible and forced him to live in a darkened room. Like Weismann in similar circumstances, he turned to thought and its graphical expression in highly suggestive notation systems.

In biology, Geddes was deeply concerned with ideas of metabolic tides in the organism, and saw plants, animals, and men as incarnations of vital activity fitting the expression of inner needs and urges into the frame of an outer environment that their activity was ever altering. Applications of this point of view to society led him to become the inspiration of the Sociological Society, the apostle of regional and town planning, the friend and counsellor of Herbertson in his geographical efforts at Oxford, the planner of the University of Jerusalem, a suggestive psychologist, and, above all, an

interpreter quick to seize important points in the thought of other men and to respond with suggestions of relations that they might not have perceived. For, in a generation bent on analysis, he was ever seeking synthesis and pressing it forward with his overwhelming physical and mental vigour touched by mystical idealism. To try to help fellow-workers to maintain freshness, he first developed the idea of summer schools, which have become such a feature of educational and research efforts, he interested himself in exhibitions, and all but carried through a magnificent scheme in connexion with the Paris Exhibition of 1900, spoiled in the end by a political crisis arising out of the Dreyfus case. He struggled to express and exhibit in his 'Outlook Tower' at Edinburgh his ideas of synthesis, and many a worker has found there, despite its poverty of resources and resulting inadequacies, a stimulus that has never been lost. A large collection of maps and illustrations relating to the evolution of cities was sunk, during the War, on a journey to Madras.

The partnership of Patrick Geddes and J. Arthur Thomson was as picturesque as it was valuable to other thinkers. Their 'Evolution of Sex', their little book on 'Evolution' in the Home University Library, and their recent instalment of a large work, were all efforts to express a much-needed point of view. In his other partnership, with Victor Branford, Geddes sought in a series of books and articles to give a synthetic view of social evolution. But publication and matters of personal fame in scientific work were always secondary to the desire to help men to understand their environments and

adjust them in such a way as to meet the need, not for immediate gain so much as for an enduring advance from which future generations might gain enhanced opportunities of expression of the best aspects of their personalities. His civic improvements at Edinburgh, his betterment of Indian cities, his efforts for residential halls for British students in French universities with the view of international understanding, and, perhaps most intimately of all, his gardens, were all the expression of the idealism that was the dominant note in a noble character.

#### DR L. A. BAUER

DR LOUIS AGRICOLA BAUER, who was killed on April 12, by falling from a window of his flat in Washington, was probably the best-known authority on terrestrial magnetism in the world. Born in Cincinnati, on Jan. 26, 1865, he was educated at the university there, and in Berlin. From 1887 until 1892 he was astronomer and magnetic computer in the U.S. Coast and Geodetic Survey, and in 1895-96 was an assistant to Michelson at Chicago. There he founded the journal *Terrestrial Magnetism* (the words *and Atmospheric Electricity* being added to the title in 1898), this was then, and still is, the only periodical expressly devoted to the subject. He conducted the journal for many years on his own financial responsibility, occasionally assisted by grants.

In 1896, Dr. Bauer began a magnetic survey of Maryland, under the State geologist—this was the only State magnetic survey that had been undertaken for many years, he continued the survey during two or three summer vacations, and published a very interesting historical account of terrestrial magnetic observation in his first report on the Survey. In 1897 he became assistant professor of mathematics and mathematical physics at Cincinnati. His enthusiasm for terrestrial magnetism, and his energetic pursuit of magnetic work, aroused renewed interest in the subject in the United States, and in 1899 he rejoined the Coast and Geodetic Survey as chief of the newly founded Division of Terrestrial Magnetism. There he initiated an active policy, planning a magnetic survey of the whole of the United States and its territories elsewhere, and, in connexion therewith, instituting four new magnetic observatories, at Cheltenham in Maryland, Baldwin in Kansas, Sitka in Alaska, and Honolulu in Hawaii. He also greatly developed the magnetic work of the ships of the Coast and Geodetic Survey. Though he did not long remain in his new office, his influence on the work of the Coast and Geodetic Survey has been lasting, and the Survey is now one of the most active national organisations undertaking magnetic observatory and survey work.

Bauer's ambitions for his chosen science did not stop short at national frontiers, however, he saw that the science needed a world magnetic survey, and that, on account of the irregular and incalculable course of the secular variation, this survey must be renewed every generation, unless important

data are to be for ever lost. He saw also that this could not be achieved by national organisations, so many countries being scientifically backward, while many parts of the oceans had long remained unsurveyed. He therefore drew up a plan for a research department of terrestrial magnetism, which should fill up what was lacking in the efforts made by other magnetic organisations, as regards the world survey, and also do everything possible in other ways to advance the science. His plans led to the formation of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington, in 1904, he became the first director, and held the office until he retired through ill-health, in 1930. Under his energetic direction, and with the aid of a devoted staff that he gathered round him, the Department has done a great work for terrestrial magnetism and atmospheric electricity. Perhaps its most important work was done by its two survey ships, first the *Galilee*, and later the non-magnetic ship *Carnegie* (unhappily destroyed, with the loss of its commander, Capt. Ault, in 1929, at Apia, Samoa). Much land magnetic surveying was also done, either directly or by aid given to other bodies. Later the Department instituted two magnetic observatories, at Watheroo in Western Australia and Huancayo in Peru, to mitigate the pressing need for more magnetic observatories in the southern hemisphere. A valuable feature of the ocean survey work was the promptness of publication of the results, which enabled the various national ocean magnetic charts to be greatly improved in many respects. In many other directions also the Department carried out important work, which is still continuing and developing.

In his attempts to elucidate the theoretical aspects of the science Bauer was less successful, but it is well known that the subject is a particularly intractable one. His organising work, and its valuable and permanent results, will assure him a lasting and distinguished place in the roll of benefactors to the science, and his services to it were widely recognised in his lifetime, particularly by his election, in 1927, to the presidency of the international organisation for terrestrial magnetism, under the International Union for Geodesy and Geophysics.

S. C.

WE regret to announce the following deaths

Mr B. A. Behrend, consulting engineer to the Westinghouse Electric and Manufacturing Co., Boston, Mass., a distinguished American engineer interested particularly in alternating current phenomena, on March 25, aged fifty-six years.

Sir David Drummond, C.B.E., eminent professor of medicine at the University of Durham College of Medicine, past president of the British Medical Association, a well-known specialist in diseases of the brain, on April 27, aged seventy-nine years.

Dr Victoria Hazlitt, lecturer in psychology, Bedford College, University of London, for some years secretary of the Committee for Research in Education of the British Psychological Society, on April 19.

## News and Views

## Oldoway Man

IN the correspondence columns of the present issue (p. 721) Dr L S B Leakey replies to the criticisms of the conclusions at which he himself and his colleagues have arrived as to the antiquity of the remains of *Homo sapiens* from the Oldoway beds in East Africa. In effect, he agrees with Messrs Forster Cooper and Watson that it is unlikely that the Oldoway skeleton would have been found in a state of complete articulation and in its contracted position had it been deposited by natural means in the situation in which it was found. It will be remembered that others have felt this a difficulty, notably a writer in *L'Anthropologie*, to whose comment we have already directed attention on a previous occasion (see NATURE, April 23, p. 607). Dr Leakey, however, now states that he personally is of the belief that the position of the skeleton is due to burial, but a burial contemporary with and not subsequent to the deposition of Bed No. 2, in which it was found, Bed No. 3 being laid down after the burial had taken place. The complete absence of any trace of intermixture of the yellow deposits of Bed No. 2 and of the red deposits of Bed No. 3, of which Dr Leakey has assured himself by a personal inspection of the actual skeleton, is conclusive. In the event of an ancient burial, such an admixture would be practically inevitable, while of the two alternatives, an ancient and a modern burial, the geological evidence, as interpreted, appears to point beyond question to the former. Strong corroboration is afforded by the fresh evidence now adduced from the fossil beds of the Kavirondo Gulf, where the old Lake beds have yielded Dr Leakey a fauna and a culture sequence similar to Oldoway, but a fragment of human mandible from Kanam carries back *Homo sapiens* to Pre-Chellian, a stage further removed than Oldoway man.

## Physical Research in the University of Melbourne

PROF T H LABY, professor of natural philosophy in the University of Melbourne, is building up an active school of research in the University. He has at the moment eighteen research workers, one-third of whom are full-time workers. Problems in X-rays, heat, and in the propagation of electromagnetic waves are being investigated. Rowland's method of the coincidence in different orders of spectral lines is being applied to the determination of X-ray wave-lengths in terms of wave-lengths in the ultra-violet determined by interferometer methods. A vacuum spectrograph with a Lyle-Merfield grating in which the incident rays make a glancing angle of  $5^\circ$  has been constructed. This work has been delayed by Prof. Laby's recent illness, but tests already made show that the spectrometer is a convenient one, and that a considerable increase in the accuracy of wave-length determinations below 2200 Å, including X-ray wave-lengths, will be possible. Experiments on the reflection of X-rays are being continued. Incidental to them it has been found that the K-radiation of

carbon ( $\lambda = 45 \text{ Å}$ ) can be excited in an X-ray tube without any evidence being found of the presence of accompanying continuous radiation.

IN addition to the work on spectral physics, which alone might be considered sufficient to occupy the attention of a research school, Prof Laby and his collaborators have undertaken investigations on thermal conductivities and the propagation of electromagnetic waves. In view of the uncertainty as to the true value of the thermal conductivities of air and other gases, of their variation with temperature, and similarly of the thermal conductivities of highly purified metals and their temperature variations—our knowledge of the latter seems very indefinite, although there are many theories to account for the supposed facts—experiments to remove some of these uncertainties are being carried out by Hercus, Kannulnik, and others. In the propagation of electromagnetic waves, Martin and Cherry have found evidence that a laterally deviated wave is an important contributory factor to fading. Munro, Huxley, and Higgs, by means of cathode ray direction finders situated at Melbourne and Canberra, have confirmed that atmospherics have their origin in thunderstorms, no other source having been definitely found. The cathode ray direction finder would appear to have considerable value to meteorology and aviation in Australia.

## Huxley Memorial Lecture

MR ALDOUS HUXLEY gave the Huxley Memorial Lecture at the Imperial College of Science on May 4 and took as his subject "T H Huxley as a Man of Letters". The lecture, which is published as a pamphlet by Messrs Macmillan and Co., Ltd., price 1s net, was a careful, thoroughly sound, and highly stimulating treatment of the subject. Mr. Huxley based his account mainly on what his grandfather had said himself about his own methods and ideals in writing, and followed this up by analysing in detail several typical specimens of Huxley's writing. It was well worth doing, and sent one back with increased pleasure to the reading of other passages of that incomparable scientific master of good English. He is everywhere vigorous, true, and terse, and it is useful, though not surprising, to learn from what Mr. Aldous Huxley tells us, that the excellent finished product was not only the result of a clear and able mind but also of long, determined, and painful practice. Huxley talked about it in some detail to several correspondents, telling Hooker in 1860 how he found it constantly more and more difficult to finish things satisfactorily (which meant that his standard was always becoming higher), and apologising to Varigny, his French translator, for the condensed and idiomatic English, "which must present many difficulties to a translator". "Sometimes", he says, "I write an essay half a dozen times before I get it into the proper shape. But"—and here was one of the great secrets of his success—"the fact is that I have a great love and

respect for my native tongue and take great pains to use it properly."

#### Scientific Writings as Literature

WE should, in fact, be inclined to lay the greater stress on Huxley's native taste and effort and on the favourable circumstances of his writings, and less on the detailed features which Mr Aldous Huxley discovers—the balance of phrases, the *cæsura* ending, the Biblical allusions, and so forth. These are by the way. The main thing was having clear ideas and trying always to say them in the fewest and most appropriate words. The true man of science has in this respect an initial advantage over other writers, because he starts with a definite statement about something observed which he wishes to convey to his readers in the most direct and effective way. German writers do not conform to the rule owing to the complication of their tongue, but recently some professors of English in an American university compiled an anthology of extracts from the writings of men of science as a textbook for students in English. Plenty of names will occur to one at once of scientific writers who might be named in the same class as Huxley, though none perhaps so racy and pointed. His own contemporary Tyndall was one of the best. It should also be remembered that these men were living and writing at a time when a great new idea was in the air and inspiring both those who promoted it and those who were on the defensive to special mental gymnastics. No one can read Huxley without enjoying the bracing atmosphere of controversy in which he worked. He was always stripped and putting the last ounce into his fencing. For this both he and we have largely to thank the doctrine of evolution. We are not so controversial at the present day, or at any rate our controversies have not the same all-pervading and stimulating effect.

#### Manson Medal for Tropical Medical Research

THE Manson medal for tropical medical research, given triennially by the Royal Society of Tropical Medicine and Hygiene, has this year been awarded to Dr. Theobald Smith. In association with Kilborne in 1893, Theobald Smith showed that red-water fever in cattle is transmitted by ticks, and at the same time demonstrated the passage of infection through the ova of one generation of ticks to the next. This discovery proved that a protozoal parasite of mammals could be disseminated by the bite of a blood-sucking arthropod. Probably because Theobald Smith was dealing with a cattle rather than a human disease, this great event in the history of medicine received scant recognition, though it preceded the better-known work of Bruce on the transmission of sleeping sickness and that of Ross on malaria. Indeed, Theobald Smith was the first to transfer the insect transmission theory of protozoal disease from the realms of hypothesis to those of established fact. In 1904, Theobald Smith reported anaphylactic symptoms in dogs and rabbits, and, in a letter to Ehrlich, wrote the original description of the classical anaphylactic shock in guinea-pigs often known as the Theobald Smith phenomenon. In 1907 he proved that it was possible to immunise

guinea-pigs actively by the injections of a balanced mixture of diphtheria toxin and antitoxin, and two years later suggested further investigations of the method with the view of its ultimate application to human beings, thus anticipating Von Behring and Park's work by several years. The previous recipients of the Manson medal have been Sir David Bruce (1933), Senator Ettore Machiavava (1926), and Sir Ronald Ross (1929).

#### Gravitation and Electrodynamics

IN the last of his Rhodes lectures delivered at Oxford a year ago, Prof. A. Einstein pointed out that a defect in the original form of the general theory of relativity was that the electromagnetic field was not expressed by means of the metric of the space-time continuum as was gravitation. By introducing a modified form of the Riemann geometry admitting of distant parallelism, Prof. Einstein obtained field equations which he hoped would remedy this defect. From his Rouse Ball lecture at Cambridge on May 5, it appears that this method of approach has been unsuccessful. Prof. Einstein has reverted to a mathematical technique introduced by Kaluza, and has succeeded in defining a vector with four or five components in space of one less dimension. Introducing parallel displacement, a five-component vector is projected repeatedly on to a four-dimensional plane, giving rise to a curve, the properties of which provide the relationship required. In this way the extra term required to account for the phenomena of electrodynamics is obtained. The method resembles that used in building up the general theory of relativity.

#### Twenty-one Years of Radio Communication

WE congratulate the *Wireless World* on the completion of its twenty-first birthday, which is commemorated in the issue of April 27. For its first two years, the journal was known as the *Marconigraph*, but as the number of amateur enthusiasts was rapidly increasing, it changed its title to the more comprehensive one of the *Wireless World*. So far back as 1914, we find from its pages that the late Mr Campbell Swinton practically predicted the ultimate possibilities of wireless and indicated that at no distant future we would have broadcasting. The War gave a great impetus to the development of radio. After the War, the *Wireless World* took a leading part in the movement for granting amateur licenses and in encouraging the 'Dutch concerts' and the transmissions from Writtle—the forerunners of wireless telephony and broadcasting. It organised communication tests between amateurs in Great Britain and America with the object of finding out whether it would be possible to bridge the Atlantic on short waves. The success of these tests led to intensive research and the discovery that these waves were ideal for distant communication. It also played a foremost part in connexion with Empire broadcasting, and helped to overcome the bitter opposition to the scheme which lasted for several years. The progress made by radio communication during the last twenty-one years is marvellous. There seems no reason to doubt that equally rapid progress will be made for

many years to come. Methods of communication which twenty-one years ago stretched our imagination to the utmost are now commonplace practice. We congratulate Mr H S Pocock, the editor, on the excellent work he has done.

#### University of the Witwatersrand Library

LAST Christmas Eve, a fire took place in the main block of the University of the Witwatersrand. As a result, very considerable damage was done. The main Library was completely destroyed, as were also the priceless Gubbins collection and the Law Library, which are, naturally, irreplaceable. Through the co-operation of the British Association and of other bodies, many replacements of lost and damaged books have been made, but in order to broaden the basis of the appeal, a meeting was held on May 9, in the council room of the Royal Empire Society, presided over by the Earl of Athlone, himself an honorary graduate of the University, the degree of LL D having been conferred upon him when he was the Governor-General of the Union of South Africa, during the visit of the British Association to Johannesburg in 1929. In the course of his introductory remarks, Lord Athlone traced the development of university education in South Africa, and pointed out that the University of the Witwatersrand only received its charter of incorporation ten years ago. In 1925, H R H the Prince of Wales formally opened the new buildings, which occupy a magnificent site on the outskirts of the city. General Smuts was the first honorary graduate. The progress made has been remarkable, and there are now about two thousand students taking the regular courses. It was therefore a tragedy that the 'soul' of the University had been destroyed through the fire.

As a result of the meeting, which was addressed by Dr W Cullen, Mr J G Gubbins, Prof. A P Newton, Sir Frank Heath, and others, a strong and representative committee, upon which Lord Athlone consented to serve, was formed to co-ordinate British efforts for restoring the library of the University. The loss includes the collection of manuscripts, books, and prints presented by Mr Gubbins, the Hoernlé anthropological collection, in addition to all scientific journals and the departmental libraries of classics, English, Afrikaans, German, French, history, mathematics, geography, economics, and education. If the appeal for funds is successful, it is proposed to build a fireproof library, as a separate building, at an estimated cost of £60,000, a large part of which will probably be raised from people who live, or have lived, in South Africa. The chief task of the appeal committee will be, therefore, to procure books and other works to restock the library. It is, of course, impossible to replace the original documents destroyed by the fire, but it is hoped that other collections of a like kind will be forthcoming as the needs of the new library become known and the opportunity which it affords of representing every phase of South African life and culture is realised. Gifts of sets of journals and works of reference will also be gratefully accepted. All communications relating to such gifts should be sent to Dr W Cullen, 4 Broad Street Place, London, E C 2.

#### Plastic Deformation of Metals

DR. F KÖRBER, director of the Kaiser Wilhelm-Institut für Eisenforschung, Düsseldorf, delivered the twenty-second annual May lecture of the Institute of Metals in London on May 11, on "The Plastic Deformation of Metals". Basing his remarks on the results of a series of investigations conducted at Düsseldorf during recent years, Dr Körber dealt with the stress relationships and also with the course of the flow of the material during the most important of the mechanical shaping processes. Discussions were entered into on the conditions requisite for the commencement of plastic flow and also on the possibility of drawing conclusions from the resulting flow phenomena as to the distribution of stress in the material at the inception of deformation. The disturbances in the material in consequence of the more marked deformations in drawing, extrusion, and rolling were traced by a suitable method of investigation. The results were compared with the deformation structures obtained by X-ray methods. The knowledge of the deformation processes so obtained enabled conclusions to be drawn as to the energy or power used in the shaping operations. An exact analysis of the course of deformation in the transition zone led to estimates of the internal losses during the alterations in form. Quantitative treatment of the stress relationships which occurred in the zone of deformation is possible in so far as the pressure created at the surface of contact between the tool and the material is known by actual measurements. From the results of determinations along the roll-gap of the pressure between the rolls and the stock being rolled, a complete quantitative presentation of the distribution of stress in the transition zone between the rolls has been formulated.

#### Electrification of Ulster

IN the *Asea Journal* for February an account is given of the electricity distribution scheme in Northern Ireland. The Irish Free State has built a large water power station on the River Shannon, on the west coast. In Northern Ireland (Ulster), there is also a considerable amount of water power available in the River Bann, which drains a large area round Lough Neagh. A scheme was recently under consideration to build a water power station on this river, but as the question is intimately connected with a land drainage scheme to be carried out by the Government, this scheme has been temporarily suspended. A steam power station has been built in Larne, on the east coast, not far from Belfast. From this station, a 33-kilovolt main transmission line has been taken over the country, through the towns of Ballyclare and Ballymena, with the view of future connexion with the River Bann. The steam power station at Larne has two turbo sets, each of 1750-kilowatt output, and a space has been reserved for one of double the size. In this way the load will be built up gradually, so that when the water power station with its comparatively high initial cost is completed, it will be possible to load it profitably from the start. The electric power will be mainly used by the linen industry, which has long flourished in Ireland. There are also paper mills and cement works in the

district, and numerous small townships. A local company in Larne owns the power station and a Belfast company the overhead distribution system.

#### Atmospheric Effects and the Andean Eruptions

WHEN a solar halo and sun pillar were observed in London a few days after the recent volcanic outbreaks in the Andes, the question of a connexion between the two phenomena was raised. There was no serious case to be made out for any such connexion, in view of the enormous distance that separates Great Britain from the scene of the eruption, and the incredible wind velocity that would have been necessary to bring volcanic dust in such a short time. Moreover, optical phenomena of this kind are known to be due to ice crystals at great heights and not to dust. The more rational question of ultimate meteorological effects in the northern hemisphere is discussed in a recent bulletin from Science Service, Washington, D C. We are reminded that after the explosion of the East Indian volcano Krakatoa in 1883, volcanic dust drifted entirely round the earth, and that the remarkable red sunsets that occurred for several years after can reasonably be attributed to the presence of this dust, for the selective absorption effects of dust upon the constituent colours of the light of the sun is proved at almost every fine sunset in industrial regions. Prof. W. J. Humphreys, of the U.S.A. Weather Bureau, has expressed the opinion that it is only on the supposition that the ash has ascended in large quantities above the level of the highest clouds that it may be expected to cross over to the northern hemisphere, if confined to lower layers, it may perform long journeys in the atmospheric circulation of the southern hemisphere but will tend to be entangled by condensing cloud particles and be brought to the earth by rain. Apart from sunset effects, the probable influence of dust at very high levels upon the weather through weakening of the solar radiation is difficult to estimate, owing to the complexity of the reactions likely to be set up.

#### Funerary Offerings from Ancient Mexico

A tomb deposit described as second only in intrinsic value to the recently discovered treasure of Monte Alban, we learn from a recent Science Service bulletin, has been discovered at Texmelincan, in the State of Guerrero, one hundred and twenty miles south of Mexico City. The tomb is situated in an area covered with mounds concealing buildings and other remains. The objects in the tomb have now been deposited in the Department of Archaeology, Mexico City. Among them the most notable is a disc of gold, eight inches in diameter, with a hole in the centre. On it are engraved two of the characteristic feathered serpents, intertwined, and with the head of an armed warrior protruding from the jaws of each. Two belts, two feet long and three inches wide, are covered with a thin sheeting of beaten gold. There were also found large gold ear-rings, a necklace of thirty-two hollow gold beads and one of seventy-one unusually fine carved jade beads, three necklaces of shell and stone beads, copper bells, and obsidian ear-rings painted red. Some finely polished pottery vessels suggest a Toltec

origin. The nearest important city site, it is pointed out, is Xochicalco, which is noted for its 'Toltec Maya' style.

#### The Rebuilding of Napier and Hastings

The New Zealand correspondent of the *Times*, in the issue for May 5, has given an interesting account of the rebuilding and repair of the towns damaged by the Hawkes Bay earthquake of Feb. 3, 1931. The total loss was estimated at about six million pounds. One-quarter of this amount was provided by the Government, and public subscriptions added nearly £350,000. In Napier, nearly the whole of the business quarter was destroyed. The work of reconstruction includes the widening and replanning of many streets, the laying down of about 20 miles of main sewers, and the provision of new artesian wells or the repair of old ones sufficient to give a supply of four million gallons daily. An unexpected gain from the earthquake is an extensive area of new land. Before the earthquake, plans had been made to reclaim certain shallow parts of the harbour. This work is now unnecessary, as the earthquake raised the level of the land by five or six feet. About 7000 acres of the new land, it is proposed, will be converted into farming land, and the long marine parade will be widened and beautified.

#### Announcements

SIR ARTHUR KEITH will deliver the Stephen Paget memorial lecture at the annual general meeting of the Research Defence Society, which is to be held on Wednesday, June 15, at 3 P.M., in the lecture hall of the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1.

APPLICATIONS for grants from the Research Fund of the Chemical Society must be made by June 1 on a special form obtainable from the Assistant Secretary, Chemical Society, Burlington House, W.1. Attention is directed to the fact that the income derived from the donation of the Goldsmiths Company is more or less especially devoted to research in inorganic and metallurgical chemistry, and that from the Perkin Memorial Fund to investigations relating to problems connected with the coal-tar and allied industries.

At the annual general meeting of the Challenger Society held on April 27, a resolution to the following effect was carried unanimously. "That a sum of money, provisionally put at £25, to be modified at the discretion of the Committee, should be devoted to the assistance of a desirable student (or students) to enable him (or them) to work at Plymouth (or other Marine Biological Station). Preference to be given to members of the Society, and the selection to be in the hands of the Committee."

THE following appointments have recently been made by the Secretary of State for the Colonies in the Colonial agricultural and forest services. Mr. E. Ballard, to be Government entomologist, Palestine; Mr. E. D. Hill and Mr. W. R. Hudson, inspectors of plants and produce, Gold Coast, to be senior inspectors, Mr. R. R. Staples, agricultural economist, Tanganyika Territory, to be pasture research officer,

Tanganyika Territory, Mr C. G. Trapnell, to be ecologist, Northern Rhodesia, Mr. H. E. Desch, formerly assistant conservator of forests, Nigeria, to be forest research officer (wood technologist), Federated Malay States.

THE Council of the Institution of Civil Engineers has made the following awards in respect of papers read and discussed at the ordinary meetings during session 1931-32. Telford Gold Medals to Dr C. F. Jenkin, emeritus professor of engineering science in the University of Oxford, and to Sir Bernard D'O Darley, of Bahawalpur, India; Stephenson Gold Medal to Mr B. G. White (London), a Telford premium jointly to Mr H. C. Whitehead (Birmingham) and Mr F. R. O'Shaughnessy (Birmingham); Telford premiums to Mr Raymond Carpmal (London), Mr. H. J. Deane (London), Mr John Goodman (Skipton), a Manby premium jointly to Mr W. F. Stanton (Bishops Castle) and Mr A. G. Le Clercq (Walton-on-Thames), a Trevithick premium to Mr. W. C. Ash (Vizagapatam, India).

THE Council of the Institution of Electrical Engineers has made the following awards of premiums for papers read during the session 1931-32, or accepted for publication. Institution premium to Mr. J. Bruce, Ayrton premium to Mr F. Lydall, Fahie premium to Messrs H. Kingsbury and R. A. Goodman, John Hopkinson premium to Mr H. W. Clothier; Kelvin premium to Prof W. M. Thornton and Dr W. G. Thompson, Paris premium to Messrs E. W. Dickinson and H. W. Grummitt, extra premiums to Messrs H. Blades and A. C. MacQueen, Messrs R. O. Kapp and C. G. Carrothers, Dr F. Luschen, Messrs H. Pearce and T. T. Evans, Mr E. A. Watson, Major E. H. E. Woodward, and Mr W. A. Carne. Wireless Section premiums. Duddell premium to Mr T. L. Eckersley, extra premiums to Mr B. S. Gossling, Messrs J. A. Ratchiffe, L. G. Vedy and A. F. Wilkins. Meter and Instrument Section premiums. Silvanus Thompson premium to Prof J. T. MacGregor-Morris and Mr H. Wright, an extra premium to Mr S. H. C. Morton.

Two awards of the Gold Medal of the Institution of Mining and Metallurgy, the highest distinction in its power to confer, have been made by the Council: (a) Sir Harold Carpenter, in recognition of his eminent services in the advancement of metallurgical science and technology; (b) Dr Thomas A. Rickard, in recognition of his services in the general advancement of mining engineering, with special reference to his contributions to technical and historical literature. The following awards have also been made. The Consolidated Gold Fields of South Africa, Ltd., Gold Medal to Mr P. J. Crowle for his investigations on ground movement and methods of support in deep mines (Kolar Gold Fields), The Consolidated Gold Fields of South Africa, Ltd., premium of forty guineas to Prof Bernard W. Holman for his work on flotation reagents, the William Frecheville Student's Prize of ten guineas to Mr Gilbert F. Hatch for his paper on "Check Sampling of Diamond Drill Holes at the Trepcia Mines, Jugoslavia".

No 3263, Vol. 129]

THE office of the High Commissioner for India, India House, Aldwych, is about to publish, in two volumes, "A Manual on the Commercial Timbers of British India", by R. S. Pearson and Prof. H. P. Brown. Descriptions will be given of each family and genus, while under species each timber will be dealt with in detail, commencing with nomenclature and references and followed in order by information on distribution, supplies, a full description of the structure of the timber, mechanical and seasoning properties, durability, working qualities, and present and prospective uses.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A headmaster of the Junior Technical School, Stoke-on-Trent.—The Director of Education, Education Offices, Town Hall, Hanley, Stoke-on-Trent (May 16). A lecturer in the Department of Commerce of the Leicester College of Technology.—The Registrar, College of Technology, Leicester (May 18). A head of the Junior Day Technical (Engineering) School of Handsworth Technical College.—The Chief Education Officer, Higher Education Department, Education Office, Margaret Street, Birmingham (May 23). A demonstrator of physiology at the London (Royal Free Hospital) School of Medicine for Women.—The Warden and Secretary, 8 Hunter Street, W.C.1 (May 25). A head of the Chemistry Department and a lecturer in physics and subsidiary chemistry at the Kingston-upon-Hull Municipal Technical College.—The Director of Education, Education Offices, Guildhall, Hull (May 28). A lecturer in mechanical engineering at Armstrong College.—The Registrar, Armstrong College, Newcastle-upon-Tyne (May 28). A lecturer in mechanical engineering at the Camborne Technical School.—The Principal, Technical School, Camborne (May 31). A Morna Macleod research student in biochemistry at the Lister Institute of Preventive Medicine.—The Secretary, Lister Institute, Chelsea Bridge Road, S.W.1 (June 1). A resident assistant pathologist at the Royal Free Hospital and London (R.F.H.) ### Photochemistry of Vitamins A, B, C, D

THE photochemistry of the vitamins has been studied with the help of a large quartz monochromator. The solutions to be irradiated were enclosed between quartz windows in a rectangular slot cut in a small brass block. The section of the cell corresponded with the dimensions of the rectangular image formed by the curved slit of the monochromator, so that the whole of the solution was irradiated. The cell was filled and emptied with a hypodermic syringe, and was arranged so that the solutions could be handled in the absence of oxygen. Stirring was effected by two steel shot operated by a magnet.

The procedure was to study the absorption spectrum of the substance, and then to irradiate it with an intense beam of light of similar wave-length to that of an absorption band selected after consideration of the spectroscopic data. This procedure usually destroyed the electronic system producing the band, and often led to the development of new bands. When applied to a suitable pre-vitamin, monochromatic irradiation with light of the correct wave-length produces maximum yields of the vitamin, on the other hand, when the destruction by irradiation of the biological activity of a vitamin is effected by the elimination of an absorption band, the activity can be linked up conclusively with the presence of the band. The principal results obtained up to the present are set out below.

**Vitamin A**—The absorption spectrum of  $\beta$ -carotene (supplied by Dr Thomas Moore of the Nutrition Laboratory) was found to contain a weak band at 2700 Å, in addition to the well-known bands in the visible. Since this band was thought to be of peculiar importance, a solution of carotene in cyclohexane was irradiated in an atmosphere of nitrogen by the mercury line 2650. After a few hours, a strong band appeared at a wave-length corresponding closely with that of the band at 3280, which is already widely recognised as characteristic of vitamin A. Further, the solution gave a blue coloration with antimony trichloride in chloroform. Biological experiments, which will occupy perhaps a month, have already been begun in order to determine the activity of the irradiated solution. If the results of these experiments are in harmony with the spectroscopic evidence, it will appear that a photochemical transformation of carotene into vitamin A has been effected.

The destruction of vitamin A has been effected by irradiation with light of wave-length 3130, whereby the characteristic band at 3280 was eliminated in the course of a few hours.

**Vitamin B<sub>1</sub>**—A specimen of vitamin B<sub>1</sub>, prepared by Jansen and Donath and supplied to us by Mr. Birch of the Nutrition Laboratory, showed three absorption bands at 2600, 2400, and 2100. Irradiation by the mercury line 2537 greatly reduced the intensity of the band at 2600, and destroyed the B<sub>1</sub> activity of the sample, as tested by Mr. Birch's observations of the heart-beats of rats. A specimen of the vitamin which had been deactivated by heating with alkali showed a similar absorption spectrum, in which the band of longest wave-length was again missing. The correlation of the 2600 band with the activity of vitamin B<sub>1</sub> has thus been fully established.

**Vitamin C**—We have not yet been able to examine the absorption spectrum of vitamin C, but have found a strong band (which is affected but little by irradiation) at 2650 Å in hexuronic acid, which Szent-Gyorgyi<sup>1</sup> has identified with this vitamin. We have also examined the absorption spectrum of narcotine, which, according to Rygh, is converted into vitamin C by irradiation. In our experiments, no change in the spectrum was produced by irradiation with light corresponding with the wave-length of the bands at 3000 and 2850 Å, but irradiation with light covering the band at 2400 produced a complete change in the spectrum, which after irradiation consisted of a single band at 2900 Å. A comparison of the spectrum of a concentrate of vitamin C with those of hexuronic acid and of narcotine, before and after irradiation, should go far towards settling the problem of identifying the vitamin with these substances.

**Vitamin D**—The conversion of ergosterol into calciferol by irradiation is rendered difficult by the overlapping of their absorption bands, since the five narrow bands of ergosterol are almost covered by a wide calciferol band of shorter wave-length. The wave-length of the mercury line at 3130 was found to

FIG. 1.—Spectra of vitamins (positive, showing dark absorption bands)  
1 Carotene 2 Carotene after irradiation with  $\lambda$ 2537 3 Vitamin B<sub>1</sub> 4 Vitamin B<sub>1</sub> after irradiation with  $\lambda$ 2537 5 Vitamin B<sub>1</sub> after heating with alkali

be too long to convert ergosterol into calciferol even after irradiating for several hours in the absence of oxygen, but the 2967 line, which corresponds approximately with the longest wave-length of the ergosterol bands, produced a strong absorption in the calciferol region after only two hours' irradiation. On the other hand, calciferol was destroyed completely by irradiation for one hour with the mercury lines at 2650 or 2537, with a very slow destruction (which may be attributed to the great width of the calciferol band) when irradiated by the line at 3130. A maximum yield of calciferol is therefore to be expected when light of wave-lengths less than about 2800 is cut out, in agreement with the methods of Reerink and van Wijk and of Askew *et al.* In order to obtain further information, it is proposed to work out the kinetics of these transformations and to determine the quantum efficiencies of the two photochemical processes for light of various wave-lengths, the spectroscopic evidence is, however, already sufficient to indicate that the conversion of ergosterol into calciferol depends on the migration of a double bond to a position in which its influence on the other double bonds is greatly enhanced.

A fuller account of these experiments will be published later, but it is already clear that irradiation

with monochromatic light has very great advantages (as compared with the use of filters) for photochemical experiments in the ultra-violet, especially in the ease and certainty with which an absorbing group can be eliminated from a complex organic molecule by irradiation with light of related frequency. The value of the spectroscopic diagnosis of the structure of the absorbing centres in complex organic compounds will also be rendered much more complete and certain when it is possible to carry out the examination at the temperature of liquid hydrogen, preparations for which are already in progress.

The experiments described above were only possible as a result of the generous co-operation of our biological colleagues in Cambridge and of the Medical Research Council. In particular, we wish to acknowledge our indebtedness to Sir Frederick Gowland Hopkins, Prof J B S Haldane, Mr N W. Pime, and Dr B Woolf of the Sir John Dunn Laboratory of Biochemistry, to Dr L J Harris, Dr T Moore, and Mr T. W. Birch of the Nutrition Laboratory, and to Dr Bourdillon and his collaborators at Mount Vernon.

### Properties and Structures of Crystalline Vitamins

THE absorption spectra of crystals of ergosterol and calciferol are the same as those of their solutions but for a slight alteration of wave-lengths. The changes produced in solution by irradiation in monochromatic ultra-violet light can also be produced in crystals. They can be observed by the progressive alteration from anisotropic to isotropic material in a polarising microscope. Ergosterol is transformed presumably to calciferol in light of 2967 Å, but scarcely at all in 3650, 3130, and 2537 Å. Calciferol, on the other hand, is stable at 3650 and 2537 Å, but destroyed in 3130 Å. This differs from the behaviour of solutions partly on account of the greater absorption and the formation of protecting layers on the surface of the crystals.

X-ray analysis of crystalline vitamins reveals only the general size and shape of the molecule and is not sensitive to activation. Further work on pyrociferol, suprasterol, and also on cholesterol, cholic acid, and pregnandiol, has shown the essential correctness of my previous suggestions on sterol structure<sup>1</sup>. It is clear that the usually accepted sterol structure must be considerably modified. The crystals of vitamin B<sub>1</sub> show a large, flat cell, and that and their strong negative birefringence point to ring molecules. The same is true of hexuronic acid. The crystals of β-carotene and the related α-crocin do not show the long spacings expected from the constitution of these bodies, but further work is necessary to elucidate their structure.

### The Oldoway Human Skeleton

IN NATURE of Feb 27, p 312, Messrs Forster Cooper and Watson set out the reasons by which they are "forced to the conclusion that the Oldoway man reached the position in which he was found by an artificial and probably a relatively recent burial". Among the reasons which they adduce for this conclusion is the fact that the "skeleton, which is of modern type, with filed teeth, was found completely articulated down even to the phalanges, and in a position of extraordinary contraction". As field palaeontologists, they regard the possibility of a

skeleton getting into the deposits in such a state by *natural means* as so unlikely, that they find it hard to believe that the skeleton was contemporary with the deposits in which it lay.

In our letter in NATURE of Oct 24, 1931, p 724, we stated our conclusion "There is no possible doubt that the human skeleton came from Bed No 2 and not from Bed No 4", and we also stated that "Beds Nos 3 and 4 overlie Bed No 2 conformably", but we made no statement that the skeleton was deposited in Bed No 2 without artificial aid.

Personally, I am quite in agreement with Messrs. Forster Cooper and Watson that a *complete articulated human skeleton in the contracted position* is not likely to become buried in a lake deposit by natural agencies, but I have never claimed that that happened with the Oldoway skeleton, although I am aware that Prof Reck did formerly make such a claim.

I am, however, quite satisfied, after examining all the evidence, that Bed No 3 at Oldoway, with its 50 per cent extinct fauna, was laid down after the skeleton became embedded in Bed No. 2, and that the skeleton was certainly not a *subsequent* burial into the deposits. My own personal belief is that contemporary man, living on the edge of the then existing Oldoway lake, buried the skeleton into the muddy, clayey edge of the lake whilst Bed No 2 was in process of being deposited, for Bed No 2 is essentially a shallow water deposit at the place where the skeleton was found. Bed No 3, which is of a brilliant red colour and of quite a different texture, was then deposited above it.

It would take too much space to set out here all the geological and other evidence which shows that the skeleton was already in Bed No 2 before Bed No 3 was laid down, but I may perhaps summarise some of the chief reasons, as follows.

Bed No 2, which contained the skeleton, is of a yellow colour, and the skeleton lay in its topmost levels. Immediately over it lies Bed No 3, which is red in colour and of a quite different texture.

The position of the skeleton was such that unless it had been buried into the deposits within the last few years (at most fifty) any supposed grave-digging into Bed No 2 must also have affected Bed No 3, and it thus follows that, unless the skeleton was a burial of the past very few years, the refilling of the grave must have resulted in an admixture of red and yellow material around the body.

I was lucky enough personally to examine the skeleton at Munich while it was still intact in its original matrix, and could detect no trace whatever of such admixture, or of disturbance.

The bones of the skeleton, while not so heavily mineralised as those from Bed No. 3 or even Bed No 1, are, so far as I know, every bit as mineralised as most of the bones from Bed No 2 itself. This less complete mineralisation is presumably due to the varying nature of the deposits.

I have personally examined the so-called 'filing' of the teeth of the Oldoway man on the original specimen at Munich, and this 'filing' has no resemblance to any filing done by native tribes to-day, and it is, to my mind, exceedingly doubtful if it can be called filing at all.

I hope that Messrs Watson and Forster Cooper will have been satisfied by this statement of mine, incomplete though it is, but I should like to give them still further evidence in support of the genuineness of the antiquity of *Homo sapiens* in East Africa.

During the past six weeks, I have been carrying out investigations on the north-east shore of Victoria Nyanza, at the well-known fossil beds in the region of Kendu and Homo on the south side of the Kavirondo Gulf.

My results there have far and away exceeded my expectations, and amply corroborate the conclusions we came to at Oldoway. A series of old lake beds was examined which yielded a fauna and a culture sequence similar to that of the Oldoway Beds Nos 1 to 4. The beds were found to contain teeth of a giant *Demotherium* of the same type as that from Bed No 1 at Oldoway, in association with tools of Pre-Chellean type exactly as at Oldoway. This same bed also yielded teeth of an extinct elephant apparently (I have only Zittel available) closely allied to, if not actually a species of, *Tetrabelodon*. The later beds contain *Elephas antiquus* sp., *Hylochoerus* sp., *Hipparion* sp., *Pelorovis* (?), and other animals typical of the higher Oldoway beds, together with tools of the Chellean type.

Actually *in situ* at a place called Kanam, in the same horizon as the Pre-Chellean tools and the *Demotherium*, we found a fragment of a mandible of *Homo sapiens* type, thus putting *Homo sapiens* in East Africa back one stage further than Oldoway man—in fact, in deposits of the same age as Bed No 1 at Oldoway. The horizons which have yielded the Chellean tools have not yielded, unfortunately, human remains actually *in situ*. We have, however, found fragments of the skulls of three different individuals of *Homo sapiens* type completely mineralised and just washed out of the exposures by the rains. They are in the same state of complete mineralisation as the remains of *Elephas antiquus*, *Hipparion*, etc., from the same beds, and I have personally no doubt whatever that they were *in situ* a month or two ago, before the beginning of the present rainy season. These later remains are probably, then, the contemporary of the Oldoway skeleton, and since we have fragments which make up the greater part of the skull cap of one of the individuals, an interesting comparison will be possible later on.

In conclusion, I may record the discovery of teeth, with fragments of upper and lower jaws, of several individuals of a very interesting anthropoid ape in deposits of apparently Miocene age on Rusinga Island. The associated fauna includes creodonts, a small primitive rhinoceros, very numerous remains of a small *Demotherium* about half the size of the Oldoway *Demotherium*, and numerous other unidentified teeth and bones. I hope to be able to make a further communication about this anthropoid shortly.

#### Modification of Light Quanta by Elastic Heat Oscillations in Scattering Media

IN my previous communications<sup>1</sup> I pointed out the existence of a new type of modified radiation produced by scattering of light in liquids and crystals, which may be ascribed to the interaction of light waves and the acoustic oscillations in the medium.

Recent experiments with carbon disulphide and chlorobenzene have fully confirmed the results obtained previously with other liquids. The unmodified and modified components in the case of these liquids are very diffuse. The observed and calculated values of the displacements of components are given in the accompanying table.

|                   | $\Delta\lambda_{\text{obs}}$ in Å | $\Delta\lambda_{\text{calcul}}$ in Å |
|-------------------|-----------------------------------|--------------------------------------|
| Carbon disulphide | 0.049                             | 0.040                                |
| Chlorobenzene     | 0.047                             | 0.042                                |

In Fig 1 microphotometer curves of spectrograms from benzene at scattering angles  $\theta = 90^\circ$  and  $\theta = 135^\circ$

are shown and the unmodified and modified components can be seen quite clearly. The results of the measurements of these spectrograms are given in Table 2 in my previous note<sup>2</sup>.

The appearance of the central unmodified line, which should not be present according to the Brillouin-Mandelstam theory,<sup>3</sup> may possibly be explained by superposition of unresolved modified lines due to

FIG 1

reflections of higher orders. These reflections arise from heat waves of wave-lengths 2, 3, 4, times greater than that which produces the first order reflection with the change of the frequency determined by the equation

$$\Delta\nu = \pm 2\nu_0 \frac{v}{c} \sin \frac{\theta}{2}$$

The modification of frequency produced by reflections of higher orders should be 2, 3, 4, times less than that given by this formula. The superposition of these unresolved modified lines may give rise to the appearance of the broadened central 'unmodified' line. The identity of polarisation of 'unmodified' and two adjacent modified lines<sup>4</sup> is in accordance with this view.

In all liquids as yet investigated, I have been unable to detect any displacement of the scattered line towards the red ( $c = 0.05 \text{ Å}$ ) as was described by Cabannes and Salvaire<sup>5</sup>. I was also unable to find such displacement in the same two liquids (benzene and ethyl alcohol), which were investigated by Cabannes and Salvaire. With my apparatus I could easily detect much smaller displacements than those ( $0.035 \text{ Å}$  and  $0.05 \text{ Å}$ ) observed by these authors.

To make this point clear, Mr Khvostikov and I undertook a careful comparative examination with an echelon grating of light scattered by benzene and by optical glass. It has been shown<sup>6</sup> that optical glass does not produce any noticeable modification in the scattered light. During the whole time of exposure, the spectra produced by benzene and glass were photographed simultaneously side by side on the same photographic plate. It was found that the central component of benzene coincides with the single line (unchanged original line) given by optical glass, and

two modified components of benzene are situated symmetrically on both sides of it

Further investigations were undertaken with styro-  
lene ( $C_8H_8$ ). In this amorphous solid, Cabannes has  
found<sup>7</sup> a displacement towards the red of the scattered  
line similar to that in liquids. With this substance  
also we were unable to confirm the observations of  
Cabannes. In accordance with what would be expected  
from theoretical considerations,<sup>6</sup> neither broadening  
nor displacement of the line scattered by styro-  
lene could be detected.

Recently the experiments on the structure of  
the scattered lines were repeated by Vacher<sup>8</sup> and  
Rafałowski.<sup>9</sup> Using a Fabry and Perot interferometer,  
Vacher was unable to detect the modified lines found  
by me. He could not find any splitting (structure) of  
the scattered line, but only the broadening and the  
displacement towards the red of the original line. Thus  
his results agree with those of Cabannes and Salvaire.

Rafałowski, using a Lummer-Gehrcke plate, also  
was unable to confirm my observations. The modified  
lines observed by me should appear in the spectrum  
half-way between the neighbouring orders of the  
primary line. He found, however, that the spectrum  
of light scattered by benzene differs from that scattered  
by white paper (that is, arc spectrum) only by  
continuous background and by a slight broadening  
of lines.

I repeated, therefore, with a large glass Lummer-  
Gehrcke plate (1 cm  $\times$  4 cm  $\times$  30 cm), the comparative  
examination of light scattered by benzene and by  
optical glass described above, although I believe that  
a Lummer-Gehrcke plate is less suitable for the  
examination of the phenomenon than an echelon  
grating. Owing to overlapping of different orders,  
the structure of the scattered line could not be  
resolved (the distance between neighbouring orders of  
my Lummer-Gehrcke plate is only 0.07 Å at  $\lambda 4358$  Å).  
The photograph showed a continuous blackening in  
the case of benzene, whereas optical glass gave well-  
defined interference fringes.

These results are in agreement with my previous  
experiments with an echelon grating and confirm the  
existence of modified lines of nearly the same intensity  
as the unmodified one, and disagree with Rafałowski's  
observations.

A detailed account of the experiments will be pub-  
lished in the *Zeitschrift für Physik*.

### Isotopic Displacement and Hyperfine Structure

THE analysis of the hyperfine structure of thallium  
and mercury<sup>1</sup> has led to the discovery of a structure  
which is not due to the spin of the nucleus but to a  
displacement of the atomic levels in different isotopes.

Recently, Bartlett<sup>2</sup> has carried out some calcula-  
tions on the order of magnitude of these displacements,  
assuming deviations from the Coulomb law near the  
nucleus, he assumed the potential energy to have a  
constant value  $V_0$  for distances smaller than a certain  
critical radius  $r_m$ , where  $r_m$  may be called the radius  
of the nucleus. His calculations led to an agreement  
as to the order of magnitude of the displacement of

atomic levels with those found experimentally, if  
 $r_m$  was chosen to be equal to  $10^{-12}$  cm and  $\delta r_m$  (for  
different isotopes) of the order of  $10^{-13}$  cm. These  
values are of the same order of magnitude as those  
to which Gamow's theory of the  $\alpha$ -decay led.<sup>3</sup>

However, Bartlett's method of calculation is very  
rough, as he works out the energy of perturbation  
with the help of eigenfunctions of hydrogen-like atoms,  
not taking account of the screening of the nucleus by  
the core electrons. This, of course, would result in a  
considerable over-estimation of the displacement, if  
it were not compensated by the omission of a factor  
 $\sqrt{Z^3/n^3}$  in the coefficient of normalisation. Further-  
more, Bartlett is neglecting relativity corrections,  
which, according to our calculations, are not in-  
appreciable, owing to the fact that the eigenfunctions  
become infinite at the origin.

We have worked out the displacements using eigen-  
functions of the relativistic equation, normalising  
them so as to be asymptotically equal to the Schrod-  
inger eigenfunctions for large values of  $r$ . We find<sup>4</sup>  
that for  $s$ -electrons the electronic density near the  
nucleus becomes

$$\frac{2(1+\rho)\psi^2(0)}{[\Gamma(2\rho+1)]^2} \left(\frac{2Zr}{a_1}\right)^{2\rho-2}$$

where

$$\rho = \sqrt{1-\gamma^2}, \quad \gamma = Za = \frac{2\pi Ze^2}{hc} \sim \frac{Z}{137},$$

$a_1 = \frac{h^2}{4\pi^2 me^2}$  = radius of the Bohr orbit of hydrogen,  
and  $\psi(0)$  the value of the unrelativistic eigenfunction  
in the origin, which has to be worked out numerically  
with the help of the Thomas-Fermi potential.

From this we derive for the displacement  $w$  of an  
 $s$ -term, assuming for the potential inside the nucleus  
 $V_0 = -\frac{Ze^2}{r_m}$

$$w = \frac{8\pi(1+\rho)\psi^2(0)}{[\Gamma(2\rho+1)]^2 hc} \left(\frac{2Z}{a_1}\right)^{2\rho-2} \int_0^{r_m} \left(\frac{Ze^2}{r} - \frac{Ze^2}{r_m}\right) r^{2\rho} dr$$

$$= \frac{8\pi(1+\rho)\psi^2(0)}{[\Gamma(2\rho+1)]^2 (2\rho+1) hc} \left(\frac{2Z}{a_1}\right)^{2\rho-2} Ze^2 r_m^{2\rho} \frac{1}{2\rho}.$$

The relative displacement  $\delta w$  of two isotopes with  
a difference  $\delta r_m$  between the radii of their nuclei  
becomes therefore

$$\delta w = \frac{8\pi(1+\rho)\psi^2(0)}{[\Gamma(2\rho+1)]^2 (2\rho+1) hc} \left(\frac{2Z}{a_1}\right)^{2\rho-2} Ze^2 r_m^{2\rho-1} \delta r_m$$

For mercury we find  $\rho = 0.81$ ,  $\psi^2(0) \sim 3 \times 10^{26}$  cm<sup>-3</sup>,  
and

$$\delta w \sim 2.5 \times 10^{22} r_m^{0.62} \delta r_m \text{ cm}^{-1}$$

Assuming, as Bartlett,  $r_m = 10^{-12}$  cm,  $\delta r_m = 10^{-13}$  cm,  
we get

$$\delta w \sim 100 \text{ cm}^{-1},$$

which is several hundred times larger than the experi-  
mental value.

It appears now unlikely that  $r_m$  should be con-  
siderably smaller than  $10^{-12}$  cm in order to get the  
experimental values of the displacement, we would  
therefore have to assume  $\delta r_m$  to be of the order of  
 $10^{-16}$  cm, that is,  $\frac{\delta r_m}{r_m} = \frac{1}{10,000}$ . This seems scarcely  
compatible with the fact that the difference in mass  
of successive isotopes is about one hundredth of their  
total mass.

One could question the validity of Schrodinger's  
method of perturbations, as in our case the perturba-  
tion, though extending only over a very limited area,  
is very large. But we may satisfy ourselves with  
respect to this objection in the following way. For  
the type of potential curve near the nucleus assumed

here and a Coulomb field farther outside, the solutions of the Dirac equations can be found accurately, without using approximations, in this case we found good agreement with the approximative method.

My thanks are due to Prof. Pauli and Dr. Delbruck for helpful discussion.

### Electric Arc between Carbon and Substances which are Insulators at Ordinary Temperatures

It is well known that glass, chalk, porcelain, etc., become conductors if they are brought to high temperatures. Using this fact, an electric arc can be started between a carbon electrode and a second electrode of these materials.

With a glass electrode the arc is particularly noiseless, even with alternating current (4-5 amperes, 100 volts). The emitted light is a whitish-golden light of warm tonality. Observation with the spectroscope showed a continuous spectrum, which is originated by the pure arc (without the electrodes), and some bright lines. Some dark lines were also observed, and, among them, the *D* lines, which are remarkably strong. If the arc is projected longitudinally on the slit, some of the dark lines (particularly the *D* lines) show a beaded ('venternodalis') feature. This peculiar feature was also observed by me some years ago under different conditions,<sup>1</sup> but in the glass arc is much more marked.

With a chalk electrode the starting of the arc is more difficult.

In order to start the arc with a porcelain electrode, this must be previously brought to a very high temperature. The arc with a porcelain electrode is very white and bright, it has sometimes explosive properties.

### Vanishing Life of Australia

My attention has been directed to an article in *NATURE* of Sept. 12 last, entitled "Vanishing Life of Australia." As the officer in charge of the Department the function of which it is to protect the native game of this State, a few lines on the subject may not be out of place.

With much of what is said in the article I agree, but some of the statements made are, I fear, rather misleading to the general public. For example, within one hour's motor run of the City of Melbourne—a city of more than one million inhabitants—can be seen kangaroos, lyre birds, and koalas or native bears in their native state, thriving and unmolested by the public. As a matter of fact, there are more kangaroos and wallabies now in this State of Victoria than there were twenty years ago, this being due to adequate protection and the abolition of the market shooter. A similar condition of affairs can be truthfully said to apply to the platypus, that unique paradox which is now common in most of our waters. I have no reason to fear the wiping out of our unique fauna in the immediate future.

The two principal factors in these days accounting for the reduction in numbers of the Australian fauna

are the spread of settlement resulting in the opening up of the country and the difficulty of securing adequate suitable areas for sanctuaries and national parks. However, some of the more beautiful of our cockatoos and parrots, which were nearing extinction a few years ago, have been brought back in greatly increased numbers in recent years, due to strict protection and the proclamation as sanctuaries of their breeding places.

The adequate protection of our rare birds and animals has been made possible by a gradual tightening up of the law. It is now illegal to have in possession, no matter when or where obtained, any of the following birds or animals, or their skins or feathers: Platypus, Koala, Lyre Bird, Rock Pebbler Parrot, Major Mitchell Cockatoo.

This law, which is easy of administration, together with the force of public opinion, has meant not only the preservation of these species, which were tending to become rare, but also their gradual increase, so that they are now more abundant than they were years ago. Furthermore, as an aid in their protection, no permits whatsoever are given to take any of these particular species. Any other native bird or animal may be given the benefit of this special protection at any time, should it be thought there is any need for it, simply by an Order in Council.

These remarks will indicate to your readers that this State of Victoria realises its responsibilities by conserving for future generations the unique birds and animals committed to its care by giving them adequate protection under the law.

F. LEWIS,

Chief Inspector of Fisheries and Game  
143 King Street,  
Melbourne, C.I., Australia,  
Feb. 24

The efforts made, officially and unofficially, to protect the rare creatures of Australia, deserve commendation, but their effectiveness as regards certain species is in some doubt, if we may judge from the opinion of the Council of the Royal Zoological Society of New South Wales (see *NATURE*, Dec. 5, 1931, p. 935). Moreover, Mr. Lewis should have reminded us that the *Melbourne Argus* of Sept. 18, 1931, published six days after our leading article appeared, announced that an individual had been fined £955 5s. for unlawfully consigning 3821 skins of 'opossums', a fact which suggests that the protection afforded by the law is yet far from perfect (see *NATURE*, Jan. 23, 1932, p. 126).

### Electrical Potential Differences across Onion Epidermis

R. J. PUMPHREY, in a careful investigation,<sup>1</sup> has found constant electrical potential differences across epidermis stripped from the bulb scales of onions when this membrane separated unlike solutions of electrolytes. We, on the other hand, had previously observed under similar conditions potential differences which changed with time.<sup>2</sup> Pumphrey offers the suggestion that the fall in potential difference in our experiments was due to diffusion of salt from the KCl bridges used to connect the calomel half-cells with the solutions bathing the membrane.

This was an entirely plausible explanation, but we do not believe it to be the correct one, for the following reasons. In our experiments the KCl bridges were removed from the experimental set-up immediately after each observation. In preparation for the succeeding observation their tips were rinsed with the

particular solution with which each was to make contact, and they were then placed in position. In practically all cases the observed potential difference increased with some rapidity during an initial period of considerable duration, during which several observations were made. If this were due to salts diffusing from the bridges, it would be necessary to make the exceedingly improbable assumption that more than ten times as much salt diffused into the more concentrated solution (0.1 N) bathing the membrane as into the less concentrated solution (0.01 N). Somewhat similar considerations apply to the succeeding period of constant potential difference.

After a time the potential difference ordinarily fell off. Pumphrey's explanation applies better here. However, we noted that in general the shorter the period between the readings, the closer was the correspondence between successive readings, the potential varied with the time rather than with the number of insertions of the bridges. When the interval between observations was long and, therefore, the KCl bridges were not being inserted, the potential fell, nevertheless. For example, in one experiment, using 0.1 M NaCl on one side of the membrane and 0.01 M NaCl on the other, the potential fell from 28 mv to 3 mv during an interval of twenty hours during which no observations were made.

It must be recognised that an appropriate combination of convective streaming and diffusion might be imagined, such as would account for the inconstancy of the potential difference in our experiments. Certain other differences between our experimental procedure and that of Pumphrey might be used as a basis for speculation, did it seem worth while. We regard it as preferable to seek an opportunity to repeat our experiments in such a way as to shed further light on the probable causes of the differences between Pumphrey's results and our own.

#### Photomicrographic Method for Magnification and Recording in High Speed Pressure Indicators

PRESSURE gauges for recording rapidly changing pressures, such as occur in discharge of firearms or explosions in closed vessels, usually consist of a pressure member which rotates a mirror suitably linked to it. The rotation of the mirror is used to give an optically enlarged indication of the deflexion of the pressure member. These methods have attendant disadvantages. In such gauges we have found it possible to use a photomicrographic method of magnification and recording pressure time curves.

The movement of the pressure member is communicated to an operating rod rigidly connected to the pressure member where the maximum movement takes place. The free end of the operating rod carries a needle at right angles to its longitudinal axis and direction of motion. By means of suitable illumination by light, an enlarged image or shadow picture of the edge of the needle is formed on the film of a drum camera used in photographing the records. The enlarged image is concentrated in a direction normal to the long axis of the needle by means of a cylindrical lens so that a linear image in the form of a black and white line is formed on the film of the camera. The

optical system employed for enlarging and recording the very small motions of the needle attached to the operating rod of the gauge is essentially similar to that used for photographic registration with the Einthoven string galvanometer.<sup>1</sup>

In this manner, by dispensing with mirror systems, we have been able to cut down the mass of the working parts of a rifle pressure time recorder of the piston type to about 10 gm. An example of a pressure time curve

FIG. 1

obtained in discharge of a British service rifle is shown in the accompanying photograph (Fig. 1).

We have also employed the system for closed vessel gauges, and found it useful for recording small motions of various descriptions.

#### Temperatures of the Wolf-Rayet Stars

In a recent paper<sup>1</sup> C. S. Beals has published the contour of the emission line of ionised helium 4686 in the spectrum of the Wolf-Rayet star H D. 192163. We may suppose that the mechanism of excitation of emission lines in the spectrum of Wolf-Rayet stars is identical with that of planetary nebulae. According to Zanstra's theory, we can obtain the temperature of star from the ratio

$$\frac{\text{whole intensity of line}}{\text{intensity of } I A \text{ of continuous spectrum}}$$

According to the contour of line 4686, this ratio for the star under consideration is nearly equal to 200. Neglecting the presence of other lines of ionised helium, we find from Zanstra's Table 7<sup>2</sup> the temperature  $T = 65,000^\circ$  as a lower limit. For many Wolf-Rayet stars the intensity of line 4686 is much greater, and therefore we may expect even higher values of surface temperature.

#### Planetary Positions on Medieval Maps

A RECENT issue (Feb. 27) of the *Illustrated London News* contained a reproduction of an old map believed to have been used, and possibly drawn, by Columbus. At the side of the world map is a map showing the celestial 'spheres' according to the Ptolemaic system. It is of special interest because it shows the positions\* of the heavenly bodies approximately as follows: Sun, Aries 0, Moon, Libra 0, Mercury, Aries 22, Venus, Aquarius 17, Mars, Cancer 2, Jupiter, Virgo 7, Saturn, Scorpio 22.

\* Degrees are not given in the figure. I have merely estimated the degree according to the distance of each planet from the commencement of the sign in which it is placed.

The placing of the planets is not symmetrical, nor are they placed symbolically, for example, in the signs described as the 'exaltations' of the planets by Ptolemy. Probably, therefore, they are either placed in the figure at random or are intended to show the positions of the planets at a specific epoch.

Calculation shows that on no day within the last three thousand years were all the planets in or near the positions stated. But if we suppose that the man who first drew the figure was an observer, not a calculator, that his deductions as to position were made from observations extending over a few weeks, and that he could not see Mercury, but merely guessed its position, the celestial 'theme' may have been originally drawn in March A.D. 131. By the time of full moon on March 31 the positions were approximately Sun, Aries 7, Moon, Libra 7, Mercury, Pisces 10½, Venus, Pisces 9½, Mars, Cancer 2; Jupiter, Virgo 20½, Saturn, Scorpio 21. Venus had been near Aquarius 17 about March 12.

The period of Roman rule in Egypt was a period of astronomical activity. Not only have we the works of the famous astronomer Ptolemy from that period, but quite a number of horoscopes. In these the planetary positions are sometimes given fairly accurately, but in others, for example, the horoscope of Tryphon (A.D. 16), and the horoscope of Anubion (A.D. 137), the position of Mercury is quite wrongly given.

The same period is known also to have been a period when there was an interest in map-making, and it is quite conceivable that the map-maker of the fifteenth century copied the figure of the heavens from some older map without knowing what it represented.

I should be glad if anyone who knows about any maps of the Middle Ages, with planetary positions marked on them, would give me information in regard to them.

#### Halibut Liver Oil as a Source of Vitamin A

REFERENCES in the literature that the liver oil of the halibut (*Hippoglossus vulgaris*) is a very rich source of vitamin A (of the order of 50-100 times as rich as cod-liver oil) have been confirmed by me. However, it was soon found that not all samples of halibut liver oil gave such high values, and all potencies from 30 blue units (0.2 c.c. of 20 per cent solution) up to 1600 blue units have been observed. It is to be noted that this irregularity is the rule, and not the exception, in my experience. If halibut liver oil is to become of commercial value as a ready-made vitamin A concentrate (and this possibility is at present being investigated by several manufacturing firms), it is clearly necessary to know something of these fluctuations, whether they are seasonal, etc. This is all the more necessary as, for some reason at present unknown, halibut liver oil cannot be obtained by steaming the livers (as with cod liver oil, for example), and the more expensive process of solvent extraction must be resorted to.

A prolonged series of experiments on this problem of the excessive fluctuations in vitamin A potency of halibut liver oil is being carried out, and attempts will be made to find not only the seasonal effects (if any), but also the influence of the diet of the fish concerned. The work is not sufficiently advanced as yet to draw any definite conclusions.

#### Implements of Late Magdalenian Age underlying the Raised-Beach at Larne, Co. Antrim

IN July 1930 I made the discovery that the Lower Estuarine Clay of north-east Ireland contains a pencontemporaneous and well-developed flint industry of Late Magdalenian age. Subsequent investigations in the company of my friend Mr. C. Blake Whelan resulted in the recovery of several hundreds of these artefacts from the two small exposures of Lower Estuarine Clay on the western shore of Island Magee.<sup>1</sup> The type specimens, exhibiting a distinctive blue patination, have been fully described and illustrated in my last paper.<sup>2</sup>

Lately I have established the fact that the Lower Estuarine Clay which underlies the gravels of the 25-foot raised-beach on the Curran at Larne contains a similar industry to that previously located on Island Magee.

Elsewhere I have, upon archaeological grounds, suggested that a considerable period elapsed between the deposition of the Lower Estuarine Clay and the gravels of the 25-foot raised-beach.<sup>3</sup>

Sections on the Curran appear to offer geological support to the above conclusion. Not only is there evidence that the Lower Estuarine Clay had suffered substantial surface erosion prior to the deposition of the gravels of the 25-foot raised-beach of Early Neolithic times,<sup>4</sup> but also that the period of erosion was followed by the formation of marine sands characterised by a molluscan fauna of wider range in types than that of the overlying raised-beach gravels.<sup>5</sup>

#### Proper Name of the Amœba

THE common little amœba of stagnant waters appears to have no well-established scientific name. I have, to-day, received an elaborate paper, by S. O. Mast and P. L. Johnson, published in *Archiv für Protistenkunde*, 1931, intended to settle the matter. These authors give many apparently good reasons for thinking that the "Kleine Proteus" of Rosel (1755) was in fact a myxomycete. Hence the names applied by Linnæus and Pallas to this organism are not applicable to the amœba.

The final conclusion reached is that the valid name must be *Amœba proteus* Leidy, 1878. But Leidy expressly states that he is using the specific name coined by Pallas, 1766 (*Volvox proteus*). There are no grounds whatever for attributing the specific name to him, and no matter what he described, the type of *A. proteus* is the organism referred to by Pallas.

The generic name *Amœba* is an emendation from *Amiba*, as Leidy states. The earliest specific name under *Amiba*, and the type of the genus, is *A. divergens* Bory, 1822. With this stands or falls the generic name. Apparently the oldest specific name for an amœba in the modern sense is *Proteus diffuens*, which Sherborn ascribes to G. Adams, 1787 (not Muller, 1786, as commonly cited). Mast and Johnson do not think this is identical with the *Amœba proteus* of modern authors, but Schaeffer, who paid much attention to the subject, so considered it. What, then, is the proper name of the common amœba?

## Research Items

**Marriage in Africa**—In *Man* for April, Mr J H Driberg discusses the character of State marriages—the marriages of chiefs and rainmakers—in Africa, and argues that they are not, as is usually held, outside the ordinary rules of African marriage. The ruler's official wife is not his first wife, but the wife he marries after his accession to office. The marriage wealth is not paid by the husband, but is contributed by the whole tribe, and however many marriages the chief may have contracted before, and however many children he may have had, it is the State wife, the cattle for whose marriage has been publicly subscribed, who provides the heir. But if the tribe is the logical and organic development of the family through the clan, this marriage also would have had the clan recognition. Every eldest son of an eldest son, as the representative of his local community, has a State wife, provision for whose marriage has been made by the community at large. This is his first wife. The purpose of the marriage is to ensure continuity and to make possible the reincarnation of an ancestor. The clan is intimately concerned in the provision of a first wife of a member whose status will involve certain religious and economic duties. Therefore, the clan must contribute at least a proportion of the marriage wealth. Occasionally a young man may acquire sufficient wealth to make him economically independent. Even when this happens, the clan will insist on providing a portion of the marriage wealth in order to assert its rights. If, however, the first marriage is contracted without the assistance of the clan, it is not recognised as a clan transaction. The children have no clan affiliation, but form a new clan, of which the husband is the eponymous founder.

**Yurok-Karok Basket Weavers**—A study of the basketry craft of the Indians of the Klamath and Trinity Rivers, California, by Miss Lila M O'Neale (*University of California Publications in American Archaeology and Ethnology*, vol 32, No 1), may be noted as dealing more specifically with the relation of the women to their work than with the technological side of the subject. The basket-work of these Indians has long been marked for its attainment of a high degree of excellence. It is limited, with the exception of minor matters of finish, to the twining technique. In material, form, proportions, and stylised design motives it is moulded by a set of traditions which have been transmitted from generation to generation. As a woman's baskets are destroyed at her death, no baskets of great age are in existence among the Indians themselves. Although the Indians have been in contact with the whites since 1850 and modern ideas have not entirely failed to penetrate, the women who at present make baskets are conscious of the deviations and judge to-day's products by yesterday's criteria. The teacher of the basket maker is generally the mother, if she is living, otherwise the grandmother or an aunt. The child is generally five or six years of age when her first basket is started for her, but it may be another five years before she is able to start a basket for herself. Grown women refer to their training with pride. The actual weaving of a basket presupposes days of preparation in gathering, preparing, sorting, and storing of materials. Small children, extreme old age, or physical disability are the only excuses for not engaging in this preparatory work, and such failure is regretted, as each woman knows that her choice of material for her own work is superior to that of anyone who may do it for her.

**Zebu-Yak Hybrids**—For several years, crosses have been made between zebu Indian cattle and yaks in the Zoological Park at Moscow. Mr M M Zavadovsky has published an account of the results (*J. Heredity*, vol 22, No 10). A zebu bull was originally crossed with a yak cow, producing a female, which was repeatedly crossed with its father. Crosses of the offspring were also made with a hornless yak bull, a total of 14 hybrid animals being produced from this bigeneric cross. The  $F_1$  and  $F_2$  females are fully fertile with both parent species, while the male hybrids are sterile and are shown histologically to produce no sperms. A study of the chromosomes might throw further light on this male hybrid sterility. Heterosis or hybrid vigour occurs in this, as in certain other crosses among the Bovidae. The characters the inheritance of which was studied included coat colour, length of hair, the 'fringe' of the yak, length of tail hair, and shape of hump, horns, and muzzle. The dominance is frequently incomplete, but there is clear evidence of Mendelian segregation when the  $F_1$  is crossed back to either parent. The zebu is grey with short hair, the yak black-brown with long hair and a fringe. The  $F_1$  animals have the yak colour but with hair scarcely longer than the zebu. In back-crosses the black-brown animals were grey-brown until the first coat was shed. The fringe of the yak is almost completely recessive, while the yak type of tail is incompletely dominant, giving intermediate lengths of hair in back-crosses. The yak shape of hump is partially dominant to that of the zebu, the hybrids having no hump at first but developing one in after years. The horns of the  $F_1$  generation are different from either parent, and probably at least two pairs of genes are concerned. The muzzle of the hybrid is intermediate but nearer the zebu, and there is evident segregation in the next generation. Absence of horns is dominant in yak hybrids, as in cattle.

**Origin of the American Fauna**—The discovery of a wide range of mammalian fossils in America has made possible a well-documented history of this group. Briefly, three main elements are concerned: a northern, circumpolar, modern element; a more southerly, older element, and a still more southerly, still older element, the original fauna of South America. It can scarcely be expected, as Emmett Reid Dunn has pointed out (*Copeia*, Oct 1930, p 106), that reptiles and amphibians should show elements so clear-cut as to origin, for they make poor fossils, they cannot stand cold climates and therefore the northern element will be weak, and they are more subject to accidents of environment. Notwithstanding these difficulties, the author's analysis of the distribution of American turtles and other groups of reptiles and amphibians shows that in the basal elements of the herpetological fauna there is surprising agreement with the scheme formulated for the mammals.

**Nematode Disease of Potatoes**—Extensive work on the nematode disease of potatoes has been carried out by Dr D G O'Brien and Mr E G Prentice (*West of Scotland Agric Coll Res Bull* No 2, 63 pp). The history of the study of the parasite is reviewed, and detailed descriptions of the symptoms which it causes on potatoes are given. Variations in morphology, due to adaptation, occur and are described minutely. The relation of the organism to soil environment and its distribution have also received attention. One important fact is that the nematode disease is often

followed by secondary parasites, the chief of which is *Rhizoctonia solani*. The presence of the fungus appears to aggravate the disease, causing 'nematode nests', that is, areas in the potato crop where the plants are unhealthy and rot prematurely. It is interesting to recall, in this connexion, the results of other work (see NATURE, March 5, 1932, p. 367) showing that *Heterodera Schachtli* is mainly responsible for the disease of potatoes known as 'sickness', with which *R. solani* may also be associated as a secondary parasite. Potato sickness and nematode disease are, presumably, but two names for the same malady.

**Climatic Synopsis of Manila**—The annual summary of monthly meteorological data for Manila for each year is in the form of a single sheet two feet wide and more than a foot from top to bottom—a rather awkward-sized document to study. The sheet for 1931 was available in London early in March, a notable feat of the Manila Central Observatory. This Observatory is probably best known to meteorologists as contributing so much to our knowledge of the structure of the typhoons of the Philippines. Manila lies approximately in lat. 15° N and is near the western extremity of the world's largest stretch of tropical ocean, it fails to be ideally placed for providing information about cyclones only in so far as land influences are present owing to the large size of the island of Luzon. The irregular visits of these violent disturbances are to a region which is normally one of extraordinary tranquillity, where barometric pressure may show only the same systematic slight changes according to the time of day for weeks in succession. At Manila, moreover, temperature has varied over a total range of only 43° F since the beginning of 1885—a range occasionally surpassed in less than twelve hours even in the temperate climate of England. Alongside the figures for the different climatic elements for 1931 long period averages are given. These will enable anyone interested in the weather of this part of the Far East to find points of interest in what appears at first sight to be only a dreary collection of statistics, it is a pity, nevertheless, that some short note on outstanding peculiarities of each year cannot be added to supplement the tables.

**Penetrating Radiation from Beryllium**—Dr J. Chadwick's suggestion (NATURE, 129, 312, 1932) that the penetrating radiation produced when beryllium is bombarded with  $\alpha$ -particles consists of neutrons has been discussed by F. Rasetti in *Die Naturwissenschaften* (April 1, p. 252). Rasetti has obtained results in agreement with the neutron hypothesis, in that he has been able to repeat the earlier work with the Wilson expansion chamber, and to photograph trails attributed to hydrogen, helium, and carbon nuclei which have received energy from the neutrons. His work is not obviously in accord with this, in that it appears quite easy to prevent individual units of the beryllium radiation from passing consecutively through both of two Geiger-Müller counters, coincident discharges of the two can be completely stopped by the interposition of 5 mm of aluminium between them, which should not affect neutrons appreciably. This corresponds, however, to the absorption of electrons set free by the recoil from a 10 million volt  $\gamma$ -ray quantum, and to overcome this difficulty it is suggested that the beryllium radiation is a mixture of both neutrons and  $\gamma$ -rays.

**Examination of Turbulent Flow with an Ultramicroscope**—A. Fage and H. C. H. Townend have described an ultramicroscope method for studying turbulent flow which has been developed at the National Physical Laboratory (*Proc. Roy. Soc.*, April). Ordinary tap water contains many particles which can be used

for this purpose, being small enough to show Brownian movement when the water is at rest, and appearing in the objective as bright streaks when strongly illuminated with the fluid moving. The local movement of the fluid can be found from the appearance of the streaks. Although it was found that only ocular observations could be made, photographic recording proving impracticable, the method is specially valuable, both because no instruments have to be put in the fluid and because the use of a microscope restricts the volume under observation at any instant. The results are not readily compared with von Kármán's theory of turbulence, but the prediction that the velocity fluctuations on the axis of the pipe are zero is wrong, fluctuations amounting to 20 per cent of the mean rate of flow being observed. At the wall, the flow tended to a laminar type, but the motion of the particles in the laminae remained sinuous even to within 1/40,000 in. of the boundary, no particle being seen to move in a rectilinear path. A further observation made was that as the rate of flow was increased through the critical range of the Reynolds's number, the changes of flow occurred with great suddenness, there was no sign of a growth in the degree of turbulence, but only a change in the relative frequency and duration of rectilinear and turbulent flow.

**Magnetostriction in Strong Fields**—In three recent papers (*Roy. Soc. Proc.*, April) Prof. P. Kapitza has extended considerably the theory of the change in dimensions of a body in a magnetic field and the technique for measuring this. The first paper contains an account of the generalised thermodynamics of the effect for crystals, based largely on Voigt's work. The second describes the modifications necessary in the magnetic balance to convert it into an extensometer, the extraordinarily high sensitivity to length changes of  $2 \times 10^{-7}$  cm has been attained. In the third, the new methods are applied to a detailed study of bismuth and a less complete study of antimony and some other feebly magnetic bodies (graphite, gallium, tungsten, tin, beryllium, magnesium, and rock-salt), not all of which gave a measurable effect. For bismuth, the change in length in weak fields is proportional to the square of the field in all circumstances, but in strong fields at low temperatures there is marked deviation from this law. The sign of the effect is different for the trigonal and perpendicular axes, and the total effect quite small on this account in multicrystalline specimens. For certain axes in bismuth an irreversible change occurs, which has been called 'magneto-slipping'. This is the first occasion on which magnetostriction has been observed for other than ferromagnetic substances, and the experiments are to be extended to transverse and volume effects, whilst the results of some experiments on ferromagnetics in strong fields have still to be published.

**The Quinhydrone Electrode**—Lammert and Morgan (*J. Amer. Chem. Soc.*, March) report further experiments with the quinhydrone electrode which will be of interest to users of this apparatus. They find that, in acetate and phosphate buffer solutions of pH 4.6–5.0 and 6.1–6.5 respectively, it gives results of fair precision, the average potential differences between two like electrodes being about ten times as large as the corresponding averages in 0.1M hydrochloric acid. In unbuffered salt solutions in the neutral range, however, the behaviour may be very erratic, particularly if gold or graphite electrodes are used, and the error, due to lack of reproducibility, may be far greater than any constant error calculated by Sørensen and described as 'salt error'. The rôle of the electrode substance in the quinhydrone half

cell cannot be neglected, and must be tested for each particular system in which the electrode is to be used. The authors conclude that the quinhydrone half-cell, whilst providing an excellent secondary standard, must be used with great discretion as a working electrode, its use being preceded by a study of its reproducibility in the system under investigation.

**Micro-Methods and Enzyme Studies**—Almost the whole of our knowledge of enzyme action is based on the behaviour, *in vitro*, of enzymes isolated from the tissues. While this may give valuable information of the mode of action of enzymes secreted from the tissues, it is clear that for the majority of intracellular enzymes there can be no comparison between the conditions in the reaction medium, *in vitro*, and those which obtain in the cell. Furthermore, the methods of extraction themselves are in many, if not most, cases such as to leave it certain that radical alterations in the properties of the enzymes will ensue during extraction. The recognition of problems such as these has led K. Linderström-Lang and H. Holter (*C R Lab Carlsberg*, 19, No 4, 1931) to consider what degree of refinement in existing methods is required. In their judgment, an increase of delicacy of about one hundred thousand times would suffice to study the enzymatic activity of a single cell, but methods capable of measuring changes one thousand times as small as those detected by current macro-methods would remove most of the difficulties experienced. They have therefore devised a method of this degree of refinement for following the hydrolysis of a peptide by malt peptidase. The amino nitrogen is estimated in acetone by titration with *N*/20 alcoholic hydrochloric acid and naphthyl red, thus eliminating the effects of carbon dioxide on the end point. The apparatus is simple, and the mean error on a titration

of 20 c mm is of the order of 0.03 c mm. Now a section of a root  $40\mu$  thick weighs approximately 0.003 mgm and it contains only about 300 cells. This, in suitable circumstances, will break down sufficient peptide to give a result thirty times greater than the probably experimental error. Evidently, on this basis, the presence or absence of activity in 10-20 cells could be demonstrated.

**Creep Tests on Steel for Steam Plant**—In a paper entitled "Testing of Materials for Service in High-Temperature Steam-Plant", by R. W. Bailey and A. M. Roberts, read to the Institution of Mechanical Engineers on Feb 19, particular reference was made to the creep tests required for steels used for turbine discs and cylinders, steam pipes, boiler tubes, superheater tubes, and bolts for steam joints, which during their working life are subject to stress at high temperatures. The subject of creep, which has become of increasing importance in power station practice, was first brought before the Institution in 1924 by Prof. F. C. Lea, whose experiments were begun in 1915. Since 1924 the subject has been studied by Dickenson, Tapsell, Baumann, Batson, and others, and investigations on creep at high temperatures are being made at the National Physical Laboratory and at the works of the Metropolitan-Vickers Electrical and Manufacturing Co., Ltd. It was with the researches by this company the authors were mainly concerned, and in this paper they gave the results of many tests, some of them lasting over thousands of hours, discussed the various phenomena observed in materials subject to stress at high temperature, described the plant and instruments used, and made suggestions as to the tests which should be required by the manufacturers. The paper is fully illustrated with curves, diagrams, and photographs.

### Astronomical Topics

**The Reinmuth Object**—Drs. Whipple and Cunningham found a parabolic orbit for this object. Dr. Stracke gives the following elliptical orbit from observations on April 24, 27, and May 1 (*Reich Inst Circ* 604):

|          |                       |
|----------|-----------------------|
| $T$      | 1932 July 8 9999 U T  |
| $\omega$ | $284^\circ 36' 05''$  |
| $\Omega$ | $35^\circ 54' 38.5''$ |
| $i$      | $5^\circ 53' 35.4''$  |
| $\phi$   | $31^\circ 52' 33.2''$ |
| $\log q$ | 9.8216414             |
| Period   | 1.6659463 years       |

This orbit satisfies the following observation by Dr. W. H. Steavenson within about  $3''$ , the discordance of the parabolic orbit is considerably greater.

May 6<sup>d</sup> 0<sup>h</sup> 27<sup>m</sup> 3<sup>s</sup> U T, R. A. (1932.0) 12<sup>h</sup> 31<sup>m</sup> 29<sup>s</sup>,  
S. Decl.  $11^\circ 2' 68''$

There is also the fact that the parallactic shift in R. A. between two Heidelberg positions on April 24 is  $23''$  by observation,  $20''$  as calculated from the ellipse, and  $10''$  from the parabola. There are therefore good grounds for supposing that the ellipse is nearer to the truth. If so, the object is still more remarkable than the Delporte planet. Its perihelion point is inside the orbit of Venus, and it passes within about 3 million miles of the earth's orbit at two different points. Its period is only half that of Encke's comet, so that even as a comet it would be remarkable, but its aspect appears to be quite stellar. Observations are urgently needed, as the object will be lost in the twilight before long. Dr. Stracke gives the following ephemeris for 0<sup>h</sup>

|        | R. A.                                         | S. Dec.           | $r$   | $\Delta$ |
|--------|-----------------------------------------------|-------------------|-------|----------|
| May 14 | 9 <sup>h</sup> 48 <sup>m</sup> 1 <sup>s</sup> | 9 <sup>°</sup> 2' |       |          |
| 15     | 9 21 1                                        | 7 25              | 1.015 | 0.070    |
| 16     | 8 54 0                                        | 6 26              |       |          |
| 17     | 8 27 7                                        | 5 22              | 0.997 | 0.072    |
| 18     | 8 2 8                                         | 4 18              |       |          |
| 19     | 7 39 7                                        | 3 15              | 0.978 | 0.077    |

The nearest approach to the earth,  $6\frac{1}{2}$  million miles, is on May 15.

**A New Kind of Eclipse Map**—*Monthly Notices* of the Royal Astronomical Society for March has a map of a novel kind to illustrate the eclipse of Aug. 31 next. Prof. S. Chapman contributes a paper on the influence of a solar eclipse on the ionisation of the upper atmosphere. It is important to use the coming eclipse to test the theory that the lower ionised layer in the atmosphere, the height of which is stated to be about 100 km, is ionised by neutral corpuscles emitted by the sun. Since these corpuscles travel much more slowly than light, the region of the earth that is affected by them differs considerably from the region of optical eclipse. Also, the screening is shown to be efficient over a region of the earth much larger than the zone of totality, in fact, it is nearly as large as the region of partial eclipse. It is shown that the axis of the shadow cylinder of the corpuscles will strike the earth two hours earlier than the optical shadow-cone, and that the British Isles and western Europe enjoy corpuscular eclipse, though they are outside the optical shadow. The map was drawn by Mr. J. C. P. Miller, at Prof. Chapman's request. It brings out the curious fact that a small portion of the track of optical totality is outside the region of corpuscular eclipse.

### Conditions of Air in Tunnels\*

ADEQUATE ventilation of tunnels assumes a fresh importance when a continuous stream of vehicles driven by internal combustion engines and coal-fired steam waggons is passing through them. From the progress of such vehicles in the tunnel products objectionable to health may arise, such as carbon monoxide and suspended sooty matter from incomplete combustion, moisture from the combustion of hydrocarbons, sulphur, for the most part, from coal, and lead from petrol treated with lead ethyl. A report on the actual condition of the air in two of London's tunnels is consequently of interest.

The condition of the air in the tunnels at Blackwall and Rotherhithe has been the subject of study by the chemical staff of the London County Council, determinations of carbon monoxide, suspended matter, and the relative humidity having been made during a period of nearly two years. In addition, determinations of the sulphur impurities were made from time to time by members of the staff of the Government Chemist, using the methods recently devised for the Committee on Atmospheric Pollution.

Under normal conditions of traffic, the highest concentration of carbon monoxide found in these tunnels was 3.1 parts in 10,000 of air, but on the occasion of a severe traffic block caused by an accident at Blackwall a value as high as 11.5 parts in 10,000 was obtained. It is noteworthy that the highest concentration of carbon monoxide found by workers in the United States in the New Jersey tunnel was 8 parts in 10,000, and that the average values were between 3 and 4 parts in 10,000. Further, the maximum concentration of carbon monoxide found by the Ethyl Petrol Committee in traffic blocks in the streets of London was 1.7 part in 10,000.

During the period covered by the tests, extraction fans were installed at one position at Blackwall, whereupon an improvement in the condition of the air at that place was observed. From the work of Haldane, Douglas, and Hartridge in Great Britain and of Henderson and his co-workers in the United States, it may be concluded that no appreciable physiological effect is produced by carbon monoxide in concentrations not exceeding 3 parts in 10,000 of air when breathed for 1 hour. Mr. Regan recommends, there-

\* London County Council. Annual Report of the Council, 1930 Vol. 4 (Part 3). Public Health. Medical Supplement to the Report on the Hospital Services. Page 271. The Ventilation of Vehicular Tunnels with Particular Reference to those at Blackwall and Rotherhithe. By C. J. Regan.

fore, that the proportion of carbon monoxide in the air of the tunnels should not be allowed to exceed 2 parts in 10,000.

Suspended matter determined by the Owens portable air filter was indicated by 12 fog-shade units as a highest value under normal conditions of traffic at both Blackwall and Rotherhithe, each fog-shade unit representing 0.32 milligrams of black suspended matter in a cubic metre of air, while a reading above 10 indicates a dense fog. It is recommended that the maximum permissible reading for black suspended matter should be 6 fog-shade units.

Since at no time did the relative humidity of the air in the tunnels approach 100 per cent, the fogs observed from time to time were smoke fogs, not water-vapour fogs. It was found, too, that when the average daily temperature outside the tunnels was above 58° F. the average humidity in the tunnels was above that of the outside air. Usually, however, the reverse was the case.

The average quantities of sulphur dioxide found at Blackwall and Rotherhithe were 0.26 and 0.51 parts per million, respectively. These values, while not being excessive, are somewhat higher than the average figures, namely, about 0.13 parts per million, for the air of London given on page 48 of the seventeenth report (for the year ended March 31, 1931) of the Committee on Atmospheric Pollution.

The possibility that the air in the tunnels might contain lead was not overlooked, but no experimental work has been carried out up to the present time. It is fortunate that there is available in the results obtained by the Ethyl Petrol Committee a datum line for the quantity of lead occurring in the dust of the streets of London. On the average the settled dust of the streets contains 0.35 per cent of lead. If, therefore, the air of the tunnels were to become polluted with lead owing to an increase in the use by motor vehicles of leaded petrol, it is to be expected that the proportion of lead then found in the air would be greatly in excess of this value.

As a result of the investigation it is concluded that the atmospheric conditions in the tunnels are worst about 10 A.M., that they are worse in summer than in winter, and particularly when the temperature of the outside air rises above that of the tunnels. Additions to the ventilating plant at both tunnels are being made, and those at Blackwall are well advanced towards completion. A. G. F.

### Nutrient Salts in the Mediterranean

THE well-known sterility of the Mediterranean Sea compared with the neighbouring waters of the Atlantic Ocean finds a ready explanation in the chemical investigations carried out on board the Danish research vessel *Dana* by Helge Thomsen in the summer of 1930\*. Determinations were made at all depths at stations in the southern Mediterranean of the nutrient salts, phosphate and nitrate, known to be essential for the growth and reproduction of the phytoplankton, which in turn form the foodstuff, directly or indirectly, of almost all other life in the sea. The results are striking.

In the Mediterranean the concentrations of both salts are much less than in the great oceans of the

world at similar depths. In depths greater than 200 metres the maximum nitrate content is everywhere 3-4 times greater in the Indian and Pacific Oceans and 2-4 times greater in the Atlantic than in the Mediterranean. For the minimum values the corresponding ratios are very high (of the order 8-23) in depths between 200 metres and 600 metres in accordance with the very low minimum values in the Mediterranean. Further, below 400 metres depth the maximum values for both phosphate and nitrate in the Mediterranean are less than the minimum values in the oceans.

In the surface waters, interpretation of the very low results found is more difficult, since so much of the work both in the Mediterranean and in the oceans in higher latitudes has had to be done in summer, when the salts could conceivably have been depleted by a preceding spring outburst of diatom growth. The region of complete depletion (less than 5 mgm. phos-

\* "Nitrate and Phosphate Contents of Mediterranean Water." Report on the Danish Oceanographical Expeditions, 1908-10, to the Mediterranean and Adjacent Seas vol. 3, *Miscellaneous Papers*, No. 6, pp. 14. Copenhagen, 1931.

phate ( $P_2O_5$ ) or 10 mgm nitrate nitrogen per cubic metre) usually extended down to 150-200 metres, and in this connexion red algæ have been found growing in this sea down to 130 metres, far below the limit to which sufficient light could penetrate in the more turbid northern waters † Thus it would seem that the very scarcity of nourishment and resulting sparseness of sub-surface life enables light to penetrate far into the water for plants there to utilise the minute quantities of phosphate and nitrate which diffuse up from the meagre bottom store. Perhaps indeed, in the Mediterranean the region most favourable for planktonic organisms may be far removed from the surface, at, say, 100 metres, where a sufficiency both of light and of nutrient salts are found together. This is far lower than is found anywhere in waters around Great Britain. Experimental data on the amount and quality of the light penetrating to such depths and of its suitability for photosynthesis should prove illuminating.

† Harvey, H. W., "Biological Chemistry and Physics of Sea Water" Cambridge, 1928.

The concentrations of both phosphate and nitrate decrease going eastward from the Straits of Gibraltar. In the Aegean Sea phosphates were not detected at any depth, and nitrates were very poor. It is manifest that life cannot flourish on any considerable scale in such impoverished waters. In the Straits of Messina nitrate appeared to be comparatively high, apparently due to vertical mixing, but it was unaccompanied by phosphate and was presumably therefore of little value.

The scarcity of nutrient salts in the Mediterranean is attributed by Thomsen to the exchange of water through the Straits of Gibraltar, since Atlantic surface water, already poor in nitrate and phosphate, runs in over the outgoing bottom current of Mediterranean water. This exchange of water has been well established by several vessels, including the *Dana*, and Thomsen's own analyses in the Straits and the Alboran Sea testify to the impoverishment of the inflowing Atlantic surface water, at any rate in April and June.

### Acoustic and Telephone Measurements

IN a paper read by H. R. Harbottle to the Institution of Electrical Engineers on April 8, a brief description is given of some of the work carried out in the research section of the British Post Office. He begins by discussing electro-acoustic and acousto-electric measurements of instruments. He next describes voice-ear measurements on microphones and receivers, and finally deals with mechanical tests by means of which rapid acceptance tests can be made and estimates given of the commercial life of instruments.

Mr Harbottle attributes the progress made during recent years to the methods invented of expressing the results of measurements in telephony by reference to absolute units. These methods followed on the invention and development of the thermionic valve. This has enabled acoustic pressures and velocities to be measured accurately, and has led to the rapid advances made in radio-telephony. This in turn has promoted world-wide telephonic communication.

To enable this to be done, an international committee had to be formed, called the C. C. I.—Comité Consultatif International des Communications Téléphoniques à grande distance—the objects of which were the formulation of correct methods of measurement. Standard instruments were required which had to give a constant response over the range at which they were used. At the present time this can only be achieved by the use of insensitive instruments in which the mechanical resonances have been removed outside the working range by increasing or diminishing the stiffness. The output is then raised by a thermionic valve amplifier suitably applied. A wide field has been found for these instruments in broadcasting, sound pictures, and gramophone reproduction.

The instrument used at the present time as a work-

ing standard in most acousto-electric and electro-acoustic measurements is a condenser microphone. It consists of a thin aluminium diaphragm, gold-plated to prevent oxidation, forming one plate of the condenser, the other being a circular insulated brass electrode. This is grooved, and is fixed at a small distance away from the other plate. The space between them is practically sealed, and so adds 'stiffness' to the diaphragm. Due to this, the frequency of natural resonance is effectively suppressed.

The microphone is polarised by applying 200 volts across it. Its vibrations cause variations in the capacitance, and consequently it acts like a generator producing electric currents. It is calibrated by one of three methods—the thermophone method, recommended by the C. C. I., the Rayleigh disc method, or the compensator method. The results obtained by these methods have been found by the Post Office to agree satisfactorily.

By means of an automatic device the life test of a carbon microphone can be reduced to about one-fiftieth of the normal time taken. A current is first switched on—this represents the lifting of the receiver from the switch hook. A klaxon is next operated momentarily—this simulates the removal of the receiver by the subscriber. 7.5 seconds later the microphone is subjected to a rhythmic 'howl-warble' tone for 7.5 seconds, and this tone is repeated seven times at intervals of 7.5 seconds. At the end of 1½ minutes the klaxon is momentarily operated and the current switched off. There is then an interval of 1.5 minutes and the cycle begins again. In a week's time the wear on the telephone is the same as that made by a subscriber who in a year makes a thousand calls.

### South Sandwich Islands\*

THE first of the two *Discovery* Reports before us is the list of stations 137 to 433 made by R. R. S. William Scoresby in the seas between South Georgia, the Falkland Islands, and the South Shetlands from January 1928 to May 1929, and other stations made

by members of the *Discovery* investigations staff from whale factory ships about the South Sandwich Islands and in the Ross Sea. This follows the first station list published in an earlier volume of the *Discovery* Reports.

The second report under notice deals with the South Sandwich Islands. These islands were discovered by Cook in 1775 and Bellingshausen in 1819, but they lie in stormy and frequently ice-invested seas off the track of most antarctic expeditions, and have been rarely visited except by sealers and whalers until the *Discovery* spent twenty days among the group in

\* *Discovery* Reports. Issued by the *Discovery* Committee, Colonial Office, London, on behalf of the Government of the Dependencies of the Falkland Islands. Vol. 3. Station List, 1927-1929. Pp. 132+10 plates 14s 6d net. The South Sandwich Islands. By Dr Stanley Kemp and A. L. Nelson, with a Report on Rock Specimens, by Dr G. W. Tyrrell. Pp. 133-198+plates 11-31. 18s net. (Cambridge At the University Press, 1931.)

February and March 1930 The eleven islands, extending in a chain of 193 miles, are all small and volcanic The largest has a circumference of only twenty-four miles Landing is always difficult and on some islands perhaps impossible Sulphurous fumes in places are a menace The *Discovery* found no active volcanic eruptions, though five islands were emitting vapours and fumes There were indications that volcanic activity is abating, and three islands show no recent signs of it The rocks collected were all typical Andean lavas, as described by Dr Tyrrell, and confirm Suess's theory of a South Antillean arc The conspicuous 'deep' to the east, sinking to 4421 fathoms, is another noteworthy feature The only possibility of sedimentary rocks in the whole group appears to be in Freezeland Peak on Bristol Island but no landing was achieved there Some of the islands have ice-caps others have foreland glaciers Vegetation seems to be confined to a few lichens and algae No flowering plants were seen Fur seals were not found, though they probably occurred in the past The volume contains maps and photographs of all the islands, and also an Admiralty chart of the group It is a fairly complete monograph on the islands

R N R B.

### University and Educational Intelligence

CAMBRIDGE—An election to an Isaac Newton Studentship will be held early in the Michaelmas Term, 1932 These studentships are for the furtherance of advanced study and research in astronomy and physical optics Members of the University are eligible who have obtained a degree in the University and were under the age of twenty-five years on Jan 1, 1932 failing such a candidate, a research student, subject to the same condition as to age, may be elected The studentship will be of the value of £250 a year, and will be tenable for three years Applications should be sent to the Vice-Chancellor between Oct 7 and 13, 1932

Candidates for the Michael Foster Studentship in physiology are requested to send their applications, with a statement of the course of research they propose to undertake, to Prof J Barcroft, Physiology School, before the end of June The student receives the annual value of the fund (about £100)

At Jesus College, Dr W H Thorpe has been elected a fellow He has been a research fellow of the Rockefeller Foundation at the University of California and a member of the research staff of the Imperial Institute of Entomology At St John's College, Dr L Rosenhead has been elected a fellow He entered the college with an Open Strathcona Research Studentship for mathematics, and in 1930 was elected a Senior Research Student of the Royal Exhibition of 1851

LONDON—Applications are invited for the Laura de Saliceto studentship for the advancement of cancer research, value £150 annually and tenable for not less than two years Applications should reach the Academic Registrar, University of London, South Kensington, S W 7, by July 1 at latest

OXFORD—The proposed regulations for the new Final Honour School of Geography are now published, and will be dealt with by Congregation in due course The stated subjects include physical and regional geography, cartography, the geography of man, and the history of geographical discovery In addition to these, a special subject may be offered The examination will be partly practical, and will include laboratory and field work Candidates will be required to show sufficient knowledge of French or German and of the elements of physics and biology

READING—Dr William B Brierley, since 1918 head of the Department of Mycology in the Institute of Plant Pathology at the Rothamsted Experimental Station, has been appointed professor of agricultural botany in succession to Prof J Percival, who is retiring next September

THE usual summer vacation course for teachers will be held at Bingley Training College, Yorks, on July 27–Aug 10 Among the courses available are one on biology by Prof R Douglas Laurie, professor of zoology, University College, Aberystwyth, and another on the senior school, by Sir Percy Nunn, director of the University of London Institute of Education Application should be submitted not later than June, while grants-in-aid applications must reach the Education Officer, County Hall, Wakefield, not later than May 31

THE University of Cambridge publishes annually abstracts of dissertations approved for its Ph D, M Sc, and M Litt degrees (Cambridge At the University Press, 1932) These summaries, each of which has been approved by the examiners or supervisor of studies, afford a convenient index to the scope of recent advanced study and research in the University The sixty-one dissertations for the year 1930–31 are distributed among the faculties as follows Physics and chemistry 24, biology 11, mathematics 8, agriculture 4, engineering 3, archaeology and anthropology 2, history 2, geography, medicine, music, moral science, economics, English, and classics one each Thirty-eight of the candidates had previously studied in other universities, namely Liverpool 5, Wales 4, Scottish universities 4, other universities in the British Isles 4, universities in Canada, South Africa, Australia, and New Zealand 11, in India 7, in the United States of America 2, Switzerland 1

COMMERCIAL education in the United States is reviewed in *Bulletin* No 20, 1931, of the Office of Education, Washington, being advance pages of the official Biennial Survey (1928–30) of Education in the United States Few people have any idea of the enormous amount of time and energy devoted in the United States to commercial education and to the investigation and discussion of the principles and methods employed in this field in secondary schools and universities More than a million young men and women are enrolled in business courses, exceeding the number in any field of vocational training, and during the past ten years there was an increase of more than three hundred per cent in such enrolments in colleges and universities At this rate the schools of commerce will soon be throughout the States, as they are already in many institutions, the largest of the professional and vocational university schools At the Congress of Universities of the British Empire, held at Edinburgh last July, the subject of commercial education figured prominently, and reference was made to the resistance of British universities to the dangers of being stampeded into endeavouring to make university education more 'practical', with the deplorable results experienced in American universities This bulletin recounts facts which tend to discount the force of this criticism and show that we have something to learn not only from their mistakes but also from their thoroughgoing investigation of principles and methods The bulletin contains summaries of the results of these and other investigations, and will, doubtless, be in request at the International Conference on Commercial Education to be held in London this year It is obtainable, price 10 cents, from the Superintendent of Documents, Government Printing Office, Washington, D C

## Calendar of Geographical Exploration

May 18 (or 20), 1499 — Amerigo Vespucci

Alonso de Ojeda sailed from Cadiz, with Amerigo Vespucci on board one of his vessels. Vespucci was a contractor for ship's provisions, and did not, apparently, go to sea until he was more than forty years of age. He claimed to have made four voyages to the New World, in 1497, 1499, 1501, and 1503. The first and third voyages are rejected by many, but not all, students. However this may be, there is no doubt that Vespucci went with Ojeda on his voyage, though the two men were not on the same boat, Ojeda reaching the coast of America near Surinam and proceeding to Maracaibo, while Vespucci reached it in 5° S, roughly. In his third voyage, Vespucci claims to have sailed along the east coast of South America from 5° to 50° S, a voyage which, if genuine, gives him a high place in exploration. According to Vespucci's own statement, he had on his first voyage reached the mainland on June 16, 1497, namely, 8 days before John Cabot. The name America appears to have resulted from a copy of Vespucci's letter about this voyage reaching the professor of cosmography at St. Dié University (Lorraine), who suggested in his "Cosmographiæ Introductio" (1507) that the newly discovered land should be called "America, because Americus discovered it."

May 19, 1845 — Sir John Franklin

Sir John Franklin left England for Cape Walker, whence he hoped to reach Bering Strait. He wintered on Beechey Island, and next summer proceeded southward down Peel Sound, spending the second winter in 70° 5' N, 98° 23' W, on the pack ice, where the ships were held fast all through the summer of 1847. Franklin died on June 11, 1847; the party deserted the ships in April 1848, and tried to penetrate south by land, but all perished. The numerous parties organised to try to obtain information about Franklin's fate resulted in great additions to geographical knowledge of the American arctic. News of Franklin's fate was first obtained from Eskimo in 1851, and in 1859, Hobson, a member of McClintock's expedition, found a sheet of paper on King William Island recording briefly what had happened up to the attempt to escape overland. Franklin's first arctic voyage was undertaken in 1818, when he was in charge of one of the vessels in Buchan's expedition. In 1819 he was leader of an expedition which resulted in the charting of much of the unknown coast-line of North America and occupied three years. This and a further journey in 1826 added 1200 miles of coast-line to the map of arctic America. From 1836 until 1843 he was lieutenant-governor of Tasmania (van Diemen's Land). Renewed interest in the polar regions at the time of his return to England led to his last and tragic journey.

## Societies and Academies

## LONDON

Royal Society, May 5 — A. V. Hill. A closer analysis of the heat production of nerve. The heat production of nerve is believed to occur in two phases, 'initial' and 'recovery'; the former is presumably an accompaniment of the physical and chemical changes which take place during the propagation of the impulse, the latter, of the processes by which those changes are reversed and the nerve restored to its initial state. It is not easy to separate the one from the other. The possibility that the initial heat is due to phosphagen

breakdown or lactic acid formation is discussed; the quantities available are sufficient — H. E. Roaf. The influence of coloured surrounds and coloured backgrounds on visual thresholds. Exposure of the retina to light raises the differential threshold. For the fovea, the chief influence in raising the threshold is the simultaneous exposure to light, and for the parts of the retina outside the fovea there is considerable spread of effect from one part of the retina to another. The influence of wave-length on the results is very striking with foveal vision, as 'red' light raises the threshold for all parts of the spectrum, but 'green' and 'blue' lights have a negligible effect on the long wavelength end of the spectrum — N. Gavrilescu, A. P. Meiklejohn, R. Passmore, and R. A. Peters. Carbohydrate metabolism in birds. The site of the biochemical lesion in avian polyneuritis. Oxygen uptakes of normal and avitaminous birds have been measured. The results suggest that vitamin B<sub>1</sub> deficiency is connected essentially with the intermediary metabolism of carbohydrate.

Geological Society, March 23 — William S. Boulton. The rocks between the Carboniferous and Trias in the Birmingham district. The succession at Wyndors Street Gas Works in east Birmingham is continuous to a depth of more than 1000 feet, and includes the Bunter (with a basal breccia), the Nechells breccia, and part of the calcareous conglomerate group. The content of the breccias and conglomerates was described, and a graph was given showing the percentage distribution of rock types at different depths. The heavy mineral residues of the associated sandstones have also been determined. The Barr Beacon beds underlying the Bunter Pebble beds, mapped by the Geological Survey as Hopwas breccia, are of Bunter age, and with them were correlated the breccias at Tower Hill, near Hamstead, and also the more extensive beds of sand-rock at the base of the Bunter of Cannock Chase. The breccias of Hopwas, Sutton Park, Warley, Northfield, and the Lickey, though discontinuous deposits, are of the same general age, and have all been derived from highlands to the immediate east and south, the outcrops of which mainly consisted of Uriconian felsite- and andesite-tuffs and lavas, and basalts. Extensive and prolonged erosion accompanied and followed the Hercynian earth-movements in the area.

## LEEDS

Philosophical and Literary Society, March 1 — E. C. Stoner. The correlation of the gyromagnetic ratio and the magnetic moment of paramagnetic salts. The observed magnetic moments and gyromagnetic ratios are compatible with each other, and may be accounted for by considering the interaction between the spin and orbital moments of one ion and the interaction of the ion with its surroundings — G. W. Brindley. On the refraction of X-rays by perfect crystals. If the *atomformfaktor*  $f$  is incorporated in Ewald's treatment of the reflection of X-rays by perfect crystals in the way suggested by Darwin's earlier treatment of the subject, then the refractive indices of calcite for X-rays calculated from the observed widths of reflections are in good agreement with values obtained in other ways. The agreement is not good if the *atomformfaktor* is omitted — E. C. Pollard. Nature of the potential barrier of the nitrogen nucleus. Experiments have been carried out on the variation of the yield of protons produced by fast  $\alpha$ -particles from nitrogen as the energy of the impinging particle is reduced, the aim being to determine whether the  $\alpha$ -particle enters the nucleus by resonance or by scaling the potential barrier. The results appear to show that resonance does not occur, entry is over the

top, and an approximate estimate of the height of the nuclear barrier is given—H M Dawson and W Lowson. The catalytic effect of acids on the rate of ester hydrolysis in relation to the ester concentration and the nature of the acid. The nature of the process which is involved in the acid catalysed hydrolysis of ethyl acetate is discussed and consideration given to the conditions under which the velocity of the reaction may be used as a measure of hydrogen ion concentration. A comparison of the catalytic effects produced by hydrochloric, chloro-acetic, glycolic, and acetic acids at ester concentrations ranging from 10 cc to 60 cc ester per litre shows that the ionisation constants of the weak acids decrease continuously as the ester concentration increases. Extrapolation to zero ester concentration is necessary if strictly comparable values are to be obtained—C H Douglas Clark. Spectroscopy and valency. (1) The periodic groups of atoms and ions. The classification previously proposed for atoms in ground states has been extended to the rare earth elements, to inert gas-like ions, and to ions of transition elements. The electron groups  $s^2$ ,  $p^2$ ,  $d^{10}$ , and  $f^{14}$  tend to show central symmetry in respect of electron spins in ground states, with maximum valencies and maximum possibility of variable valencies near the centres of the groups, whilst departures from central symmetry are accompanied by the appearance of irregularities in valency. Such departures afford interpretation of the anomalous valencies of transition elements. The evidence of ionisation serves to confirm the views put forward—N. Gill. The phloem of ash, *Fraxinus excelsior* Linn., its differentiation and seasonal variation. Production of large sieve tubes, each usually having a single companion cell in transverse section, begins in spring and continues throughout the summer, being most vigorous when the leaves are fully expanded. Just before leaf fall a modified type of sieve tube is produced, and is characterised by a smaller transverse area and a larger proportion of cambiform companion cells. No further phloem is produced after leaf fall until the following spring.

## PARIS

Academy of Sciences, March 29—A Buhl. New integral invariances connected with differential equations containing several parameters—Émile Sevín. Concerning the energy of matter—Nicolas Kryloff and Nicolas Bogoluboff. The phenomena of demultiplication of frequency in radiotechnics—G Reboul. A particular mode of activation of matter—Rene Audubert and Mlle Cecile Stora. The photovoltaic properties of cadmium sulphide. The sensibility of cadmium sulphide with regard to various radiations of the visible spectrum has been determined, and the results given graphically. If photo-electronic phenomena intervene, they play only a secondary part—Maurice Billy and Mlle Irène San-Galli. A new method of investigation for the study of the hydrated peroxides—C T Popesco. The effects of a new system of grafting in *Lycium vulgare* placed on the tomato—Mlle Odette Tuzet. The centrols of the egg of the sea urchin, *Paracentrotus lividus*—Victor-Pauchet and A Becart. The gastro-photographic method and its automatic means of control.

## GENEVA

Society of Physics and Natural History, Feb 4—Arnold Pictet. Inheritance of polydactyly in the guinea-pig. Polydactyly arises from the union of two parents of a polydactyl strain. One of the parents contributes a factor of intensity, the other a factor of intensity in the heterozygote state together they contribute an additional common factor, the com-

binations of these three factors being indispensable for the creation of polydactyly. The polydactyls thus created may produce normal types indefinitely and the normal types produce polydactyls indefinitely—Charles Jung. The calculation of the ureo-secretory coefficient considering the two kidneys separately. The author shows that when the two kidneys work at different concentrations the ureo-secretory coefficient calculated from the total urine is incorrect. He gives an example where the error amounts to 13.8 per cent of the whole, calculated by adding the partial yields—A Schidlof and H Saini. An attempt at a theory of emission of the  $\beta$ -rays by radioactive nuclei. The new interpretation of the authors gives an explanation of the analogy which exists between the  $\alpha$ -rays and the  $\beta$ -rays, and makes clear the cause of the difference between the two classes of radiations—P Dive and R Wavre. The Newtonian potential and multiform functions. The authors show in a very curious example the precautions which should be taken when prolonging analytically an ordinary potential, according to the nature of the topological data—Léon Collet and Ed Paréjas. Results of the geological expedition of Harvard University in the Canadian Rockies (Jasper National Park), 1929. (4) The geological section along Mural Glacier and the thrust plane of the Mumm Peak nappe. The authors give the detailed succession of the terranes along Mural Glacier and determine the thrust plane of the Mumm Peak nappe on both sides of the glacier. Owing to this overthrust, Lower Cambrian with *Olenellus* overrides Upper Cambrian—(5) The geological section between Mount Robson and Moose Pass. The authors present the first complete geological section between Mount Robson and Moose Pass. On this section the thrust plane of the Mumm Peak nappe passes between the Chetang Ridge and the Tate Ridge. Few corrections have to be made to Walcott's section of Mount Robson.

## WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, 18, No 1, Jan 15)—Charles P Winsor. The Gompertz curve as a growth curve. Benjamin Gompertz's curve (*Phil Trans.*, 1825) is compared with the logistic curve, the former seems to give a good fit with material showing an inflection when about 37 per cent of total growth is completed, whereas the latter has its point of inflection about midway between the asymptotes—Wilder D Bancroft, Robert S Gutsell, and John E Rutzler, jr. Reversible coagulation in living tissue. (10) Morphine was withdrawn gradually from a drug addict of long-standing, giving large doses of sodium rhodanate. There were no major withdrawal symptoms. The sodium salt rapidly peptises protein colloids agglomerated by morphine, and also seems to assist in eliminating morphine from the tissue—Harlow Shapley, Ernst J Opik, and Samuel L Boothroyd. The Arizona expedition for the study of meteors. The equipment consists of two huts, on the opposite slopes of the roofs of which are iron reticules to provide co-ordinates of reference for visual observations. The huts are 23 miles apart on an east-west line. Telescopic observations are being made at two stations 2 miles apart. Angular velocities are being observed by a 'double-pendulum apparatus' consisting of an oscillating plate-glass mirror—Howard Sprague Reed. The growth of *Scenedesmus acutus*. Growth of this alga followed the sigmoid curve of autocatalysis except for an initial lag—H E Dolk and K V Thimann. Studies on the growth hormone of plants. (1) The technique of preparing this hormone in quantity from mold cultures is described. Its activity was tested on the

coleoptiles of oats and a unit is suggested. The hormone appears to be an acid which is readily oxidised. A method of purification is described.—Warren W. Wilcox. The basis of the dependence of visual acuity on illumination. Acuity was measured by observing the separation of two parallel bars. For bright bars on a dark ground, acuity first falls with increased illumination, passes through a minimum and then rises. For dark bars on a bright background, acuity decreases with increasing illumination, the rate of decrease becoming progressively less. It is concluded that irradiation, or apparent shift of contours, is the only cause of the variations of visual acuity with intensity. Hecht's theory of a variation in the number of functional retinal elements is unnecessary.—Henry Margenau. Quantum dynamical correction for the equation of state of real gases. London has suggested that the deviations of light gases such as hydrogen and helium from the perfect gas law may be due to the existence of zero point energy associated with the vibratory motion of molecules in quantised collision states rendering the attractive Van der Waals' forces partially ineffective. This problem is investigated quantitatively.—William Duane. New lines in the K-series of X-rays.—Hassler Whitney. Note on Perron's solution of the Dirichlet problem.—J. v. Neumann. Proof of the quasi-ergodic hypothesis.—Jesse Douglas. Seven theorems in the problem of Plateau.—A. W. Tucker. On combinatorial topology.—W. Seidel and S. B. Littauer. Lines of Julia of integral functions.—Eberhard Hopf. On the time average theorem in dynamics.—G. A. Miller. Sets of distinct group operators involving all the products but not all the squares.—Tracy Yerkles Thomas. Conformal tensors (I).—D. V. Widder. On the changes of sign of the derivatives of a function defined by a Laplace integral.—Arthur L. Fox. The relationship between chemical constitution and taste. Phenyl thio carbamide and related substances are bitter in taste to some people and not to others. The taste of these compounds is associated with a C=S linkage (see also NATURE, 128, 124, July 18, 1931).—Albert F. Blakeslee. Genetics of sensory thresholds: taste for phenyl thio carbamide. Inability to taste this compound is inherited as a Mendelian recessive. From experiments using different strengths of solutions, it was found that innate differences exist as regards threshold value, the strength of the sensory reactions, and the ability to detect differences of concentration and to discriminate between different substances.—Harold H. Plough. Elimination of self-sterility in the *Styela* egg—a reinterpretation with further experiments. The author stated in an earlier paper that self-sterility was eliminated due to the addition of ammonia or caustic soda to sea-water containing the eggs. This is incorrect, the effective factor is time. On standing in sea-water, eggs and sperm undergo a spontaneous change which removes the block to self-fertilisation.—T. Cunliffe Barnes. The physiological effect of trihydrol in water. Water containing large quantities of the trihydrol form of water causes much increased rate of growth of *Spargyr*, it is suggested that the colloidal trihydrol aggregates are the first steps in the formation of carbohydrates (see also NATURE, 129, 691, May 7, 1932).

## VIENNA

Academy of Sciences, Jan. 28.—Otto Porsch. The bat-flower problem. A number of species are added to the list of flowers fertilised by bats.—Adolf Franke, Alfred Kroupa, and Theodora Panzer. Ring contraction in the formation of internal ethers (oxides) from glycols. In continuation of the investigation of the action of sulphuric acid on higher glycols, it is found that tetradecan-1, 14-diol also yields an internal

ether, 1, 5-oxidotetradecane.—Robert Sandri. Diffusion and transport of gases in liquids. (2) Diffusion of hydrogen through colloidal and liquid membranes. When a narrow gas-filled tube is closed at one end with a long drop of water and at the other with a thin membrane (rubber), diffusion of the gas and air through the membrane forces the water in one direction or the other. Quantitative investigation of this phenomenon yields results in approximate agreement with Fick's theory of diffusion and with Henry's law.—Wilhelm Petraschek. Comparative studies of deposits—the magnesites and siderites of the Alps.—Alexander Tornquist. An ore-deposit of the Raibl-Bleiberg type in the Dolomites.—Leopold Kolbl. The north-east end of the Grossvenedig mountain group.—K. Graff. Night measurements of the transmissivity coefficients of the atmosphere in Mallorca in winter. Determinations of the transparency coefficient of the atmosphere at night by measuring the brightness of stars at different distances from the zenith yielded surprisingly high values, 23 out of 38 exceeding 0.85, or, allowing for the barometric height, 0.881. These values are distinctly greater than those obtained in Santis and Etna, which are both between 2500 metres and 3000 metres above sea-level.—K. Graff. Distribution of brightness in the sky at full moon. Except in the immediate neighbourhood of the full moon, the relative brightness of the night sky was found to vary only from 1 at the zenith to 0.4 in the polar region.—Michael Radaković. Raman effect. (17) The possible distributions of forces in the mechanical model of a triatomic molecule.—Rudolf Scharfetter. Vegetational relationships of the Gerlitzen in Carinthia.—Viktor Lebzelter. Individual growth in the Koisian race group.—Josef Hoffmann. Behaviour of alkali glasses containing chlorine, fluorine, and sulphate ions, and of manganese glasses, with and without iron, towards  $\beta$ - and  $\gamma$ -radiation. Experimental results confirm the previous conclusion that, with silicate glasses, blue and violet radiation colours are not produced by alkali metal atoms. In manganese glasses, red radiation colours are attributable to Mn ions and violet colours to the simultaneous presence of Mn and Mn ions. The latter alone give no colour, but in combination with iron a grey colour.—Karl Przibram. An empirical rule concerning the behaviour of certain plastic bodies towards pressure.—Stefan Meyer. Proton numbers, atomic numbers, and range of  $\alpha$ -radiators. The range of  $\alpha$ -radiators is given approximately by the expression,  $\log R_0 = \log D + 0.60 - 0.043(P - 223)$ , where  $P$  is the proton number and  $D$  is a function of the atomic number which varies periodically with the cube-root of the reciprocal atomic volume. A property of the nucleus, apparently connected with the periodic behaviour of the shell electrons, is also deduced.

Feb. 4.—Anton Schedler and Max Toperczer. Distribution of the geomagnetic declination in Austria at the epoch 1930.0.—Max Toperczer. The measurement of the magnetic declination with magnets suspended by threads. The corrections rendered necessary in applying this method of measuring magnetic declination, owing to the influence of torsion in combination with the imperfect character of the suspension, are considered. Measurements with two magnets being only just sufficient to eliminate the disturbing influences, the use of a greater number (at least three) of magnets is proposed.—A. Dadiou, K. W. F. Kohlrausch, and A. Pongratz. Studies on the Raman effect. (18) Raman spectrum of organic substances (polysubstituted benzenes). (1) Experiments with the six isomeric xylydines and xylenols show that the spectral type is determined by the position of the substituents and not by their nature. The spectra

may be classified in three groups according to the positions of the radicles introduced (1) symmetrical, 1 3 5, (2) vicinal, 1 2 6 or 1 2 3, and (3) unsymmetrical. Only in case (1) does the principal benzene line ( $\Delta\nu=990$ ) appear with marked intensity, and as the symmetry of the nucleus vibration with the 1 3 5-compound can be only trigonal, it is concluded that the symmetry of the ring itself is also trigonal—Alfred Brukl and Bruno Hahn. The heteropoly-acids of germanium.

### Forthcoming Events

#### FRIDAY, MAY 13

- ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee), at 5 30—J H Driberg Economic Stages of Development in Africa  
 ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30—Annual General Meeting  
 BRITISH ASSOCIATION OF CHEMISTS (London Section) (at Broad Street Station Restaurant, E C), at 7—Annual General Meeting  
 INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at Cowdray Hall, Aberdeen), at 7 30—Prof J K Catterson-Smith Everyday Uses of Electricity (Faraday Lecture)  
 ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir John C W Reith Broadcasting  
 INTERNATIONAL COMMITTEE ON THE HISTORY OF SCIENCE (at Paris) (continued on May 14 to 16)

#### SATURDAY, MAY 14

- ASSOCIATION OF TEACHERS IN TECHNICAL INSTITUTIONS (Annual Conference) (at Technical College, Cardiff) (continued on May 15 to 17)

#### TUESDAY, MAY 17

- ROYAL SOCIETY OF MEDICINE, at 5—Special Meeting of Fellows  
 KING'S COLLEGE, LONDON, at 5 30—Prof M Schlick Form and Content (Succeeding Lectures on May 18 and 20)  
 IRON AND STEEL INSTITUTE (Additional Meeting) (at Royal Metal Exchange, Swansea), at 6—Presentation of Papers

#### WEDNESDAY, MAY 18

- NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (at London School of Economics), at 5 30—Dr C S Myers Psychological and Social Factors in Business Rationalisation (3) The Advantages of Rationalisation  
 INSTITUTION OF WATER ENGINEERS (at Sheffield)—Summer General Meeting (continued at Buxton, May 19 to 21)

#### THURSDAY, MAY 19

- UNIVERSITY COLLEGE, at 2 30—Sir Flinders Petrie Canaanite Civilisation (to be repeated on May 21, at 3, and on May 24, at 5 30)  
 LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5—Prof H Levy A Numerical Study of Differential Equations (Lecture)  
 ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5—Annual General Meeting  
 LIVERPOOL BIOLOGICAL SOCIETY (in Zoology Department, Liverpool University), at 5 30—Mrs C S Hodson Biological Advances and Eugenics (Lecture)  
 UNIVERSITY COLLEGE, at 5 30—Dr C S Myers The Absurdity of any Mind-Body Relation (Hobhouse Memorial Lecture)  
 CHEMICAL SOCIETY, at 8—Discussion on Some Aspects of Asymmetric Synthesis  
 ROYAL SOCIETY OF MEDICINE (Neurology Section), at 8—Annual General Meeting  
 BRITISH INSTITUTE OF RADIOLOGY (Annual General Meeting), at 8—Dr J C Mottram On the Relationship of Beta and Gamma Radiation in the Treatment of Tumours, The Action of Radium on Blood Supply—The White Reaction

GERMAN OPHTHALMOLOGICAL SOCIETY (at Leipzig) (continued on May 20 and 21)

CONGRESS OF INTERNATIONAL ASSOCIATION FOR BRIDGE AND STRUCTURAL ENGINEERING (at Paris) (continued on May 20 to 25)

#### FRIDAY, MAY 20

- ROYAL SOCIETY OF MEDICINE (Physical Medicine Section), at 5 30—Annual General Meeting  
 ROYAL SOCIETY OF MEDICINE (Radiology Section), at 8 30—Annual General Meeting  
 ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof H E Armstrong Faraday at the Sign of the Hexagon Coal Colour and Constitution  
 INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Sedbury, Monmouthshire)—Summer Meeting (continued on May 21 to 23)

#### SATURDAY, MAY 21

- INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7 45—Annual General Meeting  
 GERMAN CONGRESS FOR PSYCHICAL HYGIENE (at Bonn)

## Co-ordination of Government Grants for Research and Development

THE War brought about a recognition of the value and application of research in solving the many problems which arose during the continuance of the struggle. As is well known, Germany, both in government and commercial circles, had recognised the value of research work before the dawn of the present century. The years following the Armistice have furnished evidence that if the British Empire is to keep pace with its competitors it must make the fullest use of the scientific worker in dealing with the complicated questions of administration and development which confront it. It is of good augury that this fact is now appreciated both by the Government of Great Britain and those responsible for the Empire overseas, the subject having been discussed at the Conferences of Prime Ministers which have been held in London.

Omitting for the moment the wider issues of this matter, a brief survey may be made of the developments which have taken place in Great Britain. As a forerunner of newer bodies at present in existence here, the Development Fund was inaugurated in 1910. The objects of this fund were to provide assistance, after due inquiry, to agriculture, fisheries, forestry, and so forth, in the form of grants for education, research, and other development work. After the War other interests arose, some of them conflicting, though this was not appreciated at the time. Bodies such as the Empire Marketing Board, the Colonial Development Fund, and the Colonial and Middle Eastern Services were formed, whilst increased grants for various new purposes were made to the Ministry of Agriculture and to the University Grants Committee.

These newer bodies and the increased activities of the older Development Fund grew up piecemeal, with little co-ordination and in the absence of any carefully thought-out or balanced scheme. To such an extent has this proved the case that many scientific workers themselves have found it difficult to ascertain the proper body to consult in connexion with a piece of work they may have had in hand, whilst to the layman the multiplicity of bodies making grants and the trouble of discovering to which to apply has furnished proof, if proof were wanting, of the inadequacy of the methods in force. Attention was directed to this state of affairs in these columns so long ago as July 26, 1930.

Owing to the lack of unified control over the allocation of grants by the various bodies in existence, it became apparent that Parliament had very little voice in the matter. It was being asked by different bodies to make provision for carrying out objects which were seemingly substantially the same, though this was not evident in the Estimates presented to the House of Commons, nor was it easy to appreciate the position after a close study. For these reasons the matter has been investigated by the Estimates Committee of the House, of which Sir Vivian Henderson is chairman. The first report of this Committee has now been presented to Parliament, and was referred to in *NATURE* of April 16, p. 572. The Committee has confined itself to an examination of the estimates of the above-mentioned funds and services. The report is timely and will prove illuminating to the public, though it may present few surprises to those conversant with the position.

It has been difficult for research workers and others to discover in how far the various bodies receiving grants from Government have been cognisant with the work being undertaken by their confrères, but the Committee does not suggest that the bodies and departments allotting grants are in ignorance of the position. Nevertheless, the Committee has discovered that grants are being made by the Empire Marketing Board for many purposes which are also assisted by the Department of Scientific and Industrial Research, the Ministry of Agriculture, the Development Fund, and the Forestry Commission. Many institutions are receiving grants from the State through one or more, or even up to five or more, different sources. It is also apparent that grants are being made from the Colonial Development Fund for ordinary purposes of government in Colonies which are at the same time in receipt of a grant-in-aid from the Colonial Office. It has thus become apparent (1) that Parliament is not in a position to ascertain with ease the total assistance it is granting to one institution, (2) that the multiplicity of grants obtained by one institution from several different bodies results in a greater total being given than would be the case if the total sum were voted by Parliament itself in a single grant.

The Committee directs attention to the long-established canon of sound finance by which all government aid for any one purpose or any one body should be provided in a single grant. It is recognised that this ideal may often be unattainable; but the Committee considers that it is

essential, before this principle is departed from in any one case, to make sure that there are adequate grounds for so doing.

The Committee is therefore of opinion that, even if bodies and departments have extant elaborate arrangements for maintaining the essential co-ordination, the necessity for such arrangements appears to challenge the efficiency of the present system and to constitute a strong case for reviewing it. It therefore recommends that the Estimates should be so framed in future that the total State grant allocated to any institution should be readily ascertainable.

The authors of the report have expressed no opinion on the policy of assisting the various objects for which grants are made, but they are of opinion that they may properly review the very complicated machinery by which that policy is being carried into effect. Various political and Empire questions, including the adoption of a general tariff and the approaching Ottawa Conference, which need not be entered into here, have come to the front to make the moment opportune for this review. The tariff and Empire preferences, for example, alter the basis upon which the Empire Marketing Board was formed in 1926, and the working of the Colonial Development Fund can now be reviewed in the light of experience which has been gained.

The Committee directs attention to the three-fold organisation for medical, agricultural, and industrial research, under the Lord President of the Council, now taking shape in Great Britain, its suggestion that these bodies should gradually become the controlling departments in their respective spheres will be welcomed.

In the event of effect being given to the Committee's suggestions, the new Advisory Council for Agricultural Research could take over portions of the work of the Development Fund, whilst certain of the work of the Empire Marketing Board might be absorbed by the relevant trade intelligence service. The grants from the Colonial Development Fund should be restricted, as was originally intended, to works of a capital nature, and grants such as have been recently sanctioned for ordinary government administrative purposes should be discontinued.

As regards the inter-relation and co-ordination of grants by the different Empire administrations, the Committee's report should enable this important side of the problem to be discussed with an added insight at the Ottawa Conference to be held in July.

"Let it be granted —That a controversy may be raised about any question and at any distance from that question"—LEWIS CARROLL

"The human mind has compressed ages into a few years for the acquisition of steel-made claws . . . The new organs that to-day are being added as a supplement to Man's vital stock are too quick and too numerous for his inner nature to develop its own simultaneous concordance with them and thus we see everywhere innumerable schoolboys in human society playing pranks with their own and other people's lives and welfare, by means of newly acquired pen-knives which have not had time to become humanized"—RABINDRANATH TAGORE

WE of the body scientific are seeking to impose ourselves mentally upon the world—to rival the word painters—having long done so in ways mechanical and succeeded with terrible effect in part yet with much benefit in some fields. The money-changers have recognised our value by supplying us with capital but we have in no way learnt to curb the control they exercise upon society. To-day, apparently they hold us at ransom. We have the temerity to believe that the public health cannot be sound unless we intervene in its protection and even direct the lines of action. What then is our medical value, primarily, to society, our qualification to advise? To answer the question, we need to hold up the mirror very closely to ourselves—to ask what we see in ourselves that is special, what we ought to ask for, what we should find. To see more than darkly is very difficult—as years go by the field of view is ever widening, the need of grasping the whole field more obvious, the vision more and more clouded, less easy to interpret. We can but compare—nothing is absolute—through biography especially not necessarily through study of special books but constantly of thumb-nail sketches to be made here and there, indeed everywhere.

I have long advisedly watched the game we play and often asked myself what its meaning was, how it might be directed and brought under rule, so as to be of more avail than it is. No general answer is forthcoming. I entered upon my career as a

student thirsting for knowledge of method. My first books—"Pepper's Playbook of Science" in particular—had told me of much that was interesting but nothing of the process by which the knowledge had been gained. How could one learn to do such things? I found the teaching dogmatic—Huxley's especially—but much of it was practical and went home. Gradually, in Germany particularly, the method in the background began to leak through, so that I was able to build outlines of a system.

When I began to teach, in 1870, I already had a conscious purpose and desire—to aid in introducing what Charles Kingsley had so aptly termed the method of sound scientific thought. We were then at the Darwin-Colenso stage—faith was giving way to fact. We began by fighting down the cramping system of payment by results administered by Matthew Arnold and others, more freedom of thought seemed to prevail but only during a brief interval. In stealthy ways, first through the inspector, the examiners have not only recovered their position but also have raised their dread power to that of inquisitioners. We are fallen back into the paths of primitive religion. unquestioning faith, not eternal doubt, is the demand now made upon the student. There's not to reason why, there's but to do and die. Were it not for a few pathfinders, our so-called science would be entirely romanised in its methods—this is why it is proving to be of so little public worth in lifting the masses into intelligence. The sale of moral filth is being consistently cheapened. No considered effort is being made, from our side, to meet what desire there may be for healthy knowledge. A transcendent future and the inwards of atoms are held out for popular consumption, the present doings of the hordes of earthly molecules remain unnoticed. We make no attempt to get down to any understanding of life as it is. The talk is all of the past—which we study but do not heed. Whence springs the new discipline of science? What is there in ourselves from which it is bred? It is in some way a natural product but of rare occurrence. Is this accident or inevitable?

The point of view from which I would consider the biography of Sir Edmund Gosse will be apparent from these remarks. He died in May 1928. A critic and literary publicist of some distinction, much given to the study of current French literature, librarian to the House of Lords, 1904–14, he was best known in his last years on account of the felicitous weekly literary article which he contributed to the *Sunday Times*, after he left the

Lords The one work which won him distinction was his "Father and Son" (1907)—an intimate account of his most remarkable father and mother and of his own early upbringing under their affectionate but severe guidance. As a biography the book now ranks as a classic, of great historical and psychological value. I read it with intense interest when it was first published. Although issued anonymously, it was easy to guess who father and son were—"Goose and Gosling", you mean", at once said the late Israel Zangwill, when asked if he had read the book.

The father—Philip Henry Gosse (1810–87)—was a zoologist of repute, a fellow of the Royal Society, to which he contributed no less than sixty-two descriptive papers. Brought up in a severely puritan atmosphere, he early developed great natural aptitude as botanist and zoologist, at the same time he became intensely religious and eventually a member of the Plymouth Brotherhood, a sect closely akin to the Sandemanians, to which Faraday belonged. He wrote a number of popular natural history books, which he himself illustrated. His father, although a painter, was an indefatigable writer. Philip Gosse married Emily Bowles, who was of New England descent, she was a successful writer of tracts. In her son's opinion, she had in her the making of a novelist but advisedly abstained from writing, being naturally of a very devout and pious turn of mind. She had formed a definite conception of the absolute, unmodified and historical veracity, in its direct and obvious sense, of every statement contained within the covers of the Bible.

Edmund Gosse, therefore, had a strong infusion of literary blood in him, hence we can understand how it was that he became a victim of what his grandmother called—that cursed writin'.

The turning point in Philip Gosse's career came when Darwin's "Origin of Species" divided the ranks of naturalists. Gosse appears to have been privately advised of the theory in advance by Hooker, Darwin and Lyell, with the view of joining in its support. As a naturalist he was at first inclined to favour it but soon reverted to the first chapter of Genesis—he forthwith wrote, as a challenge, in advance, his celebrated "*Omphalos*" (1857)—an attempt to untie the geological knot.<sup>1</sup> He argued, quite logically, that an all-important factor had been left out of account—'the Law of Prochronism in creation'. He contended that when the catastrophic act took place, the world presented instantaneously the appearance of a planet on which life had long existed, fossils in-

cluded—made to order with all other things. Such was faith—such the power of the Bible in days before Darwin.

We may think him narrow but taking the state of opinion into account, Gosse's mental attitude, I venture to think, was in no whit different from that prevailing to-day among students in nearly all branches of science. 'And Arrhenius said—Let there be ions and there were ions', is as firmly believed in by the majority as any fiat in the first chapter of Genesis was by Gosse. Our general mental reactions are the same as they were—we still worship authority, only some have changed their book and have new gods. The point is—Gosse had a closed mind so have most of us. Darwin still has few supporters, prepared not merely to face the facts but demanding suspension of judgment until the case be complete.

The young Huxley scoffed at Gosse's book and Charles Kingsley gave him no support. He became a mental wreck through disappointment and was no more seen at the Royal Society. To the last, he remained in expectation of the personal coming of the Lord. His son's biographer writes—"his faith, being cast in bronze and unassailable, did not suffer but his dogmatism grew less vociferous, a new gentleness tempered his outlook towards the opinions of others and blent with his affection for his son."

How is such a man to be classed? Not among scientific thinkers. He was contemporary with Carlyle, Charles Kingsley and Ruskin. These men were all literary and greatly devoted to the Bible, all greatly influenced by its teachings but without Gosse's bigotry. Ruskin was the most fully imbued with its spirit and saturated with its language, he was also a naturalist, a geologist of no mean order, as an art worker he was exceptionally exact and scientific, yet a rhapsodist and unscientific in general outlook. Carlyle was the rigid scholar in outlook but dour in spirit and interests. Kingsley was the hearty, sporting country clergyman, supercharged with energy, a good pen and imbued with a clear conception of scientific method. At one time he was overcome by doubts, even Ruskin confessed, in late life, to the feeling that he might have been led to change his views had he dared to reconsider their validity.

Edmund Gosse was not only different from his father but seems also to have been little influenced mentally by his severe training at the hands of his parents. He did not even assimilate biblical English. He early became emancipated in a re-

markable way When about six years old, he lost his belief in his father's omniscience by discovering that his statements about things in general could not be implicitly accepted Then he began to question the efficacy of prayer, to which absolute value was attached by his parents, when told that he must not pray for things, although the view held by the household was that if anything were desired you should not lose any time in seeking for it but ask God to guide you to it

Finally, when idolatry was severely condemned at mission meetings, particularly bowing down before wood and stone, he decided to make an experiment hoisting a small chair on to the table close to the window, he said his daily prayer in a loud voice, substituting the address "O Chair" for the usual one He expected that God would certainly exhibit his anger and chastise his impious and wilful action Nothing happened His conclusion was that his father was not really acquainted with the divine practice in cases of idolatry What might have happened had such a thinking child been taught properly to experiment and reason? I commend the problem to the attention of Dr Lyttelton

His father trained Edmund Gosse so thoroughly as an observer and collector of marine organisms that, before he was five years old, the boy discovered 'a tiny atom', which he carried to his father as a form 'with which he was unacquainted', since figured on lists of sea-anemones as *Phellia macrocinela* or the walled corklet The training, however, had no effect in leading him to take up such study One lesson he had from his father, in about his fourth year, is worthy of notice, we may even say, 'Teachers, please copy'

"In particular, he had a scheme for rationalising geography, which I think was admirable I was to climb upon a chair, while, standing at my side, with a pencil and a sheet of paper, he was to draw a chart of the markings on the carpet Then, when I understood the system, another chart on a smaller scale of the furniture in the room, then of a floor of the house, then of the back-garden, then of a section of the street The result of this was that geography came to me of itself, as a perfectly natural miniature arrangement of objects and, to this day, has always been the science which gives me least difficulty"

Edmund Gosse became emancipated when he came to London at the age of seventeen Through the influence of Charles Kingsley, he found an opening at the British Museum in the cataloguing section. Thereafter he reverted to his type and became a mere man of words, showing no particu-

lar interests outside humanistic literature. The "Life and Letters" contains many of his letters but there is little in these of interest or in any special way informative that a father and mother of ultra-rigid outlook should give rise to a son, if not of loose opinions, of no opinion in particular about any subject yet with some gift of words, is very remarkable The story is of value in connexion with the present attempt to produce biologists—can men worth their salt be nursed into being by any education? I doubt it

Man to the chemist is a composite structure of organic compounds—life the interaction of molecular forces Outside this definition we cannot go—nor do we see how those who cannot think in terms of chemistry have the right to go further either in assertion or denial In the laboratory the possibilities are infinite, in ourselves they are limited—we are built, it seems, to pattern, of selected oriented materials, our operations are as strictly controlled as if we ran upon roads and rails Nature, the dear old nurse, has so taken us by the hand that she regulates our actions by drugs—nerves seem to be only of secondary value, conductors of impulses and orders We are bedrugged not only from within but also from without—by an astounding set of 'factors' which are gradually being dragged into the open, as definite crystalline substances The outlook grows more and more 'mechanised' every day

"That which merely gives us information can be explained in terms of measurement but that which gives us joy cannot be explained by the facts of a mere grouping of atoms and molecules", says the poet Rabindranath Tagore What of the "joy" that is to be obtained by merely pricking a little morphine into the blood stream? I would range all the controlling agents under the name advitants—endogenous or exogenous They are all carbon compounds, some of simple, some of complex structure Whatever their mode of action, it certainly is the outcome of peculiarities in their structure From this point of view, the various types of mentality are due to variations in the structure of our own composite mechanism

One type is necessarily dominant—the literary So soon as man rose in numbers, words gained control and the wordy perpetuated their kind, the while doing the minimum of manual work To write is but to talk upon paper To maintain society subservience became necessary The able came together but kept themselves under, through jealousy. the adventurous naturally often fell victims. Only the few could be allowed to think

To-day we are advisedly limiting their number by declining to breed them. Hence the present state of society—and it may become far worse.

The industrial element has been gradually developed through the rise of intelligent men from the working masses. This class alone has encouraged invention and experimental inquiry. The literary class has parasitically enjoyed the fruits of the work of the industrial class, without ever entering into its methods. At all times, the commercial instinct must have been more or less developed in all men, as man is necessarily individual. No communistic experiment such as the Russians are seeking to make has hitherto been successful. It is easy to see how a merchant class is arisen and, with its power of the purse, has assumed control in modern industry without sufficiently understanding what it controls.

It is clear that, in the future, divided control—involving the inclusion of all necessary elements—can alone give what is needed. The German industrialists have already proved this to demonstration. They have also already found that it is easy to go too far. Recent events also show how, in matters of government, it is being recognised that expert aid is essential to success. We are on the way to recognise that the introduction of scientific method into our affairs cannot much longer be avoided. The attitude of ultra-conservatives like Lord Snowden and Sir Herbert Samuel is of extraordinary interest, showing their complete inability to interpret the changes introduced into the world at the hands of workers in natural science, as distinct from humanistic science. The Realists must have it in the end. It is no longer a question what the masses do: the problem is what the few can and must do to provide occupation, food and lodging for the masses.

"To-day more than ever before in our history, the aid of spiritual power is needed. Its sources will surely be discovered in the hidden depths of our being. Pioneers will come to take up this adventure and suffer and through suffering open out a path to that higher elevation of life in which lies our safety."

"The vastness of the race problem with which we are faced to-day will either compel us to train ourselves to moral fitness in the place of merely external efficiency or the complication arising out of it will fetter all our movements and drive us to our death."

The poet has vision where the scientific worker is unseeing. He preaches a true religion of man—something above research as this is now understood.

HENRY E. ARMSTRONG

### Teaching of Mathematics

- (1) *The Teaching of Arithmetic in Schools: a Report prepared for the Mathematical Association*. Pp 82. (London: G. Bell and Sons, Ltd., 1932.) 2s net.
- (2) *The Teaching of Elementary Algebra*. By Clement V. Durell. Pp viii + 136. (London: G. Bell and Sons, Ltd., 1931.) 3s 6d net.

NOT only is the science of mathematics constantly pushing forward its boundaries, but the old territory is also being examined afresh, and new methods of approach are being suggested and tried. Of this latter fact the two little books under review afford clear evidence.

(1) The first, which deals with the teaching of fundamentals, is issued by the Mathematical Association, and it is difficult to overrate the influence exerted by this Association on the teaching in secondary schools. It has already introduced reforms, notably in subtraction and multiplication, which, though they may seem trifling when viewed by themselves, profoundly affect the work in the more advanced stages. This new Report suggests no startling innovations, but it stands as a compendium of the most enlightened methods practised in our schools to-day. It advocates uniformity of method, so far as that is practicable, within the same school, but it gives a number of different methods without dogmatising about their relative values. It is quite definite however, in its recommendations, and it shows commendable courage in modifying its previous recommendations where they have not stood the test of practical experience in the classroom.

(2) Mr Durell's book, representing as it does the opinions of one man, belongs to a different category. Its teachings are more open to controversy. It expounds with great lucidity the views of the modern school, views which the present reviewer regards as essentially sound. In the days of his youth, Todhunter and Colenso wrote the authoritative textbooks in algebra. They set a fashion, or rather perpetuated a fashion, which is largely followed up to the present day. The defects of the tradition are many. One is that it introduces algebra as a new subject, and not as a natural development of the science of number which the pupils have previously been studying. Another is that it attaches undue importance to the manipulation of symbols as distinct from an understanding of their significance. A third is that it ignores the fundamental distinction between directed and non-directed numbers, a distinction which was first brought out prominently in England in Sir Percy

Nunn's epoch-making book. The intelligent student of the olden days used to feel vaguely that the signs + and - were used ambiguously, that they were sometimes used as verbs and meant *add* or *subtract*, and sometimes as adjectives, and defined the number that followed as *positive* or *negative*. But the distinction was never brought out clearly in the text-books.

The new school of algebra teachers, of whom Mr Durell is a good representative, has changed all that. It has made the clear comprehension of what directed numbers mean one of the essential aims in the teaching of algebra, and it has so devised the approach to the study of algebra that the gulf between it and arithmetic should disappear. There is a difference of opinion whether that approach should be via the equation, or via the formulæ that are used in mensuration and in science. Mr Durell favours the latter, and gives very cogent arguments for his preference. He writes well, seasons his theories with an abundance of common sense, and presents the reader with valuable hints on teaching which are based on a wide personal experience. P. B. BALLARD

### Systematic Zoology

*Klassen und Ordnungen des Tierreichs, wissenschaftlich dargestellt in Wort und Bild.* Von Dr. H. G. Bronn. (1) Band 3, Abteilung 3 *Bivalvia* (*Muscheln*). Bearbeitet von Dr. F. Haas. Lief. 1. Pp. 176. 1950 gold marks. Lief. 2. *Schriftenverzeichnis*. Pp. 292. 38 gold marks. Lief. 3. Pp. 177-384. 28.80 gold marks. (2) Band 4 *Vermes*. Abteilung 2 *Aschelminthen*. Buch 1. *Rotatorien, Gastrotrichen und Kino-rhynchen*. Bearbeitet von A. Remane. Lief. 1. *Rotatorien*. Pp. 160. 20 gold marks. (Leipzig. Akademische Verlagsgesellschaft m. b. H., 1929-1931.)

(1) **O**F the three parts of this new account of the bivalve molluscs, one (the second section) is entirely occupied by an alphabetical list of almost 7000 titles of books and papers on the class published up to the end of 1928. The author promises a further list of more recent works when the text is finally completed. This account of the bivalves is planned on a liberal scale, for the two parts of the text before us, altogether 384 pages, carry the description only so far as the shell and the cognate subject of pearls. The characters and classification of the *Bivalvia* are briefly set forth; three main orders are recognised—Ansomylaria, Taxodontia, and Eulamellibranchiata, the last

divided into five sub-orders. A short account of the form, relations, and positions of the organs prefaces the detailed consideration of the shell, which begins with the description of the varied external features and the mathematics of the curvature of the shell-valves.

The author has given very adequate attention to the sculpture and colouring of the shell surface, the structure and chemical composition of the component layers of the shell, the interlocking mechanisms and the ligament, and the sexual dimorphism exhibited by the shells of a number of species which have been described under different names for the two sexes. The last eighty pages, devoted to a description of the different kinds of pearls and their modes of formation, form a useful summary of present knowledge of this subject. The text is illustrated by 200 clearly drawn figures. We look forward to an equally adequate account of the soft parts.

(2) The Rotifers are usually regarded as 'a small group', but the number of species known is stated to be more than 900, and the number of species living is probably not less than 1500. The literature is extensive—the author states that a list of the published papers will occupy almost 100 pages—and is widely scattered, and therefore a new account of the group by an author so competent will be welcomed by professional and by amateur workers. Both of these will regret some of the changes in nomenclature, for example, *Epiphanes* instead of *Hydatina*, *Floscularia* for *Melicerta*, which appear to be necessary if the double nomenclature employed for certain genera since 1913 is to be avoided. A statement of the characters of the Rotifera is accompanied by six useful original drawings showing the anatomical features as seen from dorsal, ventral, and lateral aspects. This is followed by an excellent account of the history of our knowledge of the Rotifera which, apart from a note by John Harris (1696), begins with Leeuwenhoek's descriptions of some of these animals, among which the well-known *Melicerta ringens* (or, as it is to be called, *Floscularia ringens*) is clearly recognisable.

The historical section is divided into four periods—the first from 1696, the second from 1838, when Ehrenberg's well-known work on Infusoria appeared, the third from the time of publication of Hudson and Gosse's monograph in 1886, and the fourth from Beauchamp's memoir in 1909. In a brief statement on the size of Rotifers, the author remarks that the smallest, *Ascomorpha minima*, which is about 0.04 mm long and 0.03 mm broad,

is the smallest known metazoan. The different forms of the body of Rotifers, the jointing of the body, the head and its corona and processes, the appendages of the trunk, and the foot are considered. The ciliation of the trochal region is traced from the primitive type, most closely approximated in *Notommata*, through the varying forms represented by *Pedalia*, *Floscularia* (*Melicerata*), *Philodina*, *Epiphanes* (*Hydatina*), and *Brachionus*, and a description is added of the wheel-organs of each family.

A clear account is given of the glands, including the retrocerebral organ, the different grades of development of the lorica, and the three kinds of envelope—the gelatinous, as in certain *Flosculariacea*, the secreted case of firmer consistency, as in the Bdelloid genus *Habrotrocha*, and the envelope formed of foreign particles, as in *Floscularia ringens*. The illustrations, 153 in number, are well chosen and clearly reproduced.

### Short Reviews

*Das Tierreich eine Zusammenstellung und Kennzeichnung der rezenten Tierformen*. Gegründet von der Deutschen Zoologischen Gesellschaft. Im Auftrage der Preussischen Akademie der Wissenschaften zu Berlin. Herausgegeben von F. E. Schulze and W. Kukenthal.

- (1) Lief. 54 *Myriapoda 2 Scolopendromorpha*. Bearbeitet von Dr. Graf Attems. Pp. xix + 308. 50 gold marks.
- (2) Lief. 55 *Amphibia Anura III., Polypedatidae*. Bearbeitet von Dr. E. Ahl. Pp. xvi + 477. 77 50 gold marks.
- (3) Lief. 56 *Acarina, Bdellidae, Nicolettiellidae, Cryptognathidae*. Bearbeitet von Dr. Sig. Thor. Pp. xiii + 87. n.p. (Berlin und Leipzig: Walter de Gruyter und Co., 1931.)

(1) DR. GRAF ATTEMS gives a brief account (16 pp.) of the external morphology of the Scolopendromorpha and defines the two families, Scolopendridae and Cryptopidae, which constitute the order. In the first of these families are 16 genera with 238 recognised species, besides a further 44 species of uncertain position; in the second family are 12 genera with 106 species, with a score which are incompletely described. The discrimination of genera and species is made as straightforward as possible by the provision of excellent keys and of clearly drawn illustrations, 387 in number.

(2) A brief description of the salient biological and structural features of these tree frogs precedes the systematic account of the twelve genera and 527 species—found in the African and Indo-Malayan region—which are included in the family Polypedatidae. Noteworthy are the keys devised for the separation of the large genera *Rhacophorus* and *Hyperolius*, each of which contains nearly two hundred species. The systematic characters are

set forth clearly, and for many of the species in considerable detail, and there are 320 figures, mostly in half-tone, representing usually the dorsal aspect of the frogs.

(3) The systematic treatment of the Bdellidae or snouted mites is prefaced by a useful account of their external features, internal anatomy, life history, and biology. For the less-known Nicolettiellidae a briefer description suffices, and for the very small Cryptognathidae, with only one genus and two species, the general account is restricted to the external features, as the development, internal anatomy, and the nature of the food of these mites are unknown. The keys, systematic descriptions, and illustrations have been carefully prepared by Dr. Sig. Thor, to afford the maximum of help in the difficult task of determining these mites.

Each volume has a systematic index and "nomenclator generum et subgenerum." The three parts before us worthily maintain the high traditions of the series to which they belong.

*Electrical Insulating Materials an Engineering Treatise on the Production, Characteristics and Uses of Electrical Insulating Materials*. By H. Warren. Pp. 516. (London: Ernest Benn, Ltd., 1931.) 42s. net.

THE insulating materials from which the designer has to choose cover a very wide range of natural and artificial substances. They vary from rocky deposits, like slate and marble, to highly complicated synthetic resins. The engineering expert has to familiarise himself with all of them, and choose for his special purposes those with suitable characteristics. Mica is the most important mineral material for insulating work. Its excellent electrical properties, great mechanical strength, ease of cleavage into continuous laminae, purity, chemical inertness, and resistance to high temperature put it into a class by itself. It is used in natural plates for condensers, certain heating devices, and small commutators. It is also used for non-electrical purposes, such as sound-producing diaphragms, and to build up composite materials.

On the other hand, materials like casein, the albuminoid which is the basis of cheese, is sometimes used for switch covers, lampholders, etc., especially abroad. The manufacturer has to consider ease of working and the degree of polish possible, as well as the electrical and mechanical properties of the materials. He will find this book most useful for reference, and parts of it suggestive and instructive.

*Manx Algae: an Algal Survey of the South End of the Isle of Man*. By Dr. Margery Knight and Mary W. Parke. (L.M.B.C. Memoirs on Typical British Marine Plants and Animals, 30.) Pp. vii + 155 + 19 plates. (Liverpool: University Press of Liverpool, London: Hodder and Stoughton, Ltd., 1931.) 10s. 6d.

BRITISH workers in the field of marine algology have been seriously hampered for many years by the paucity of literature. The present memoir is

a welcome addition, being the result of some years of work at the Isle of Man research station. It includes the Chlorophyceæ, Phæophyceæ, and Rhodophyceæ, and embodies the results of a systematic survey of the south-east corner of the island.

The first part of the book gives an account of the way in which the marine algæ perennate, and separates them into perennials, pseudo-perennials, and annuals, basing the categories on the extent of thallus destruction in the autumn and the extent of the growing period. An interesting account is also given of the algal migrations in the littoral zone, careful observation having revealed the fact that the algæ move up and down the shore with a seasonal periodicity that can possibly be correlated with changes in external factors, such as light and temperature. In all cases the onset of unfavourable conditions appears to be heralded by copious reproduction. So little work of this kind has been published that this section of the book will be especially welcomed by algologists.

In addition to this, the authors have compiled a list of algæ for the area concerned, with their precise localities and time of reproduction. They have also constructed a key for the identification of these same genera.

The plates and maps are a useful asset, those of the former, showing the algæ *in situ*, being a particularly pleasing addition to the volume.

L N

*Vergleichende Stammesgeschichte Grundlagen, Methoden, Probleme unter besonderer Berücksichtigung der höheren Krebse*. Von K. Beurlen (Fortschritte der Geologie und Paläontologie, herausgegeben von Prof. Dr. W. Soergel, Band 8, Heft 26). Pp. viii + 317-586. (Berlin: Gebrüder Borntraeger, 1930.) 30 gold marks.

PALÆONTOLOGY, compared with zoology and botany, suffers many disabilities, but these are in part outweighed by one advantage which the sciences concerned with living organisms cannot possess—the time factor. This advantage is particularly evident in studies dealing with the broader aspects of phylogeny. In this present work is given a detailed examination of the phylogeny of the higher Crustacea. Two main periods of development are suggested, outside which no new types have arisen. At these times development was explosive, many new types arising between which no transitional forms are found. The course of development in the many other animal groups briefly analysed by the author appears to be parallel to that given for the Decapoda: each developmental cycle is characterised by two stages, the first in which new types suddenly appear, and the second in which these types undergo continuous modification.

The work concludes with a discussion of many problems and theories of evolution, such as orthogenesis, adaptation, and function and form—"Die Funktion folgt aus der Form." Although the subject matter of the book is thus mainly bio-

logical, yet it appears likely that many of the suggestions contained in it must eventually be approached from the geological side.

*Tara: a Pagan Sanctuary of Ancient Ireland*. By Prof. R. A. S. Macalister. Pp. vi + 208 + 10 plates. (London: Charles Scribner's Sons, 1931.) 10s. 6d. net.

PROF. MACALISTER'S "Tara" is a study in archaeology and traditional history combined such as would be possible nowhere but in Ireland. He takes his readers over the ground of this famous centre of Ireland's history with the "Dindsenchas" in his hand. Point by point the account of Tara given in this 'guide-book' of the ninth century is compared with the site, and it is shown how far the structures mentioned may be identified, or with what degree of certainty the position of others may be conjectured. Prof. Macalister's plea for a scientific investigation of the site is justified repeatedly. It is a work which might well be regarded as a national duty.

Prof. Macalister is on less solid ground when he turns to the unravelling of the traditions connected with Tara. He puts forward the extremely interesting suggestion that it was the centre of a 'Twin' cult, and the sanctuary of a priest-king like the Grove of Nemi, the Irish king being exposed to the same fate of slaughter by a stronger rival as the Italian ministrant of the sacred grove. Prof. Macalister's theories offer material of much interest for discussion, but without much hope of arriving at any certain conclusion on the evidence as it stands at present.

*The Psychology of Children's Drawings from the First Stroke to the Coloured Drawing*. By Helga Eng. Translated by H. Stafford Hatfield. (International Library of Psychology, Philosophy and Scientific Method.) Pp. viii + 223 + 8 plates. (London: Kegan Paul and Co., Ltd., 1931.) 12s. 6d. net.

THE subject of this book is a very fascinating one and deals with the development of children's drawings from the first ill-defined scribbling of the infant through the formalised drawings of older children. The author points out that small children draw not so much what they see as what they know. In the final chapter, there is provided a comparison of children's drawing and the art of primitive man. It is emphasised that so many of the drawings found on cave walls, etc., and attributed to primitive man, are works of art, and could not be produced by any present-day child or adult of average ability. They are the work of the artists of the day. The drawings of children always show a formalism, stiffness, and want of expression seldom seen in the work of primitive man. There is in the work of the ancient artists a representation of expression, of movement, of reality which is not seen in the drawings of children. There is still room for a vast amount of work to be done on the development of children's drawings, their relation to eidetic imagery, to mental development, and the phantasy life of the child.

### The Uncertainty Principle in Modern Physics

SOMEWHERE in the literature of the theory of relativity occurs the statement "The theory of relativity is physics, and we render it no good service by too hastily attributing to it a philosophical or indeed a speculative metaphysical meaning." Prof C G Darwin, in his Friday evening discourse before the Royal Institution on Feb 26, did not quite make the same statement about the uncertainty principle, but he stressed its physical side and had only a word or two to say on its other aspects. Prof Darwin believes that the question of human free will is not touched by recent developments in physics. It is doubtful if any of the old deterministic descriptions of Nature were antagonistic to the doctrine of human free will, for it is a presumption to suppose that the organic world is controlled only by the laws of physics and chemistry. Since the Heisenberg uncertainty relations are also laws of the inorganic world, it is again a presumption to suppose that they control those activities in which human beings feel that they have freedom of choice. What the new principle does is point out to the 'die-hard' determinist that there is nothing in physics which makes the idea of free will absurd.

Prof Darwin's lecture was a very clear exposition of the principle, and those who were not present to hear it will profit by reading the printed version. He gives an excellent illustration of the completely wave-like character of particles. If electrons are shot through two small holes situated close together in a screen, they produce an interference pattern on a photographic plate placed to receive them on the other side. If one hole is covered so that a pin-hole camera results, the electrons passing through the remaining hole produce general fogging of the plate. This is an experiment which can be performed in thought only, it is given as a type and contains the essential point of other practical experiments. It brings out the fact that these showers of particles have more than a particle aspect, they are also waves.

The Heisenberg uncertainty principle is the expression of our inability to locate a particle, for example, an electron, and to measure its momentum accurately at the same time. Heisenberg appears to take the view that processes in Nature are discontinuous. Other exponents of the theory assume that the laws of Nature are average or probability laws. They go so far as to say that the principle of causality no longer holds in the old sense in which that principle was applied.

Another possible conclusion is that the new principle is a consequence of our predilection for the description of phenomena in space-time, and that a wider background than that provided by the four variables  $x$ ,  $y$ ,  $z$ , and  $t$  would make the principle unnecessary. This question and the attempt to discover a unitary method of description in physics are closely associated.

The theory of relativity stresses the lack of union between gravitational and electromagnetic pheno-

mena, and since its advent several attempts have been made to unite these two domains. Weyl, Eddington, and Einstein have all succeeded in doing so, but quantum phenomena stand aside from their theories in the same way that electro-magnetism stood aside from Einstein's theory of gravitation.

Dirac's equations, especially in Darwin's form point to a remarkable analogy between the quantum and electromagnetic theories, and it has been shown that these fundamental equations of the new quantum theory are expressible in the form of a vanishing divergence, when the geometrical background is that afforded by the use of five variables. This at once suggests the possibility of union of all the three domains, and the theory has been successfully developed.

We are here concerned with one result arising from this unitary theory, namely, the fundamental importance of the length  $h/m_0c$ , associated with any particle of mass  $m_0$ .

The theory shows that Planck's assumption of the existence of a quantum of action and the Wilson Sommerfeld relations both lead to the result that no length less than  $h/m_0c$  is detectable in association with the particle.

The principle, stated in a slightly different form has been called the principle of 'minimum proper time'. The length in this case is measured along the track of the particle in space-time. When interpreted in terms of ordinary space and time, it means that in the case of a particle moving with velocity  $v$ , the smallest detectable length is

$$\Delta l = \frac{h}{m_0c} \frac{\beta}{\sqrt{1-\beta^2}} \text{ where } \beta = v/c,$$

and the smallest detectable interval of time is

$$\Delta t = \frac{h}{m_0c} \cdot \frac{1}{\sqrt{1-\beta^2}}.$$

This means that there is always an uncertainty in the position of the particle of amount  $\Delta l$ . The amount increases with the velocity, and if the velocity of light could be attained, it would be impossible to locate it at all. Like a monochromatic wave, it might be said to occupy all space. This principle of uncertainty was also discovered by Ruark in 1928 in a different form and by a different method, but his statement of it is evidently the expression of the same principle. Since that time it has been frequently rediscovered and discussed.

In spite of the fundamental difference between this principle and that of Heisenberg, it can be shown that it leads to his relations when the distances concerned are small. A very interesting result follows from an application to atomic orbits. No atomic orbit can be shorter than  $\Delta l$ , otherwise we could detect its existence through the spectrum of the atom in which it occurs. It follows from this that there is a maximum atomic number, and calculation shows the number to be 97. The prir

ciple admits the possible existence of heavier nuclei, but declares that it is impossible for atoms of higher number, built on the Rutherford model, to exist with their full complement of electrons. If the laws we discover in physics hold in all parts of the universe, we deduce that there is this definite limit to the number of elements existing. This is an interesting conclusion, and it is remarkable that the number falls so close to the number of elements at present known, namely, 92. The principle behaves here as a condition of stability, and it may be that elements of higher number than 92 are extremely unstable, and now remain only in minute quantities.

This question of the maximum number of elements possible has been discussed by V. V. Narlikar in *NATURE* for March 12, p. 402, 1932. The notation and method of Sir Arthur Eddington have been applied, and from considerations of invariance the maximum number obtained is 92.

The unitary theory and uncertainty principle deduced from it indicate that observers in space and time will discover both space and time are discontinuous, for their measurements of intervals of length and time will always be in integral multiples of  $\Delta l$  and  $\Delta t$ . The method of arriving at this conclusion indicates that this discontinuity underlies the old quantum theory.

H. T. FLINT

### Sir Charles Parsons and his Work

"SAVERY, Newcomen, Smeaton, the famous Watt, Woolf, Trevithick, and some other English engineers were the veritable creators of the steam engine," said Sadi Carnot in his essay of 1824, while a year ago the *Engineer*, on the occasion of the death of Sir Charles Parsons, remarked that "to Great Britain belongs the credit for the origination of nearly all the fundamental inventions for the production and industrial utilisation of heat energy."

Although during the nineteenth century many improvements in heat engines, more especially in internal combustion engines, were made abroad, it remains true that it is in the records of the British Patent Office that most of the outstanding inventions made in connexion with steam engines and steam turbines are to be found. With the steam turbine will ever be associated the name of Sir Charles Parsons, who, as Sir Alfred Ewing said when lecturing on the work of Parsons at the Royal Institution last November, "was incomparably the most illustrious and most revolutionary engineer of his time." In view of the long and close friendship of Sir Alfred with Parsons, it was almost inevitable that on the occasion of this lecture, an account of which has recently been published, he should pay a tribute to him not only as an engineer but also as a friend. He therefore addressed his remarks not so much to those familiar with the steam turbine and its development, as to those who wished to know more of what Parsons did and how he did it, and what manner of man he was that he should be ranked so confidently among famous men.

Allowing for differences in time and circumstances, there is a remarkable similarity between the work done by Watt and by Parsons, and what the latter said of his great forerunner might well be applied to himself. When delivering the second Joule memorial lecture to the Manchester Literary and Philosophical Society in 1922, Parsons said: "James Watt's conclusions appear to have been the result of close and patient reasoning of a mind endowed with extraordinary powers of insight into physical questions, and of drawing sound practical conclusions from numerous experiments devised to throw light on the subject under consideration."

In his early surroundings, Parsons was even more

fortunate than Watt, and his boyhood was spent in an atmosphere calculated to stimulate to the highest degree his interest in science and the mechanical arts. His father, by his construction of the famous reflecting telescope, had made Birr Castle the 'Mecca' of astronomers all over the world, while his mother possessed manipulative skill of no mean order. His tutors, too, were men of the highest calibre. In its influence on its various members, the home at Birr may well be compared to that of the Darwins at Downe. From it, Parsons emerged one of the most industrious of men, but also one of the shyest, and the effects of his unconventional boyhood remained stamped on him for life. It was his natural reserve and modesty—characteristics possessed by few inventors—which puzzled strangers. "His hesitating, fragmentary speech, his passive hand-shake, his somewhat shrinking manner," said Sir Alfred, "gave at first an impression of ineffectiveness which completely belied the latent force, the precision of purpose, the resolution that treated obstacles only as incentives to further effort, the fertility of invention that never accepted defeat."

Of Parsons' invention and development of the steam turbine, it may be said it was a piece of creative work comparable to that of a great writer or artist. Moreover, it was one for which the time was ripe, and which immediately and successfully fulfilled its purpose. The slow-speed reciprocating engines developed from the original inventions of Newcomen and Watt were ill adapted for driving the electric generators which were just coming into use when Parsons started work, and he was but one of many who attacked the problem of high speed. De Laval solved it one way and Parsons another. Thanks to the authorities at the Science Museum, Sir Alfred was able to exhibit at his lecture the historic turbo-generator Parsons made in 1884 and exhibited in the Inventions Exhibition of 1885. Running at the extraordinary speed of 18,000 revolutions a minute, the turbine drove an armature of only 2½ in. diameter, the construction of which displayed as much ingenuity as the turbine itself. It was not mentioned by Sir Alfred, and it is little known, that among the important novelties in this machine was a system of forced lubrication.

At first the Parsons turbine was used without a condenser and was "a notorious steam eater". How Parsons brought in the compound turbine, the condensing turbine, the marine turbine, and the geared turbine, and how he successfully attacked the many problems which arose as the turbine gradually superseded steam engines in power-houses and ships, Sir Alfred made clear with the help of lantern slides, but unfortunately the report of his lecture has no illustrations.

It was once said that the work of Parsons had halved the cost of generating electricity. That is probably well within the mark. The relative importance of turbine plant to-day is shown by the official statistics quoted by Sir Alfred. "British power-stations in 1930", he said, "show that steam

turbines provided more than  $5\frac{1}{2}$  million kilowatts, while all the other types of heat engines accounted for less than a quarter of a million." But neither the generation of power nor the propulsion of ships monopolised the activities of Parsons. He spent much time and money in the attempt to produce artificial diamonds, worked out a scheme for boring a shaft in the earth's crust 12 miles deep, studied the casting of large steel ingots, and in his later years turned to the subjects which had engrossed his father and became a maker of optical glass and a constructor of large telescopes. No one to-day doubts that he was the most illustrious engineer of his time, and a biography of him should prove of the greatest value to students of both science and engineering.

### The Great Barrier and the Formation of Coral Reefs

DR YONGE divided the plan of operations of the Great Barrier Reef Expedition into four sections: (1) the detailed study of the feeding of corals, (2) the plankton and sea-water, (3) an ecological study of corals and associated organisms, and (4) the examination of the bottom flora and fauna, with the determination of the zoning of life at increasing depths (NATURE, 121, 213, 1928). The British Museum (Natural History) has now commenced to publish the results in these four sections. Dr Yonge's own work is mainly included in vol. 1 and has been already sufficiently summarised in NATURE, 127, 309, 1931. It is a very remarkable study of the feeding of corals, from which he concludes that symbiotic algae are "an indispensable factor in the necessarily exceptional powers of growth and repair possessed by the marine communities known as coral reefs." This is as much as concerns the student of the formation of coral reefs.

The methods for the collecting of zooplankton, designed mainly by F. S. Russell, require careful study, but comment is deferred until some quantitative and qualitative results are published. There were 189 hauls of the nets at 68 stations, together with a series of reef-flat plankton collections. For comparative purposes it would be useful if future marine expeditions adopted similar methods. The number of new species of animals obtained in the plankton may be small, the geographical region being the tropics, but the wealth of the collections is indicated in Mr. Barnard's "Amphipoda", more than a thousand specimens (23 species) of *Hyperidea* having been submitted to him for examination.

Vol. 3 contains papers relating to the structure and ecology of reefs. J. A. Steers's geographical introduction is intended for biologists who deal "with definite facts" while geographers "deal with theory." He might have added that biologists on this expedition set out to obtain and test their facts largely by experiment, thus differentiating this from all previous expeditions. Mr. Steers's main work is published in the *Geographical Journal*,

wherein he considers the formation of the Great Barrier Reef. He accepts the view that there was a post-glacial rise of sea-level, the coast platform having been formed largely by low-level Pleistocene abrasion, this following on down-faulting of a peneplain, composed of Pre-Tertiary rocks.

Dr. Stephenson contributes a happy report containing the outlines of the "Development and the Formation of Colonies in *Pocillopora* and *Porites*". He also, assisted by some members of his party, writes a long account of Low Isles and other lagoon reefs, and of one piece of the Barrier Reef. According to Miss Marshall and Dr. Orr's borings, Low Isles reef is a mere veneer of corals and other organisms covering a mud bank (NATURE, 129, 141, 1932). It has a very different foundation from any coral reef visualised by Darwin or any other student of the formation of coral reefs. Dr. Stephenson states that the organisms are extending the surface of the reef outwards, presumably debris being laid down in the waters around in such a way that this outgrowth is assisted. The reef itself was formed as one or more reef patches of a type described as "made of dead boulders and masses of coral with sand between and the surface very irregular and full of complex holes and crevices." The slope to the barrier lagoon is "covered by fixed blocks of dead coral of varying shape" and is illustrated by useful sections. "As the depths of the water increases they tend to become higher, and many of them form very large mounds", the tops often exposed at low water. Their sides are 20 ft. or more deep, and corals grow "on top of them and a little below the top." Nearer the shore they give place to a rugged area "covered by fixed blocks of dead coral." These perpendicular mounds seem to resemble those in the "zone of coral heads" on the lagoon side of Yonge Reef in the barrier series and formerly described in similar places by Surgeon Paradise, who is not referred to. Where I have seen similar structures they were in decay or stationary, and I await further evidence that they have been built

up by corals and are being added to the reef, in particular, I would learn of the destructive as well as of the constructive organisms and processes in and around Low Isles reef

Dr Stephenson should give his reference where he objects to the words "a typical coral reef" as "improper". Surely it is as improper to apply the names he has invented for parts of Low Isles Reef to Yonge Reef of the outer barrier, which appears to have been largely mortared and built by calcareous algæ not present in the former. Yonge Reef has no land and, except boulders, no part projecting above ordinary low tide level, whereas these inner reefs of the lagoon have an elaborate arrangement of cays, ramparts, and rocks above the level at which the building corals can live. Does our author reject the idea that there has been a lowering of sea-level in these regions in very recent times? There is "a general consensus of opinion amongst those who know" as to this (Steers), but in the summary of this report it is not even referred to. Were the superficial structures of Low Isles examined with this recent negative displacement of sea-level in view? If not, they require re-examination. In particular, the rocks shown in Plate V, Figs 3 and 4, might just as well be parts of a formerly continuous reef which is slowly washing away as boulders, if so, many of their building organisms should be in the position in which they grew.

Yonge Reef "was chosen for careful examination" so that a full account will doubtless follow. It is of infinitely greater importance to the student of coral reef questions than all these lagoon reefs. A reef against the open ocean in such a position has usually an outer narrow ridge a few yards behind the breakers broken by trenches, a reef flat at about low tide level, often in places a little lower, a boulder zone, and a lagoon flat. Yonge Reef is described as having the same outer ridge, inside which is a depression (outer moat) up to 5 ft deep and 100 yards broad. Then comes the "reef crest" a pavement of solid coral rock, swept clear of debris 160 yards in breadth", more or less exposed at low water, and this is succeeded by an ill-defined depression (inner moat) 50 yards broad, up to 18 in deep, rising into the boulder zone. The crest and inner moat seem to us to be comparable with the inner half of what is termed the reef-flat and to carry the same organisms, but the outer depression, up to 5 ft deep, is a most unusual feature that merits full description. We presume that it was found at Ribbon, Ruby, and Escape Reefs, justifying the statement that Yonge Reef is typical. It would help us to understand this reef had there been any mention of the genera of building algæ in the list of its fauna and flora and referred to as a "heavy incrustation of nullipores". In any event, Yonge Reef should never have been blended in this report with a series of lagoon reefs many miles away from the open ocean, for it will throw those who have not made personal examinations of coral reefs into inextricable confusion.

The systematic work of the bottom fauna is

published in vol 4, which at present contains nine reports. It commences with that of the Annelida by Mr. C C A. Monro, but was it worth his time to examine a collection of 46 species of Chaetopoda, of which more than half are represented only by single specimens? Clearly this class of animal, so important on shallow reefs, was never collected, and subsequent reports lead us to believe that only the obvious forms of life in such positions were collected. Enteropneusts suggest a similar story, only 2 species with 12 species of larvæ being described by E. Trewavas. Low island reefs should be almost ideal for the adults, and yet there are recorded only 21 specimens of *Ptychodera flava* and 8 "fragments" of *Balanoglossus carnosus*, which is described as "common on most sandy places". If only Mr. Monro, who has the specialist's knowledge, could be sent out to collect such groups of animals, on a tropical coral reef coast, what information we would have! He would settle his species on the spot, and in a second year his report would be completed! It would be of more value to science than twenty years in a museum working on collections such as this. Neither he nor Mr. Lyman Clark, who had more than five hundred specimens of Echinoderma other than Asteroidea, 117 species in 66 genera, thinks it worth while to consider geographical distribution. There are very few field notes, and the reader will inevitably conclude that the expedition did little collecting work. This is unfortunate, as a knowledge of the whole fauna and flora of the region is essential to an ecological study of any part.

Another report in this series is Prof. S. J. Hickson's revision of the genera and species of the Xenudæ. It is of high scientific importance and of great educational value to future taxonomic workers on sedentary animals. The desirability of field observations is clear, Dr. Manton's note, "not the same species as on Escape Reef", leading to the discovery of a new species. It is also pleasing to see that the British Museum has a good taxonomist to deal with Tunicates in the person of A. B. Hastings, who appears temporarily to have deserted Polyzoa. G. P. Whitley, ichthyologist to the Australian Museum, collected most of the three hundred and fifty specimens of fish, which he assigned to a hundred species, and his field notes are fuller than usual. He remarks that the region is not sufficiently analysed for a synthesis of the geographical distribution of fish. A. A. Livingstone, of the same museum, has 33 species in 20 genera of Asteroidea, but by a slip New Ireland is placed in the Maldives. We would also refer to an excellent study of *Trochus* by the Australian naturalist, F. W. Moorhouse (vol 3). It feeds on algæ, which it rasps off the rocks, and its optimal area appears to be on the relatively bare weather sides of reefs between tide marks, where the water is well aerated and every bare surface is covered by such algæ. Tables of size frequencies and of monthly rates of growth are given. Breeding takes place after two years, the *Trochus* being then about 5.5 cm in diameter, the full size being about 9 cm.

J. STANLEY GARDINER

## Obituary

PROF. WILHELM OSTWALD

**W**ILHELM (FRIEDRICH) OSTWALD, whose death took place on April 4, was the most notable and widely known figure in the history of physical chemistry during the quarter of a century which preceded his retirement from active academic work in 1905. Of this branch of science, in fact, he may quite properly be called the founder.

Born at Riga on Sept. 2, 1853, and educated at the recently established *Realgymnasium* in his native town, Ostwald entered the University of Dorpat in January 1872. In 1877 he became *magister* and *privatdozent*, and in 1878 he obtained the degree of doctor. Three years later, he accepted a call to the chair of chemistry in the Polytechnic at Riga, where he remained until 1887. It was at Riga that Ostwald's amazing powers as an organiser, thinker, investigator, and teacher had, for the first time, free opportunity to unfold themselves and to grow in strength. There he organised his teaching on a physico-chemical basis, and his aim was to train his students to be scientific thinkers. It was to Ostwald's laboratory at Riga that Arrhenius came in 1885, seeking help and sympathetic understanding of his work.

In 1887, Ostwald was invited to fill the chair of physical chemistry at Leipzig in succession to G. Wiedemann, and it was in Leipzig, first in the buildings of the Agricultural Institute and then, from 1897 onwards, in the new Physical Chemistry Institute in the Linnéstrasse, that Ostwald's greatest work as a teacher, writer, investigator, and inspirer of research was carried out, and it was during his Leipzig period that his intellectual and creative powers attained their zenith.

Ostwald retired from his chair at Leipzig in 1905 and, in the same year, he was nominated by the German Emperor as first exchange professor to America. In 1909 he was awarded the Nobel prize in chemistry.

In a short notice it is not possible to give more than an indication of some of Ostwald's scientific and literary achievements. In his work as an investigator, Ostwald, by his own hands or with the help of a large number of students who flocked from all parts of the world to his laboratory, laid the foundations of large sections of physical chemistry. Problems of chemical affinity, strength of acids as determined by density measurements, distribution between bases, effect on hydrolysis of methyl acetate, etc., were the subjects which first attracted his attention, and he discovered, independently of Arrhenius, that the conductivity and chemical activity of acids run parallel. Then came the development of electrochemical studies—electrical conductivity and electromotive force measurements as methods of studying chemical activity, solubilities, etc.—and out of these studies came the dilution law and Ostwald's devotion to energetics. Lastly, in the laboratories at Leipzig, the foundations of the study of catalysis were well and truly laid. By

no other leader in chemical science has such a wide range and variety of scientific interests been manifested.

Great, however, as were Ostwald's experimental contributions to physical chemistry, his work as teacher and as champion of what might then be called the new learning (van't Hoff's theory of solutions, Arrhenius's theory of electrolytic dissociation, etc.) was perhaps of still greater value for the advance of science. An enthusiastic lover of his subject, Ostwald was possessed by the spirit of the missionary and the teacher. To the joy of creating and acquiring knowledge was added the equally great joy of passing on his knowledge and mental outlook to others. Ostwald was a master both of the spoken and of the written word, and once his orderly and clear-thinking brain had arranged his ideas, he could give rapid and unhesitating expression to them in clear and smooth-flowing language. His extraordinary memory, moreover, never failed to supply him with apt illustrations with which to adorn an argument.

In the early days at Riga, Ostwald collected together all that was known in the department of physical chemistry, and so gave to all serious students his "*Lehrbuch der allgemeinen Chemie*" (1885–1887), and in order to promote the study of physical chemistry and to provide an organ for its expression, he founded, in collaboration with van't Hoff, the *Zeitschrift für physikalische Chemie*. From that time, book after book—his "*Grundriss*", his "*Elektrochemie*", his "*Hand- und Hilfsbuch*", his "*Grundlinien der anorganischen Chemie*", his "*Schule der Chemie*", etc.—poured from his pen. To the all-compelling power of Ostwald's personality, to his burning enthusiasm, and to the freshness, breadth, and inspiration of his personal teaching and of his writings, physical chemistry owes a very special debt.

By the end of last century, Ostwald's interest in a specialised branch of science had developed, quite naturally as he felt, into an interest in generalised knowledge or philosophy, and, in 1902, he published his "*Vorlesungen über Naturphilosophie*", which attracted much attention at the time and received the warm appreciation of William James. As was natural with Ostwald, there followed on the publication of his "*Vorlesungen*" the founding of the periodical, *Annalen der Naturphilosophie*. So Ostwald, the apostle of physical chemistry, became the apostle of the doctrine of energy as the fundamental basis of reality.

Although Ostwald had never been much interested in industrial chemistry, he felt it to be his patriotic duty to make his country independent of others for the supply of the nitric acid necessary for the manufacture of explosives, and he turned his attention, therefore, to the production of nitric acid by the catalytic oxidation of ammonia. The process which he developed was the main source of Germany's supply of nitric acid during the War.

Ostwald was a man of large mind and large heart,

he spoke his mind freely and always put forward his views with enthusiasm and conviction, but he neither scorned nor regarded lightly the honestly held views of others. His honesty of purpose, his enthusiasms, his freshness of mind, and the variety of his interests gave to all intercourse with him a charm which impressed all those who had the privilege to partake of it. To his purely scientific interests he added an intense interest in music and painting, and the exercise of these two arts was the means whereby a tired and sometimes overwrought brain became rested and refreshed. To his interest in painting is no doubt due the interest which, during the later years of his life, he took in the theory of colour, his views regarding which he has expounded in his book, "Physikalische Farbenlehre", and in other books and memoirs.

ALEX FINDLAY

#### DR H T FERRAR

THE death of Hartley Travers Ferrar at the comparatively early age of about fifty-two years was announced in London on April 19. Leaving Oundle in 1898, he entered Sidney Sussex College, Cambridge, and took a second class in the Natural Science Tripos in 1901. Besides being captain of his College boat club he rowed in the University trials, and it was when stepping out of an eight at Henley that he was offered a place as geologist to Capt. Scott's First Expedition to the Antarctic. The chief scenes of his labours on the expedition were in South Victoria Land, where the great Ferrar Glacier was named after him.

On his return to Cambridge in 1904, Ferrar was elected a fellow of the Geological Society and spent several months in writing up his observations. Living beneath the same roof with him at this time, and discussing almost daily his many problems, I learned to appreciate—possibly as few could who had not accompanied Scott—those sterling qualities that had enabled him to accomplish so much, and won him so many lifelong friends.

In the autumn of 1905, Ferrar joined the Egyptian Survey and before Christmas had made a long camel trip into the Eastern Desert beyond Edfu. By April 1906 he was in the Western Desert (Siwa Oasis) beginning to interest himself in water-supply. In late 1907 he commenced field-work in Upper Egypt on the movements of subsoil waters, with particular reference to their effects upon cotton and other crops, and this study was extended to Lower Egypt in subsequent years. Results were published as a Survey Department paper in 1911. During 1910–11 he made a series of experiments, in association with the Department of Agriculture, on the effects of movements of the water-table on the cultivation of cotton in the Delta, in the course of which he set out many lines of tube wells and recorded thousands of observations. The experiments proved that there was (up to a limit) a steady increase in the crop yield with increase in the thickness of soil above the water-table. The findings were issued as a Survey Department paper in 1912. During this period also he visited the oil-fields.

Somewhere about 1912, Ferrar retired from the

Egyptian Survey and proceeded to New Zealand, his wife's home country. The outbreak of war saw him in Egypt again, with the New Zealand Forces, and later he became an efficient map-officer attached to the Australian Flying Contingent in Palestine.

In 1919, Ferrar was appointed geologist to the New Zealand Survey (Department of Scientific and Industrial Research) in which he had risen to the position of assistant director at the time of his death. Amongst other publications, an important *Bulletin* (No. 27, New Series, 1925), written mostly by himself, "On the Geology of the Whangarei-Bay of Islands Subdivision, Kaipara Division", describes the results of the survey of 1905 square miles in North Auckland and deals largely with mineral deposits. In his latest outstanding work (*Bull.* No. 33, New Series, 1929), "On the Soils of Irrigation Areas in Otago Central", his Egyptian experiences were invaluable, as shown by his discussion of the irrigation problems. His soils are classified into series, classes and types, and such subjects as climate, drainage, soil-profile, youthful and mature soils are considered.

It was largely on the strength of this last publication that, in February last, Ferrar was awarded the degree of D.Sc. (Diploma) by the University of New Zealand. Besides his official publications, some thirty papers on different subjects were contributed to scientific journals in Great Britain, Egypt, and New Zealand.

In May 1931 old memories were revived when the *Discovery* called in at Wellington on its way to southern latitudes.

BERNARD SMITH

WE regret to announce the following deaths

Dr. Albert P. Brigham, professor emeritus of geology at Colgate University, president in 1918–19 of the American National Council of Geography Teachers, on April 1, aged seventy-six years.

Mr. Donald R. Dickey, a research associate of the California Institute of Technology, who was an authority on the birds and mammals of North and Central America, on April 16, aged forty-five years.

Dr. B. K. Emerson, for forty-seven years professor of geology at Amherst College, and president in 1899 of the Geological Society of America, on April 7, aged eighty-eight years.

Prof. C. S. Hastings, professor and emeritus professor of physics at Yale University since 1884 and a member of the U.S. National Academy of Sciences, a well-known designer of astronomical telescope objectives, aged eighty-three years.

Sir Thomas Legge, C.B.E., for nearly thirty years senior medical officer of factories at the Home Office and afterwards medical adviser to the social insurance section of the Trades Union Congress, who took a leading part in the promotion of industrial health in Great Britain, on May 7, aged seventy years.

The Hon. Dr. William Pember Reeves, formerly Agent-General and afterwards High Commissioner for New Zealand, who was director in 1908–19 of the London School of Economics, on May 15, aged seventy-five years.

## News and Views

### Christopher Borrus

It is a tradition of the Society of Jesus that St Ignatius, its founder, was wont to watch the heavens in order that his heart might be inflamed with the love of God from the consideration of the wonders of His work, and from almost its earliest days the Society has included men who have devoted themselves to astronomy and other sciences. Clavius, Scheiner, Grimaldi, Hell, Mayer, Boscovich, Secchi, and Perry are but a few of the men of science who have belonged to the Society. One of the first, however, was Christopher Borrus, who was born in Milan in 1583, joined the Society in 1601, and died on May 24, 1632, three hundred years ago. Like Fathers Trigault, Rhô, and Schall, he was sent as a missionary to the Far East, and wrote a valuable account of Cochinchina. He made observations on the variation of the compass, and, according to Kircher, drew up the first charts of the Atlantic and Indian Oceans, showing the spots where the magnetic needle makes the same angles with the meridian. He was thus a forerunner of Halley. His explanation of the chart is contained in a manuscript which belongs to the Royal Academy of Lisbon. He also made suggestions as to a new method for determining longitude at sea. After some years spent in the East, he returned to Europe, and taught mathematics at Coimbra. His death took place at Rome shortly after he had entered the order of Cistercians.

### The Varley Brothers

In an interesting address on the brothers Varley, who did much valuable pioneering work in telegraphy and electrical engineering, Col. Lee, of the Post Office, in a lecture on May 5 to the Institution of Electrical Engineers, pointed out that the whole progress of telegraphy during the constructive period up to the laying of the Atlantic cable was largely the history of Cromwell and Samuel Alfred Varley. This year is the hundredth anniversary of the birth of S. A. Varley. Cornelius Varley, the father of the two brothers, was a well-known scientific worker, and delivered the fourth Friday evening discourse at the Royal Institution. He was a descendant of Oliver Cromwell. The first attempts to lay an Atlantic cable having failed, Cromwell Varley served on a committee appointed by the cable company which issued a most valuable report. Later on, Cromwell Varley and Sir William Thomson (Lord Kelvin) entered into partnership as consulting engineers, being joined later by Fleming Jenkin. Cromwell Varley wrote many scientific papers, one of them published by the Royal Society describing experiments on luminous phenomena which came very near to discovering the electron. Samuel Alfred Varley did much valuable work in telegraphy. During the Crimean War, he laid the first field telegraph in 1854. His greatest invention was the self-exciting dynamo, on which he had been experimenting since he was seventeen years of age. On technical

grounds the priority of this invention is generally attributed to others. At the International Inventions Exhibition in 1885, he was awarded a gold medal for inventing a self-exciting dynamo. He championed the cause of the electrical industry against the Brush patent for the compound wound dynamo. Varley's precedence in the invention was upheld after an appeal to the House of Lords and the Brush patent was declared invalid. Both the brothers Varley and the late Earl of Crawford played a leading part in founding the Institution of Electrical Engineers. Among the seventy-one founder members were four of the Varley family.

### Life and Work of Dr. James Murie

DR. JAMES MURIE, well known for his work on the Thames fisheries, was born on March 30, 1832, and he died in 1925. To commemorate the centenary, Mr. A. Lawrence Wells gives an interesting account of his life and work in the *Southend Standard* of March 31 last. Murie is chiefly remembered for his later work at Leigh, where he lived and did valuable service in connexion with the local fisheries, but his early career was full of adventure. Educated for the medical profession at the University of Glasgow and specialising in zoology, he first worked at the Royal Infirmary, Glasgow, proceeding to the Royal College of Surgeons in London as assistant in the Museum, where, under Prof. J. E. Quekett, he worked at comparative anatomy, especially aquatic mammals. After two years at the Museum, he travelled through Europe and made several voyages as ship's surgeon, finally joining the expedition to the White Nile under John Petherick, who was meeting Capt. Speke and Grant for exploration of the western tributaries of the White Nile. The expedition, disastrous as it proved to be as regards Petherick's party, was yet productive of much valuable zoological material, and the fish collection was declared by Dr. Gunther to be the finest ever received from that part of Africa.

On his return to England, Murie again worked at the Royal College of Surgeons, arranging and cataloguing the collection of slides left by Prof. Quekett, then becoming prosecutor for the Zoological Society, and later sub-editor of the Linnean Society's publications. It was whilst working for the Linnean Society that he rented a cottage at Leigh and so began his interest in the Thames fisheries. These various employments no doubt helped in his later work, which he made peculiarly his own. Besides his practical help and constant sea-going with the fishermen, he reported on the fisheries for the Kent and Essex Sea Fisheries Committee, which required much original research. The first part of this valuable report on the Fisheries of the Thames Estuary has been published, the second part, as has been already noticed in *NATURE* (May 14, 1927, March 5, 1932), is partly in proof and partly in manuscript, and the whole is now in the Southend Library.

### New Foreign Members of the Linnean Society

At the meeting of the Linnean Society of London on May 12, the following were elected foreign members.—Prof Klas Robert Fries, director of the Botanic Garden, Stockholm, who has made very important contributions to our knowledge of the flora of South America, chiefly of the Argentine, Bolivia, and Brazil. His work on the tropical American *Anonaceæ*, *Amarantaceæ*, and *Colonnifereæ* (Malvales) and his monographs of *Wissadula* and *Petunia* are especially noteworthy. He has also done valuable work on the flora of Rhodesia, the Congo, etc., and has made contributions to mycology. Prof Eduard Fischer, professor of botany at the University and director of the Botanical Institute, Bern, distinguished for his works on a wide range of mycological subjects since 1883. He has devoted especial attention to the Gasteromycetes, on which he contributed the section in Engler and Prantl's "Pflanzenfamilien". He has produced monographic studies of the Rusts of Switzerland, and carried out extensive studies of the biology of heteroecious rusts. He collaborated with E. Gaumann in the most complete work on the biology of parasitic fungi that has yet been published. Prof Ludwig Jost, director of the Botanical Institute and Gardens, University of Heidelberg, known for his work as a teacher of plant physiology and his influence on the development of his subject. Prof Émile Topsent, professor of zoology and comparative anatomy, University of Strasbourg, the leading authority in the world on sponges. His first paper was published in 1887, since when he has published a number of papers and several important books, including reports for the Prince of Monaco. His large quarto volume—"Campagnes . . .", Monaco, 1928—is the most up-to-date monograph on sponges.

### U.S. National Academy of Sciences

It is announced by Science Service that the following have been elected foreign associates of the U.S. National Academy of Sciences: Marchese Guglielmo Marconi, Prof Karl von Goebel, Munich, Prof H. Wieland, Munich, Prof Fritz Haber, Berlin. Fifteen new members were elected: Dr R. T. Birge, University of California, physics, Dr E. G. Borng, Harvard University, psychology, Dr S. R. Detwiler, Columbia University, anatomy, Dr W. A. Jacobs, Rockefeller Institute for Medical Research, New York City, chemotherapy, Dr D. W. Johnson, Columbia University, geology, Dr L. O. Kunkel, Boyce Thompson Institute, Yonkers, N.Y., plant physiology; Dr K. Landsteiner, Rockefeller Institute for Medical Research, New York City, immunology and pathology, Dr W. C. Mendenhall, U.S. Geological Survey, geology, Dr Marston Morse, Harvard University, mathematics, Dr F. K. Richtmyer, Cornell University, physics, Dr J. C. Slater, Massachusetts Institute of Technology, Cambridge, Mass., physics, J. R. Swanton, Bureau of American Ethnology, Washington, D.C., anthropology, Dr R. J. Trumpler, Lick Observatory, Mt. Hamilton, Calif., astronomy, Dr E. W. Washburn, U.S. Bureau of Standards, and editor-in-chief of International Critical Tables, chemistry,

Dr J. B. Whitehead, the Johns Hopkins University, mathematics and philosophy.

### Jericho

RECENT correspondence in the daily Press on the Exodus and its relation to the fall of Jericho was no doubt to some extent responsible for the interest taken in the account of the third season's excavations on the site of that city given by Prof John Garstang before the Royal Asiatic Society on May 12. Although two seasons' work had produced no certain evidence of dating, Prof Garstang on opening his third season had arrived at an opinion, based on the evidence of stratification as well as the absence of any sign of Mycenaean contact, that the conflagration which destroyed the city, and of which there is abundant evidence, had taken place during the late Bronze Age, probably somewhere about 1400 B.C. With the view of obtaining datable objects which might or might not confirm this view, the Bronze Age cemetery some four hundred yards west of the city mound was attacked and twenty-five tombs were opened and cleared. Objects numbering eighteen hundred, the great majority pottery, were obtained covering the history of the site throughout the Bronze Age. Most significant of all, however, were ninety-four royal Egyptian scarabs, which have been examined by Prof Newberry and pronounced by him to range from the Hyksos period to the reign of Amnhotep III. Egyptian influence first appears about 1500 B.C., but nothing of the Tel el-Amarna period and the age of Akhenaton has been found. It is, therefore, concluded that the city was destroyed at some date between 1411 B.C. and 1375 B.C. Evidence of re-occupation appears in the Iron Age, but the walls were not rebuilt until about 900 B.C.

### Excavation in Southern Palestine

SIR FLINDERS PETRIE briefly summarises the results obtained by the British School of Archaeology in Egypt at Tel Ajjul up to the close of the past season's excavations, in the *Times* of May 13. The results fully bear out his opinion that the early history of Palestine has been more fully explained on this site than on any other in the country. The evidence it has afforded extends from the rock-cut tombs of the Copper Age, c. 3400 B.C., in which copper daggers and pottery were found, to the age of Thothmes III, after whose day the site was abandoned until it was occupied again by Arab squatters in the Middle Ages. No less than five palaces were erected on the limestone hill, of which the limits were artificially extended to take the greater area covered by the later buildings. The first palace was erected by the people who introduced bronze from North Syria and whose invasion founded the Eighth Dynasty of Egypt. The second palace, Sir Flinders Petrie considers, was probably erected by the founders of the Twelfth Egyptian dynasty, while the third and fourth were the work of the Hyksos. The later Hyksos palace has afforded evidence of a foundation sacrifice in which the body of a horse was flung into a pit. Its shoulders and the bodies of two other horses afforded the

material for a sacrificial meal. One of the most noteworthy finds was a gold torque, in form similar to the torque found at Troy and presumably of Irish origin. Lectures on the work of the season are being given at University College, London, on May 19 at 2.30 P.M. and May 21 at 3 P.M., entrance free, without ticket; and the usual exhibition will be open at the College on July 11-Aug. 6.

#### Animals and Electric Shocks

It is well known to electricians that animals are much more sensitive to electric shock than human beings. Quite low voltages, of the order of 20 volts, are dangerous to cattle and horses. About twenty years ago, when rural electrification began to increase on the Continent, fatalities to these animals began to occur, and it was found necessary to devise methods for mitigating the danger. As the electrification of farms has now been begun in Great Britain, the paper by T. C. Gilbert in the *Electrician* for April 29, in which he discusses some of the effective safety devices used abroad, should prove useful. Wiring systems where the 'live' wires are surrounded by metal which is connected to 'earth' are perhaps the safest, at least in towns, where the mains of the water supply system, into which any leakage currents usually flow, form an excellent earth. In rural districts, earths are made by burying metal plates or pipes. In this case the resistance of the earth may be of the order of 50 ohms, and so even if a leakage current be less than an ampere, the difference of potential of the ground near where the pipe is inserted and four feet away may cause a dangerous shock to a large animal standing with a foreleg near the pipe and a hindleg four feet from it. Mr. Gilbert records a very exceptional case where no less than six cows in one farm were killed from this cause. So far as we know, no fatalities to human beings have ever occurred in this way. We have heard of cases where mild shocks have been felt in the street, when a pedestrian steps from one part of the pavement to the other, due to a fault in an underground main. The effective methods used abroad show that the risks to cattle can be made almost negligible.

#### Spore Dissemination through the Upper Atmosphere

DURING the War, aeroplanes came to be used to an increasing extent for the direct investigation of meteorological conditions in the upper atmosphere. We learn from an article that forms one of the "Why the Weather" series, by C. F. Talman, issued by Science Service, Washington, D.C., that the aeroplane is being used in analogous biological investigations by the U.S. Bureau of Plant Industry to determine, among other matters, the height to which the spores of the dreaded black stem rust occur in the American spring wheat area. The spores are collected on glass microscope slides covered with a very thin coating of vaseline. It has been found that they extend up to a height of about 10,000 ft above the earth. From the results of other investigators on the rate of fall in still air of the spores of white-pine blister rust, a spore only slightly smaller than the black stem rust spore,

it may be concluded that the black rust spores would occupy about two days in falling from 10,000 ft to the ground, in the absence of any net upward or downward component of the wind. Since it is no rare event for the wind above the first few hundred feet to travel a thousand miles or more in a day, it is evident that regions lying far to leeward of infected areas may receive spores from these great altitudes.

#### Cave Exploration in Western China

THE United States National Museum has received a large collection of objects which have been obtained from the caves of Szechwan, Western China, by Mr. David C. Graham, of the Smithsonian Institution, Washington, D.C. This explorer has found that a large number of the innumerable caves of Szechwan and the Tibetan border were used as tombs by the Chinese at about the beginning of the Christian era, but no evidence is forthcoming to support the view that they were once inhabited by aborigines who preceded the coming of the Chinese. The caves are generally found in steep places, both singly and in groups. They are difficult of access, and vary in depth from a few feet to 130 feet, being about six feet wide and six feet high. Some show signs of chisel marks. Nearly all the caves have coffin niches, the coffins being of earthenware. Some coffins, however, are merely cavities chiselled in the stone and fitted with stone lids. Among the funerary offerings, the large number of figurines of human form is noteworthy. Some of these in costume and general appearance present a remarkable similarity to the people of to-day.

#### Norman Lockyer Observatory

SIR FRANK DYSON, Astronomer Royal, will open the new Mond photographic equatorial and dome at the Norman Lockyer Observatory, Salcombe Regis, Sidmouth, on May 28. The Norman Lockyer Observatory is the only astronomical observatory in Great Britain founded and maintained by a private corporation under the Companies (Consolidation) Act of 1908. Since it was started, nearly twenty years ago, it has been equipped and maintained entirely by private donations. The equipment includes two twin telescopes, one with a 10 in. object glass and a 12 in. prismatic camera, and the other with a 10 in. object glass and a 9 in. prismatic camera for photographing the spectra of stars and other celestial bodies. A very large collection of such photographs, numbering 6500, has already been taken at the Observatory, affording valuable records of the nature and movements of objects in the stellar universe. Dr. Robert Mond, who has been a generous supporter of the Observatory since it was founded, has now presented a unique photographic equatorial, with a separate building and dome to house it. The instrument consists of a battery of four cameras with clock mechanism, so that it will be possible to follow automatically movements of the heavens over a wide field of the sky.

#### Expeditions of the Soviet Academy of Science

THIS year the Soviet Academy of Science is sending out ninety-nine scientific expeditions to explore

remote regions of the Union, including the Kola peninsula, the Ural-Kuznetsk Basin, Transbaikalia, the Turukhan region, East Sayan, the Irkutsk region, the Minusinsk region, Buriat Mongolia, and Tanu-Tuva, also the salt and soda lakes of the Kulundin steppe in western Siberia. Aeroplane photography will be used to establish the extent of the Siberian forests. The expedition to Kazakstan is to explore the natural resources of the Karagandin, Koundar, and the Dzeskazgan regions of the Altai and Ridder, and to investigate the possibility of reconstructing the agriculture of north Kazakstan. Seventy-five detachments are starting for Central Asia to explore the natural resources of Tadzhikistan, Turkmenia, Uzbekistan, and Pamir. It has been decided to start to explore this year the natural resources of Khirghizia, which possesses much potential hydraulic power and big deposits of ferrous and non-ferrous metals, and has suitable lands for cattle-breeding. The expedition to the Crimea is to concentrate on the exploration of the salt lakes. The expedition to Transcaucasia will examine the possibilities of utilising hydraulic power in the region, that to the northern Caucasus is to explore the deposits of rare elements such as cadmium and the mineral resources of the main ridge of mountains of the region. In Balkaria an investigation will be made of the soil of the mountain grass-lands. To cover the cost of the expeditions, the Government has allocated six million roubles, and additional sums will be supplied if necessary. These expeditions are to follow up previous exploration work carried out by the Academy of Science in the Yakutsk, Buriat-Mongolsk and Transbaikalian regions, which resulted in the discovery of medicinal and other plants suitable for export, and of new areas for rice-growing.

#### Buildings for Science Departments

At the instigation of the British Science Guild, the Royal Institute of British Architects has undertaken an inquiry into the design of science departments with the view of affording guidance in the matter of accommodation, fittings, finishings, and supply services. An elaborate questionnaire has been drawn up in convenient column form asking for particulars of the sizes of rooms for definite numbers of students, their aspect, wall and floor surfaces, and various laboratory fittings considered desirable. Replies are to be sent to Mr. Alan E. Munby, Science Standing Committee, Royal Institute of British Architects, 9 Conduit Street, London, W.1. Science departments, of course, fall into different categories, and the present inquiry is confined to provisions for higher teaching and research and has been sent to the heads of departments of the universities of the British Empire and certain research institutions. Should an analysis of the returns justify it, the Council of the Royal Institute of British Architects may issue a short report which would put architects and engineers into closer touch with the specific needs of science departments. There can be little doubt that, given adequate response, the questionnaire will give designers of new science departments a valuable body of data on which to base their work.

No 3264, Vol. 129]

#### Mice Plague in Australia

PROF W A OSBORNE, University of Melbourne, sends us the following cutting from the Melbourne *Argus* of March 30, dealing with the present mouse plague in Victoria, Australia. "After all wheat had been trucked from the Lah railway station, near War-racknabeal, a raid was made upon the mice. The site was fenced, and two 40-gallon oil drums were sunk in the ground. The dunnage was then cleared and the mice driven into the drums. On the first night the catch, placed on the weighbridge, weighed one ton, and on two successive nights 8 cwt and 10 cwt were caught, the weight for the three nights being nearly two tons." Prof. Osborne informs us that the greatest visitation of these pests occurred in 1917, when enormous stacks of bagged wheat remained in various railway sidings. The plague was first noticed in February and March of 1917, it was at its acme between April and August of the same year. At Lascelles, three tons, approximately 200,000 mice, were caught in one night. Until the end of June 1917, the recorded total caught was 544 tons, at least 32,000,000 mice.

#### International Congress of Scientific Management

THE Fifth International Congress of Scientific Management will be held at the Kolomaal Instituut, Amsterdam, on July 18-23. The subjects to be discussed include costing, markets, technical and mental education of foremen for rationalisation, systems of promotion, rationalisation as a part of education, costs of retail distribution, agricultural labour, and rationalisation in various types of industry. Papers from many countries have been contributed through the national associations or committees and are being published in two volumes in advance of the meeting; summaries only will be read at the sessions of the Congress. Excursions in Amsterdam, to Eindhoven, the Zuider Zee, and to Rotterdam are being arranged, and continental railways are giving special facilities for those attending the Congress. The general secretary for the Congress is Mr V. W. van Gogh, Herengracht 209, Amsterdam—C. English visitors can obtain particulars from the honorary secretary, Institute of Industrial Administration, 44 King William Street, London, E C 4.

#### South-Eastern Union of Scientific Societies

THE thirty-seventh annual Congress of the South-Eastern Union of Scientific Societies will be held in London, at the Civil Service Commission, Burlington Gardens, W.1, on June 1-4, under the presidency of Dr R. E. Mortimer Wheeler. The presidential address, on "Field Archaeology in Great Britain", will be delivered in the evening of the first day of the Congress. The sections, their presidents, and the subjects of the presidential addresses are as follows: archaeology, Dr W. E. St. L. Finny, "Medieval Games and Games"; botany, Mr J. Ramsbottom, "Fungi as Scavengers"; geology, Prof H. L. Hawkins, "The Structure of the South-East of England"; zoology, Mr Hugh Main, "The Camera as a Naturalist's Recorder"; regional survey, Mr G. L. Pepler,

"Town and Country Planning" Evening lectures will be delivered by Sir Arthur Thomson, on "The Drama of Animal Life", and by Capt Guy Dollman, on "Great Game Animals of Africa". There will be an exhibition of regional survey material under the supervision of Miss E W Spear, and a number of excursions of specialised interest, as well as others of more general appeal, have been arranged. The honorary general secretary of the Congress is Mr E A Martin, 14 High View Close, Norwood, London, S E 19.

#### World Power Conference

A SECTIONAL meeting of the World Power Conference will be held in Scandinavia on June 26-July 10, 1933. All countries represented on the organisation are invited to attend and take part in the discussions, which will be mainly in connexion with large factories taking power in bulk and traction. The iron and steel industries, railways, and marine transport will be specially considered. Many attractive excursions have been arranged, and receptions will be held in Copenhagen, Stockholm, and Oslo. A contingent will also make a visit to Finland by aeroplane. In a bulletin issued from the office of the World Power Conference, 63 Lincoln's Inn Fields, W C 2, D N Dunlop, the president of the International Executive Council of the Conference, contributes an interesting article on its functions. He says he has little belief in the ability of politicians and bankers by themselves to solve the problems that at the present moment menace our civilisation. By 1933 the immediate problems will probably have changed, but no real beginning to economic reconstruction can be made until the nations of the world embark on a rational policy for the organisation of production and distribution. The world needs practical vision. Without this, what we have already brought about in the way of technical and scientific co-operation may be swept away. The scientific and technical industries of the world are the result of the creative activity of men of all nations, it is on us that there now falls the task of seeing that this activity is fully utilised.

#### Announcements

THE Lister Medal for 1933 for distinguished contributions to surgical science has been awarded by the Royal College of Surgeons to Sir Charles Ballance, who will deliver the Lister Memorial Lecture at the College on some date in 1933.

It is reported by the Madrid correspondent of the *Times* that a great part of the University of Valencia was destroyed by fire on May 12. Much damage was done, the astronomical observatory and the faculties of natural history, physics, and chemistry, with their collections and laboratories, being destroyed. Most of the contents of the library have apparently been saved.

THE need of qualified people, able to interpret scientific thought and activity so as to make it available

to a larger public, has led the School of Journalism of Paris (part of the Institut des Hautes Études) to arrange a course of lectures on scientific journalism. It is intended both for students and for practising journalists. The lecturer, M René Sudre, scientific editor of *Le Journal*, is well qualified for his difficult task. The journalistic profession will certainly benefit by its realisation that scientific reporting is a branch of journalism that requires special training.

A CATALOGUE (No 19) of some 321 second-hand books on gardening and botany has reached us from Mr J H Knowles, 23A Beulah Hill, S E 19.

THE latest catalogue of Messrs Dulau and Co, Ltd, 32 Old Bond Street, W 1 (No 199), relates mainly to second-hand botanical books and periodicals, herbals, floras, and general natural history. There is also a section of interesting miscellaneous works. Copies may be had free upon application to the publishers.

AN interesting catalogue (New Series, No 27) of upwards of 800 second-hand books on gardening (including herbals), agriculture, and husbandry (1481-1800) has just been issued by Messrs Wheldon and Wesley, Ltd, 2 Arthur Street, W C 2. Many rare volumes are offered for sale, and useful bibliographical notes are appended to some of the titles.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A teacher of chemistry for day and evening classes at the Wandsworth Technical Institute—The Secretary, Technical Institute, Wandsworth (May 25). A full-time teacher of engineering subjects at the Acton Technical College—The Principal, Technical College, Acton, W (May 27). A Graham scholar in pathology in the University of London—The Academic Registrar, University of London, South Kensington, S W 7 (May 29). A lecturer in mechanical and aeronautical engineering at the Northampton Polytechnic Institute—The Principal, Northampton Polytechnic Institute, St. John Street, E C 1 (May 31). A lecturer in production engineering in the Department of Mechanical Engineering of the Birmingham Central Technical College, and a lecturer in building and allied subjects in the Department of Building and Structural Engineering—The Principal, Central Technical College, Suffolk Street, Birmingham (June 3). A joint professor of mining in the University of Glasgow and the Royal Technical College, Glasgow—The Secretary, University Court, The University, Glasgow, W 2, or The Secretary, Royal Technical College, Glasgow (June 11). A secretary of the Chartered Surveyors' Institution—The Hon. Secretary, Chartered Surveyors' Institution, 45 Parliament Street, S W 1 (June 20). A Tennent professor of ophthalmology in the University of Glasgow—The Secretary, University Court, University, Glasgow. A woman temporary lecturer in mathematics at the Lincoln Training College—The Principal, Training College, Lincoln. A director of the West of Scotland Neuro-Psychiatric Research Institute, Glasgow—The Secretary, Hawkhead Asylum, Crookston, Glasgow.

#### Suggested Wireless Observations during the Solar Eclipse of August 31, 1932

At a recent Geophysical Discussion at the Royal Astronomical Society (an account of which has been published in the March issue of the *Observatory*) the possibility of deriving information concerning the nature of the solar radiation responsible for upper-atmospheric ionisation by means of wireless observations made during a solar eclipse was discussed by us. It is known that the agents principally responsible for the ionisation in both of the atmospheric ionised layers travel rectilinearly, so that both ultra-violet light and swiftly moving neutral particles may

the eclipse effects on the two kinds of solar radiation, wireless observations on the equivalent height and reflection coefficient of either ionised region, continued through the eclipse period, are well suited to decide between alternative hypotheses as to the cause of their ionisation, since abnormal effects would be expected in either case, due to the temporary cessation of the production of ions. In the case of ultra-violet light this effect would be most marked in the region of the optical eclipse and immediately after totality, while in the case of neutral particles the maximum effect would occur earlier and in a different region.

In the solar eclipse of 1927 in Great Britain the experiments made by one of us have been interpreted as supporting the view that ultra-violet light is partly if not wholly operative in the lower region, since a partial return to night-time wireless conditions was experienced round about optical totality. But the possibility of fortuitous variations in the ionised layer cannot be entirely ruled out, and it is highly desirable that more numerous observations of a

FIG. 1.

be considered as possible causes. Because of the difference in velocity with which these two types of radiation travel, it turns out that there are important differences in the incidence in time and place for what may be called the 'optical eclipse' and the 'corpuscular eclipse', when the moon cuts off the solar stream from the earth.

In consequence of the motions of the moon and the earth, the stream of supposed neutral particles will be interrupted more than an hour before the ultra-violet light is stopped; the eclipse effect on the incidence of the neutral particles may, in fact, be entirely over before the optical eclipse begins. The eclipsed region in the case of the particles will also be much to the east of the optical eclipse track. The difference between the two eclipses, in time and space, will depend on the velocity of the particles; if this is assumed to be 1000 miles/sec., as suggested by E. A. Milne's theory of emission of solar particles, the difference in time is about two hours.<sup>1</sup>

In consequence of the marked difference between

similar character should be made. The known great variability of upper-atmospheric conditions renders it important that check observations should be made outside as well as inside the areas of both optical and particle eclipses.

We wish to direct attention to the excellent opportunity afforded by the solar eclipse of Aug. 31, 1932, for testing this point. By the courtesy of the Royal Astronomical Society, we are enabled to reproduce here a map (Fig. 1) made by Mr. J. C. P. Miller, in which the corpuscular eclipse on this occasion is indicated, on the above assumption as to the speed of the particles. The eclipsed region, at various times, and the central line, are shown; all the times are G.M.T. The shaded band is the track of optical totality. Special wireless observations at a site on the track of the optical eclipse are to be made in Canada under the joint auspices of the Canadian National Research Council and the Physics Department of McGill University, Montreal, but these should be supplemented by observations at as wide a network

of stations as possible within or near the belt of the corpuscular eclipse.

We shall be glad if anyone who is able to make observations of either a simple or more ambitious character on this occasion will communicate with the first mentioned below. In this connexion we may add that, in the case of the 1927 eclipse, wireless observations of great value were obtained with apparatus of modest character, a simple galvanometric record of signal intensity being obtained.

### Photodichroism Produced by $\alpha$ -Particles

A PHOTOGRAPHIC plate of specially prepared fine grain emulsion, exposed to plane polarised light, gives rise on development to a dichroic deposit of silver. This effect, discovered by Weigert,<sup>1</sup> appears to have a vital bearing upon theories of formation of the latent photographic image.

It would seem that a silver deposit might exhibit dichroism for one of two reasons: (a) the silver grains are scattered at random but are all oriented with their longest axis pointing in one direction, the direction of the electric vector of the original light which produced the dichroic image; or (b) the silver grains are oriented at random but are so distributed as to be arranged more densely in one direction than another, the direction of closest packing being that of the electric vector of the original light.

If it be held that the latent image is produced as a result of ejection of a photoelectron by the absorbed quantum of light, then the selective photoelectric effect, in which the emission is a maximum in the direction of the electric vector of the incident light, may be invoked to explain the Weigert effect, and the silver deposit will owe its dichroism to condition (b) above. Further, it might be expected that in the presence of a strong magnetic field parallel to the incident light, the production of dichroism might be diminished or destroyed. This effect was looked for by Cotton<sup>2</sup> without success, and accordingly he abandoned the explanation.

Although examination of the dichroic silver deposit with high magnification fails to show any evidence for either (a) or (b), as the grains are too small for complete resolution, yet it is possible to produce, artificially, a deposit of silver grains in which the distribution is linear and approximates to condition (b), by bombarding the photographic plate with  $\alpha$ -particles at a small glancing angle. With very fine grain plates each  $\alpha$ -particle produces a track<sup>3</sup> consisting of a number of silver grains depending upon the residual range on impact. The spacing of the grains in a single track varies, but on the average, for the particular photographic plate used, their centres are about 0.5 micron apart. They are in a medium (gelatine) of refractive index about 1.52, so that their separation is rather larger than a wave-length of yellow light, which is rather less than 0.4 micron in such a medium.

Seen under a microscope with a twelfth of an inch oil immersion objective and a magnification of 25, the individual grains in the  $\alpha$ -particle tracks are well resolved when the electric vector of the light by which they are seen is perpendicular, and poorly resolved when it is parallel to the length of the track. This is

well shown in the photomicrographs (magnification 1350 times) in Fig. 1. In other words, the light transmitted through the gaps between adjacent particles in the  $\alpha$ -ray track is polarised with the electric vector perpendicular to the track.

To test this further, a fine grained photographic plate was exposed for equal periods to an intense polonium source of  $\alpha$ -rays, so that on development two adjacent portions of the plate had silver deposits of equal density, one with the  $\alpha$ -ray tracks in one direction, and the other with the tracks in the direction at right angles to the former. The two deposits were thus formed of silver grains of which the directions of closest packing were mutually at right angles. Under these conditions it was possible to observe a very minute but distinct dichroism of the silver deposit, the optical density of the deposit being greater

when the electric vector of the incident light coincided with the direction of the  $\alpha$ -ray tracks, that is, with the direction of closest approach of the silver grains.

It is thus possible to produce dichroism with a known condition of arrangement of the silver grains, and it would seem that the second explanation of the photodichroism produced by excitation with plane polarised light is the correct one; this would lend support to the idea that the selective photoelectric effect plays a direct part in producing the photographic latent image. Further experiments are being conducted, and the results will be published in full later.

### Stark Effect for Argon

THE Stark effect on argon lines has earlier been investigated by E. Böttcher and F. Tuczek<sup>1</sup> and by W. Steubing.<sup>2</sup> These investigators have worked with relatively small electrical field strengths, 26 kv./cm. and 38 kv./cm. respectively, and could not observe any effect. Using higher field strengths ( $E_{\text{max}}$  about 170 kv./cm.), T. Takamine and N. Kokubu<sup>3</sup> succeeded in showing some very small displacements, towards the red of the violet lines, belonging to the so-called 'red spectrum' of argon, the structure of which was unknown at that time. The series analysis of this spectrum was given by K. W. Meissner<sup>4</sup> and F. A. Saunders.<sup>5</sup> From this we now notice that the affected lines observed by Takamine and Kokubu all belong to the principal series. It was to be expected that these lines would be very little displaced, whereas on the subordinate series lines a greater influence of the electrical field would be anticipated. Probably owing to deficient intensity, these lines have

not been observed. For this reason I made an attempt to investigate the electrical effect on these lines.

The source of light was a Lo Surdo tube of the same type as earlier described by me.<sup>6</sup> The light was analysed by a plane diffraction grating spectrograph, constructed by Prof. J. Koch. The grating, having an effective surface of 8 cm.  $\times$  5 cm., was ruled at the National Physical Laboratory at Teddington. Using autocollimation according to Littrow, the light from the slit was made parallel by a large Zeiss Tessar

FIG. 1.—Spectrum of argon (dispersion about 14 Å. per mm., magnification about 14), maximum field 92.7 kv. per cm.

with 60 cm. focal distance and by the same lens system focused on the photographic plate. Thus brilliant spectra were produced in the first and second order. One of the photographs obtained is reproduced in Fig. 1. The maximum field strength, as determined from the Balmer lines of hydrogen, present in the discharge tube, was 92.7 kv./cm. About ninety lines, belonging to the subordinate series, have been observed in the region  $\lambda\lambda 6500-5100$ , and nearly all of them show greater or smaller displacements, the main part of them towards the red.

Compared with the electrical influence on the analogous spectrum of neon that was earlier investigated,<sup>7</sup> the displacements of the energy levels of argon in electrical fields are considerably smaller. This is intimately bound up with the hydrogen differences. The diffuse subordinate series terms  $m d_i$  and  $m s_i$ <sup>(1)</sup>

(according to the notation of Paschen for the neon terms) have appreciably larger hydrogen differences than the corresponding neon terms. Thus the magnitude of the displacements is in agreement with the rule that greater displacements correspond to smaller hydrogen differences, and conversely. The greatest shifts are observed at the most hydrogen-like terms  $m d_2$ ,  $m s'_1$ ,  $m d'_1$ , and  $m d''_1$ , whereas the terms  $m d_6$ ,  $m d_5$ ,  $m s'_1$ ,  $m s''_1$ , and  $m s_1$  with the greatest hydrogen differences are the least affected. Among these terms the  $m d_6$  are quite unaffected. For the main part of the terms, the term value decreases in the electrical field. Only two of the observed terms,  $6d_5$  and  $5s_1$ , increase with the field.

The large hydrogen differences give rise also to another phenomenon predicted by the theory, namely, that the displacements of the terms are proportional to the square of the field strength. This may be observed at several terms. The general view of the Stark effect for argon is quite different from that observed in the helium or neon spectrum. In the latter, the diffuse series lines are accompanied on the violet side by combination lines of the type  $2p_i-mf$ ,  $2p_i-mg$ , etc., forming characteristic groups. There are no such groups in the argon spectrum. The position of the  $2p_i-mf$  lines may be computed from the known terms,<sup>8</sup> but no combination lines at all have been observed with certainty. Among the  $s_i$  terms ( $i=2, 3, 4, 5$ ) a great number have been investigated. They all decrease with the field strength and the displacements are remarkably large. The investigation is being carried on, and a more detailed account is to be published elsewhere.

#### The Auroral Spectrum in the Infra-Red

PROF. L. VEGARD<sup>1</sup> has recently reported the observation of two infra-red lines or band-heads in the auroral spectrum, namely,

a strong one at  $\lambda 7883 \pm 12$  Å.  $\nu 12682 \pm 20$  cm.<sup>-1</sup>,  
and a weak one at  $\lambda 8095 \pm 12$  Å.  $\nu 12350 \pm 20$  cm.<sup>-1</sup>.

Pointing out that, since the spectrum shows bands of the  $N_2$  second positive system strongly, it might also be expected to contain bands of the  $N_2$  first positive system, Prof. Vegard calculates the positions of three bands of the latter which are within a few Ångström units of the stronger auroral line  $\lambda 7883$ , and points out that one of the three corresponds to an improbable transition, but leaves open the question as between the other two.

The main object of the present letter is to correct the numeration used in Prof. Vegard's, and eliminate another one of the three calculated bands.

Poetker's observations<sup>2</sup> in the far red and near infra-red region of the first positive system required a revision of the vibrational quantum numeration first given by Birge<sup>3</sup> and now employed by Prof. Vegard. The correct numbering is obtained by diminishing Prof. Vegard's  $n_2$  by unity to give  $v'$ , his  $n_1$  being identical with  $v'$ . Birge's revised band-head formula<sup>4</sup> is

$$\nu_{\text{head}} = 9518.59 - (1718.40v' - 14.437v'^2 - \dots) - (1446.46v'' - 13.929v''^2 - \dots),$$

and the  $v', v''$  numeration of the three bands calculated

by Prof. Vegard is: 1, -1 ( $\lambda 7885$ ), 7, 6 ( $\lambda 7896$ ), and 12, 12 ( $\lambda 7863$ ). The first of these is meaningless. The third is improbable, since 12, 12 is remote from the course of the Condon intensity curve in the  $v', v''$  scheme of the band system. Only the 7, 6 band need therefore be considered. A band near the computed 7, 6 position was observed in  $N_2$  by Croze<sup>5</sup> at  $\lambda 7887$ ,  $\nu 12676$  and by McLennan, Smith, and Peters<sup>6</sup> at  $\lambda 7894$ ,  $\nu 12666$ ; both of which are within the observational error of Prof. Vegard's strong auroral line or band-head.

The  $N_2$  first positive band nearest to the weak auroral line or head,  $\lambda 8095$ , is the 6, 5 band observed by Poetker at  $\lambda 8047.2$ ,  $\nu 12423.2$ ; the difference is much bigger than the estimated error of observation of the former; this therefore remains unidentified.

The idea of the presence of  $N_2$  first positive bands in the auroral spectrum is not new. About ten years ago, I think, Lord Rayleigh (unfortunately I cannot now turn up the actual paper) suggested that the auroral line or band  $\lambda 6320.1$ ,  $\nu 15818$ , might be identified with one of the first positive bands which appear especially strongly in the spectrum of active nitrogen, namely, the 10, 7 band  $\lambda 6321.1$ ,  $\nu 15815.7$ .

### Sound-change and Indeterminism

THE recent tendency towards indeterminism which is apparent in the natural science of to-day raises the question whether it would not be equally profitable to adopt a somewhat similar attitude in considering the most difficult of all the problems of the science of philology: Why do changes in language take place? In this letter I wish to put forward the suggestion that, of those sound-changes usually known as 'spontaneous', in which one sound of a language (which we may call  $X$ ) gradually changes to another ( $Y$ ), some at least may be due to pure chance. At a given period in which the sound  $X$  is present in the language let us consider the pronunciation of the children learning to acquire this sound. While the majority will acquire a pronunciation  $X$  identical with that of the earlier generation, some will acquire slightly 'erroneous' pronunciations ( $X'$ ,  $X''$  . . . etc.), that is, pronunciations differing slightly from that of the majority.

In attempting to explain changes of the type considered here it is usually assumed that, at the moment when the change is commencing, there is some *a priori* reason (physiological or otherwise) why there should be a tendency towards a particular erroneous pronunciation; in this case towards a pronunciation  $X_1$ , erring slightly in the direction of the sound  $Y$ . I suggest, however, that the change can be explained without the assumption of such an *a priori* reason. We know, from the theory of probability, that, even if there is no such *a priori* reason, the erroneous pronunciations  $X'$ ,  $X''$  . . . etc. will not be equally represented. But so long as the number of speakers with any one of these erroneous pronunciations is not abnormally high, there can be no tendency towards a change in the sound  $X$  in the language as a whole. Suppose, however, that by chance we have an exceptionally high proportion of speakers with the erroneous pronunciation  $X_1$  (just as we might have an exceptionally long 'run' on one

colour at roulette), then in a comparatively short space of time the pronunciation  $X_1$  may become the prevailing one; in other words, a change of  $X$  to  $X_1$  will have taken place.

Let us now consider the conditions at this stage of the language. As before, there will be a certain proportion of speakers with erroneous pronunciations ( $X_1'$ ,  $X_1''$  . . . etc.); of these, let us consider two:  $X$  (which has now become erroneous) and  $X_2$  (erring still further in the direction of  $Y$ ). If the proportion of speakers with any one of these erroneous pronunciations is not abnormally high, there can be no tendency towards a further change. If the proportion of speakers with the erroneous pronunciation  $X$  is, by chance, exceptionally high, this may again become the prevailing one; in this case  $X_1$  will change back to  $X$ . If, on the other hand, the proportion of speakers with the erroneous pronunciation  $X_2$  is abnormally high, there may be a change of  $X_1$  to  $X_2$  and a stage nearer  $Y$  will be reached. Thus, given a favourable 'run', it may easily happen that finally  $Y$  itself is reached via the stages  $X_1$ ,  $X_2$  . . . etc. In this way the change of  $X$  to  $Y$  can be explained as being due to pure chance. Of spontaneous sound-changes, therefore, some may be due to an *a priori* cause and others to pure chance, and the latter possibility should always be borne in mind in the investigation of these changes.

### Crystal Lattice Distortion in Stretched Wire

THE process of cold-rolling or drawing certain metals is known to produce a permanent irregular departure from the normal atomic structure of the grains. I find that this type of lattice distortion occurs also in wires of constantan which have been stretched longitudinally by gradual loading. The degree of the distortion increases most rapidly as the yield-point is approached. Nickel, copper, and most alloys examined give similar results.

The criterion of true lattice distortion is a broadening of the lines in the X-ray spectrum formed by reflection of monochromatic X-rays. A change in breadth is indicated in a sensitive manner by the state of resolution of the  $K\alpha_1$ ,  $\alpha_2$  components of the incident radiation. The  $\alpha_1$ ,  $\alpha_2$  doublets reflected by the (420) and (331) planes of constantan, photographed under identical conditions, are shown herewith. Fig. 1, A, is taken of the initial wire; and Fig. 1, B and C, of the wire under increasing load. It is clear by comparison that as a result of the tension the doublets in Fig. 1, A, diffuse into unresolved bands, and thereby illustrate the production of lattice distortion. This structural change will call for some consideration in any theory of the changes of properties of wires under tension.

A simple practical proof that these observations indicate lattice distortion and not a very fine-grained structure, which also causes diffusion of X-ray spectra,

FIG. 1.

has been highly desirable. Such evidence is provided by Fig. 1, B, where (1) the (420) is diffused even while the (331) line is still a sharp doublet, despite the addendum (2) that the (331) occurs at the small reflection angle where the resolution on geometrical grounds is much less. Now this means, on the small crystal theory, that the dimensions of the grains in the [331] directions are large ( $c 10^{-4}$  cm), whilst in the [420] directions they are very small ( $c 10^{-7}$  cm). These two aspects are mutually contradictory. Therefore the small crystal hypothesis is here untenable.

A similar differential resolution of the doublets has been found well marked in rolled  $\alpha$ -brass

### The True Weight of Benzopurpurin 4B, and the Electrical Conductivity of its Aqueous Solutions

A PAPER has recently been published by Robinson and Mills<sup>1</sup> in which certain properties of Benzopurpurin 4B are precisely defined. The concentration of the solutions has been determined by these authors by drying in an oven at 105° C.

The purpose of this communication is to point out that many direct cotton dyestuffs are so extremely hygroscopic that one or two per cent of moisture remains at this temperature. In the course of exact work in this laboratory on the absorption of direct dyestuffs by cellulose, Benzopurpurin 4B (amongst other dyes) has been prepared in a pure state, and the apparent dry weight determined under various conditions, with results of which the following are typical

|                                                   | I     | II    |
|---------------------------------------------------|-------|-------|
| Relative wt air dry                               | 113.6 | 114.4 |
| „ „ dried in 110° oven for 24 hours               | 101.7 | 101.5 |
| „ „ dried at 110° C <i>in vacuo</i> over $P_2O_5$ | 100.0 | 100.0 |
| „ „ in 110° oven again                            | 101.5 | 101.7 |

The moisture content of this substance, and of the other direct dyestuffs so far examined, appears to vary continuously with the relative humidity of the surrounding atmosphere (R.H. in 110° C oven is of the order 1 per cent). It appears, therefore, that the electrical conductivities and other constants given by Robinson and Mills will be in error by about 1.9 per cent, the approximate moisture regain at 105° C.

The general principles of the drying of hygroscopic substances at high temperatures are illustrated in a paper, "The Dry Weight of Cotton", by Davidson and Shorter<sup>2</sup>

### Formation of Periodic Precipitates in the Absence of a Foreign Gel

RECENTLY many workers<sup>1</sup> have reported on the formation of periodic precipitates in the absence of another gel. We have obtained periodic precipitates in the slow coagulation of sols of ferric hydroxide, chromic hydroxide, and stannic hydroxide by small quantities of univalent electrolytes like potassium chloride and sodium bromate. Freshly precipitated ferric hydroxide was peptised by the minimum quantity of acetic acid, which was then boiled off, the sol was further purified

by hot dialysis. The concentration of the purified sol was 39.2 gm per litre. The chromic hydroxide sol was obtained by adding ammonium carbonate solution to hot chromic chloride and then purified by continuous hot dialysis. The concentration of the purified sol was 32.5 gm per litre.

We obtained the stannic hydroxide sol by peptising stannic hydroxide (freshly precipitated from stannic chloride and freed from chloride) with ammonia and afterwards driving it off by boiling. The sol contained 12.4 gm of  $SnO_2$  in a litre.

These observations can be explained from the theory of periodic precipitation given out by Dhar and Chatterji.<sup>2</sup> The theory states that periodic precipitation is caused by the adsorption of the sol by the precipitate of the same substance, hence, according to this theory, periodic bands are obtained only when the sol and the precipitate co-exist. In the present case, when the sol is coagulated slowly by the addition of small quantities of univalent electrolytes, the sol and some of the precipitate coagulated from it exist together for a sufficient length of time. Hence adsorption of the sol by its precipitate occurs, giving rise to periodic bands. On the other hand, when the sol is rapidly coagulated by the addition of large quantities of electrolyte, the sol soon passes from the sol to the precipitate condition. The sol and the precipitate thus do not co-exist for a sufficient length of time. Hence no ring formation takes place.

It will be interesting to note in this connexion that we could not obtain periodic precipitates by the coagulation of the same sols with polyvalent electrolytes.

### Winter in the Ionosphere

IN a recent Geophysical Discussion at the Royal Astronomical Society,<sup>1</sup> I suggested that there is evidence of a close connexion between the mechanisms of ionisation of the Kennelly-Heaviside and Appleton regions of the ionosphere. The evidence depends on coincidences in the annual variations of received long and short wave signals.

Hollingsworth<sup>2</sup> reported a very abrupt change in received signal intensities measured at Slough, Manchester, Glasgow, and Aberdeen, and in polarisation measured at Slough, on wave-lengths of more than 10,000 metres, "during the last week of October and the first week of November 1924". The new mean values attained at this onset of the radio winter were maintained "until the beginning of May 1925", although the May change was much less spectacularly abrupt than the November change. The phenomenon, which I have called the Hollingsworth anomaly, was repeated at the end of October 1925, and it was shown that the primary characteristic of the radio winter is the persistence of abnormal polarisation throughout the hours of daylight.

Wilkins, observing here daily from July 1931, was receiving radio telephone signals from Rome and Sardinia on the ultra-short wave-lengths of 10.06 metres and 9.8 metres respectively with fair regularity until Nov. 1, 1931. From that date no signals in the ten-metre region were heard, despite daily observation.

Hollingsworth was undoubtedly dealing with waves returned from the lower parts of the Kennelly-Heaviside region—he had in fact measured the equivalent height of reflexion as about 75 km—and Wilkins was almost equally certainly concerned with an electron

limitation effect in the upper part of the Appleton region, the electron density even in the most heavily ionised part of this region having become insufficient to 'reflect' the very high frequency waves even at grazing incidence. My suggestion was, then, that the very striking coincidence in date between the two phenomena pointed to a similarity in the mechanism of ionisation in the two regions, which must not be overlooked in discussion of the rival claims of ultra-violet light and corpuscles as the effective agents for one region or the other.

The argument is now very notably reinforced by the fact that Wilkins again heard the 10.06-metre signals from Rome, and heard also signals on 10.02 metres from Oslo (the third harmonic of a telegraph station) on May 2, 1932, daily observations throughout the ionospheric winter thus so accurately delimited having failed to give any trace of signals between Nov. 2 and May 1. The signals from Sardinia (9.8 metres) reappeared on May 6. We are without detailed long-wave data for 1931-32, but it should be remarked that 1924-25 and 1931-32 are approximately symmetrically disposed about the somewhat indefinite 1928-29 maximum of the present solar cycle, so that the comparison here made is the next best thing.

It would be unwise to infer forthwith an identical mechanism for the two regions, but clearly both involve agencies of solar origin, and both have curves of annual variation in which a six months' 'summer' gives place to a six months' 'winter', and vice versa, on dates common to the two regions. The dates are somewhat oddly displaced relatively to the astronomical reference points of solstice and equinox, yet they suggest a twelve-monthly variation rather than one related to the two equinoctial maxima of magnetic disturbance.

### The Tectonics of the Albertine Rift

It has been represented to me that misconception with regard to this matter, so far as my own views are concerned, may arise in consequence of my passing, without comment, some remarks made by Prof. J. W. Gregory in his able review of Prof. Bailey Willis's book, "Living Africa".<sup>1</sup> Gregory quotes my early description of the local rift valleys correctly thus: "fracture valleys running along linear upwarps".<sup>2</sup> That was the view I put forward in 1921, but we have learnt a good deal since then, and Sikes pointed out to me, in 1925, that the faults I invoked to explain the Albertine rift are of a type difficult to accept, because of the immense depths from which they would have to emerge. I agreed; but this in no way weakened my general thesis. Writing to my friend Prof. Arthur Holmes, I afterwards suggested that the rift fractures rose from nearly flat soles, after the manner of the highland thrusts, but he at that time was unable to agree, and I delayed publishing this view until further evidence should be forthcoming, and then, in 1928, Bailey Willis produced his ramp hypothesis to explain the Dead Sea Valley—an explanation more complete but essentially similar to that which I had suggested to Holmes to account for the Albertine depression and the high scarps bordering it. I adopted the ramp explanation, as I stated, in Pretoria in the following year.<sup>3</sup>

That the Albertine Rift did not originate along the crest of a linear upwarp has now been clearly demonstrated by our studies of the riverine history of

Uganda, for it is found that the eastward drainage away from the present escarpment did not commence until the rift valley appeared, and is an inversion consequent upon the uprise of the valley sides, nor did this occur at the inception of the rift. The main reversal indeed was not until late-middle or post-middle Pleistocene times, when renewed movement gave us the present scarp topography.

It is interesting to note that further evidence in support of the compression hypothesis is provided by recent petrological studies. It is brought out by Holmes and Harwood's work on "The Petrology of the Volcanic Fields East and South-East of Ruwenzori, Uganda",<sup>4</sup> and still more strikingly by A. W. Groves in some as yet unpublished work on rocks in the rift valley zone in Uganda, wherein he shows that crushing becomes increasingly pronounced as the rift is approached, and reaches its maximum in mylonisation in the neighbourhood of the faults. I have Dr Groves's permission to mention this.

### An Inherited Abnormality in Rhode Island Red Poultry

A SEMI-FEATHERLESS condition, associated with dwarfism, occurs in several breeds of poultry. It is usually attributed to some food or vitamin deficiency. Dakin and Hamilton described specimens in 1928 and suggested that the condition might be due to sub-thyroidism.<sup>1</sup>

In 1929 certain facts suggested to us that the abnormality might be an inherited character, and breeding experiments were undertaken. Three Rhode Island Red males of this type were reared and at about eleven months old appeared to be practically normal. They were mated to normal hens and produced chicks of both sexes showing every conceivable degree of the abnormality. Some were almost completely naked even at six months old, whilst others seemed almost normal throughout. Both sexes showed the abnormality, but the most extreme cases were nearly all males. All the extremely abnormal specimens died, but the less abnormal of these  $F_1$  individuals survived, and the best of the females were mated to a male from a normal stock. This mating also produced chicks of both sexes showing every degree of abnormality. The worst of the  $F_1$  females which survived were mated back to the parent cock to test whether such a mating would produce living offspring. The percentage hatched was as high as in a normal stock, and again every conceivable degree of the abnormality was produced.

That the condition is not due to infection or other environmental factor is practically certain, for a few birds from an unrelated stock, hatched and reared at the same time under the same conditions, showed no sign of the abnormality. It appears certain, therefore, that the condition is inherited, but the exact mode of its inheritance is not yet known. It is apparently not sex-linked.

## Research Items

**Ancient Egypt and Medieval Europe.**—Interesting parallels are drawn between certain customs of ancient Egypt and those of medieval and even modern Europe by Mr L B Ellis in *Ancient Egypt*, 1931, pt 4. The 'rearing feast' given to workmen in Westphalia by the owner of a newly erected house, finds its counterpart in the sacrifice offered in ancient Egypt for the workmen who had built a tomb. The splendour of the burial equipment of Tut-Ankh Amen is not far removed in spirit from that which was responsible for the burial of Henry II of England, according to Matthew Paris, in royal robes, crown, ring, gloves, boots of gold-work, gilt spurs, and sceptre and sword, while a bishop or abbot was buried in full vestments, and a bishop of the eleventh century had with him his liturgical comb, with which he had smoothed his beard as he approached the altar. The use of the canopic jars for the storing of the viscera is paralleled by the separate burial of the heart and of the viscera of Eleanor of Castile, and of the heart of Prince Arthur, son of Henry VII. The desire of the medieval devout to be buried, or to have a tomb, in Palestine, takes the form in Egypt of burial at Abydos, or failing that, the erection of a tomb or stele. The concern for burial in both instances is shown in the arrangement for the tomb during lifetime, as Henry VIII contracted with Torrigiano for his tomb in Westminster Abbey. The effigies on Egyptian tombs show grandparents, parents, children, grandchildren, friends, and even a favourite dog. On Elizabethan and Jacobean tombs, married couples appear with their progeny, even those who have died in infancy. Similarities in funerary inscriptions are very close, even when the Egyptians compare themselves with their gods. Rekhmara was "Thoth in judgment, the image of Ptah, the equal of Khnum", while Lady Cope D'Oyley, ob 1633, was "Rebecca in grace, in heart an Abigail, in works a Dorcas, for the church a Hanna, and to her spouse Susanna, prudently simple, providently wary, to the world a Martha and to Heaven a Mary".

**Cuna Indians' Conception of the Soul.**—The significance of certain words current in the religious and magical beliefs of the Cuna Indians of Panama has recently been discussed by Baron Erland Nordenskiöld (*J. Americanistes*, N S, 24). One word, *purba*, may be translated soul, but it has a multiplicity of meanings. It, or rather an aggregation of *purbas*, is a man's double, and leaves his body at death. A very old chant speaks of a man's *purba*, and of the *purbas* of his hair, his fingers, his heart, etc., leaving the body while his *purba* sits at the foot of his hammock weeping. Innumerable dangers assail it on its journey to the Empire of the Dead, where it lives for the future very much the same life as on earth, but in better and happier conditions. In some cases of illness the *purba* is carried off by demons to the home of the demons, and unless it is brought back in time the patient will die. It is common for the Kuna to speak of events witnessed by the *purba* during sleep. Thus one man saw his daughter, who had died while quite young, and, with her, her five children who had been born in the spirit world. Animals have *purbas* which are generally men, though sometimes they are animals. The *purbas* of plants are women. Stones, the sun, and other inanimate objects have *purbas*, and the *purbas* of books, newspapers, etc., burnt in front of the hut of a sick man serve to divert the attention of evil spirits who come to do him harm.

**Feeding Habits of the Zebra-fish.**—In the first number of this year's *Bulletin* of the New York Zoological

Society (vol 35, p 31), C M Breder gives an account, illustrated with photographs of the manoeuvres of the zebra-fish (*Pterois volitans*) of the Indian Ocean in capturing prey. On the introduction of a small fish into its tank, the fish, which is vertically striped with black and white, began to wave its long exerted fin-rays, very slowly and not in unison. When the small fish came to investigate, and was in most favourable position in front of its foe, it was snapped up. Later on the zebra-fish took a more active part and would itself approach prey, waving its fin-rays, the prospective victim did not move off, but swayed from side to side in the water as if dying. This went on until the two were about an inch apart, when the small fish was seized by its foe, from which it might easily have escaped, as the zebra-fish is not adapted to active chasing. The explanation of this behaviour on the part of the prey may perhaps be the dazzling effect of a pattern of narrow stripes, which affects even the human eye, and in this connexion it may be noticed that the barred pattern in hawks is especially characteristic of the active bird-killing genera, and is rare among those which feed on prey where dazzling would be ineffective.

**Sex-linked Inheritance in Ducks.**—Having previously shown how the facts of sex-linkage in fowls could be turned to economic account, Prof R. C. Punnett (*J. Genetics*, vol 25, No 2) has now found that the same principle can be applied to the breeding of ducks. When the common mallard (*Anas boschas*) is crossed with the Indian runner duck, the male ducklings are uniformly of a darker olive-brown than the females, thus enabling the sexes to be distinguished at an early age. When the mallard is the male parent, the ducklings of both sexes are alike and resemble the mallard. The  $F_2$  from this cross gave two male dark brown, one female dark brown, one female light brown. The runner duck came from the East nearly a century ago, and differs markedly from the mallard in body-shape and carriage. It lays many eggs but does not brood them, while the broodiness of the mallard is dominant in the  $F_1$  birds, as is also its habit of taking to flight. The runner is not observed to fly (see also NATURE, 126, 757, Nov. 15, 1930).

**New Observations on *Cephalodiscus*.**—Up to the present, sixteen species of *Cephalodiscus*, some of them of doubtful validity, have been described. The *Discovery* Expedition collected examples of five species, two of which are described as new by C C John (*Discovery Reports*, 3, 223-260, 1931). The greater part of this material was obtained in the neighbourhood of the Palmer Archipelago, the Falkland Islands, and South Georgia. The observation of Andersson (1907) that the living zooids of *Cephalodiscus* come out of the coenocœcium and creep, using the disc as a sucker, on the surface of the colony is confirmed by observations made on living specimens by Dr Stanley Kemp. Two kinds of zooids are present in *C. hodgsoni*—red zooids, with twelve arms, which are females, and brown zooids, with ten or eleven arms, which are males. In *C. densus* a gill sac lies between the external gill opening and the pharynx. The collar pores, which have thick walls and are ciliated, lead by short canals into their respective collar cavities and control the water-currents which maintain the turgidity of the collar and arms. The author notes that during the development of a bud the notochord is very conspicuous. In *C. densus* the heart is situated not on the tip of the notochord, as in *C. dodecalophus*, but on its ventral

surface, so that the pericardium extends backwards almost parallel to the notochord. The evidence suggests that the dorsal vessel, which gives off two branches—the pharyngeal vessels—which enter the gills, conveys blood from the heart to the gills, arms, and proboscis, and that the ventral vessel returns blood to the heart. An account is given of the details of the vascular and nervous systems and of the characters of the four subgenera (one new) and of the eighteen known species. It would have been helpful to the reader to have the magnification of the figures stated.

**Spike Disease of Sandal**—A study of the initial infections of spike disease in a large number of sandal plantations suggested that proximity to cultivated land tends to bring out the disease ("Investigations on the Spike Disease of Sandal, III—Report of Progress to Sept 30, 1931" Indian Institute of Science, Bangalore). This suggested a study of the host range of the disease, and a wide variety of plants is being raised for this purpose. Entomological work has taken the unique form of compiling a list of some eight thousand species of insects normally found on the sandal tree, their relation to the disease in question has yet to be tested. Laboratory experiments show that arginine and cystine are present in greater quantities in healthy plants than in diseased, whilst histidine and lysine are less abundant in the healthy specimens. The pamphlet is intended primarily as a progress report for forest officers, but more technical details of the work will ultimately be published in the *Journal of the Indian Institute of Science* or in other scientific periodicals.

**Enzyme Distribution in Growing Tissues**—The micro-method of measuring minute quantities of amino-acid recently developed by Kinderström-Lang and Holter has now been applied by them (*C R Lab Carlsberg*, 19, No 6) in determining the rate of breakdown of peptides by sections (200  $\mu$  thick) cut from the roots of germinating barley. Their results are of considerable interest in that they show a maximum rate of peptide hydrolysis about 0.8 mm behind the root tip, that is, in the region of elongation. This result is obtained when either leucyl-glycine or alanyl-glycine is employed as substrate, but the rate of hydrolysis of the former decreases more rapidly than that of the latter. In barley leaves, on the other hand, peptidase activity was less and also less variable, but it showed a steady increase from the tip of a leaf to its base.

**Recent Earthquakes in the United States**—*Earthquake Notes*, for Dec 1931, issued by the Eastern Section of the Seismological Society of America, contains some brief notes on recent earthquakes in the United States. The most important shock was that of south-west Texas on Aug 16, 1931. Though the maximum intensity, observed at Valentine, did not exceed 8 (Rossi-Forel scale), slight damage occurred over a large district, and the shock was felt over an area of nearly 450,000 sq miles, of which rather more than half lay in Texas and the rest in Mexico. The first analysis of the seismograms places the epicentre in about lat 29° 9' N, long 104° 2' W, or fifty miles or more to the south-east of Valentine. The Western Ohio earthquake of Sept 20, 1931, had an intensity 7 at Anna, Botkins, and Houston, and disturbed an area of about 40,000 sq miles. From a study of the few seismograms available, Father Johat, S.J., found the epicentre to lie on the south side of, and close to, Anna.

**Effect of Pressure on Weston Standard Cells**—The effect of pressure on the e.m.f. of the Weston cadmium cell, which was investigated up to 1000 atmospheres

by Cohen and Sunnige in 1909, has been followed up to 12,000 atmospheres by T. C. Poulter and C. Ritchey (*Phys. Rev.*, March 1). The experiments, which were carried out in pressure cylinders with cells contained in glass, beeswax, or rubber, confirm the older work well over the common range of the two investigations, a pressure increase from 1 atmosphere to 1000 atmospheres is accompanied by a rise in e.m.f. from 1.018 to less than 1.026 volts. For higher pressures, the results for both 20° and 30° C lie on a single smooth continuation of the initial curves up to about 4000 atmospheres, but beyond this, while the 30° curve continues on its original course, the 20° curve rises much less rapidly, and shows little change in e.m.f. between 6000 and 10,000 atmospheres. Insufficient data exist to correlate the changes with the properties of the components of the cell, but it is clear that the effect can be neglected for most ordinary conditions of operation.

**The Hall Effect in Weak Fields**—The first part of the physics section of vol 2 of the *Memorie* of the Royal Academy of Italy contains a memoir by Drs M. Cantone and E. Bossa on the Hall effect, particularly in weak magnetic fields. The fields are provided by coils without iron and range from 0.020 to 800 gauss, the field of the earth being compensated. The Hall effect is amplified by the use of valves and can be measured to  $10^{-10}$  volt. In neither iron nor nickel is the effect proportional to the field below 6 gauss, but above this field the increment of the effect is nearly proportional to the increment of the field. Neither the two metals nor their alloys show hysteresis in the effect. For four samples of bismuth, for tellurium, antimony, silver, gold, platinum, palladium, aluminium, cadmium, zinc, tin, lead, tantalum, and magnesium, proportionality of effect and field holds from 0.020 to 800 gauss, while for copper, particularly if heated to a dark red and slowly cooled, proportionality ceases at 20 gauss. Compression of iron or nickel produces little change of the effect at low fields but a considerable change at high X-rays produce considerable change of the effect in non-magnetic metals.

**A Large Permanent Magnet**—Most of the work on the separation of  $\beta$ -rays into groups with definite energies has been done by curling up their paths in the field of an electromagnet, but now that cobalt steel, with its special properties, is available, it has become practicable to use permanent magnets, and the design of an instrument for this purpose has been published by J. D. Cockcroft, C. D. Ellis, and H. Kershaw (*Proc. Roy. Soc.*, April). It looks like an ordinary large electromagnet superficially, but the magnetising coils are used only to produce the desired remanent magnetisation. The weight is one ton, and with an air gap of 5.5 cm and pole faces of 500 sq cm area, a maximum field of 2300 gauss is obtainable. The initial expense is greater than for a similar electromagnet, but there is considerable subsequent saving in power. So far, it has been used only for fields of a few hundred gauss, which it has held constant to better than one part in two thousand for several days. The great advantage of the instrument for radioactive work is that it obviates the laborious control of the current of an electromagnet, but, from the account given, it also appears to be as easy and rapid to change fields with this as with the electromagnetic type.

**Spontaneous Ignition Temperatures**—An important symposium on this subject took place recently at the Institution of Petroleum Technologists. Mr F. A. Foord, Air Ministry, described the experiments carried out by Messrs W. Helmore and F. C. Code Holland, at the Royal Aircraft Establishment, on the ignition

characteristics of liquid fuels and chemical factors tending to accelerate their combustion. Although their conclusions were on the whole indefinite, they have shown that the problem bristles with difficulties no less complex than those associated with detonation, on which so much work has already been done, they stated, however, that the spontaneous ignition temperatures of heavy fuels are one of the chief factors affecting smooth running, ease of starting, and the general life of the engine in which they are used. Mr J. L. Chaloner gave an account of the determination of these temperatures by various German investigators in the past, and showed that, summarily, there seemed to be considerable divergence of opinion as to whether they were indeed any criterion of the behaviour of a fuel in an engine, with specific reference to the fuel knock, obviously, in methods of experiment differing so widely as they have done, it is difficult to arrive at generally acceptable conclusions, while even the merit of the Jentzsch tester, the only developed type of spontaneous ignition meter available, has been called into question. Mr L. J. Le Mesurier made useful comparisons of these temperatures with starting and ignition delay tests in engines, and insisted on the essential need of developing a flexible design of testing unit to ascertain its behaviour under all possible conditions, with the view of accumulating data for setting up requisite standard test conditions covering each broad class of commercial engine.

**Precision Photographic Equipment**—The firm of Leitz has recently made considerable improvements in the Leica camera. This little camera takes 36 pictures on one spool of standard-sized cinematograph film. Each picture is 36 mm  $\times$  24 mm. In the latest model, a focal-plane shutter is fitted, this is auto-

matically wound up when the film is moved for the next exposure, so that double exposures are impossible. Interchangeable lenses may now be obtained varying in aperture from  $f$  2.5 to  $f$  4.5 and in focal length from 3.5 cm to 13.5 cm. In addition to a direct vision view-finder, a tiny range-finder is fitted on the camera itself. The range-finder is coupled to the focusing mechanism of the lens, so that while the range is determined the camera is automatically focused. This coupling arrangement operates for each of the interchangeable lenses. A 'depth of focus' scale is engraved on the mount of each lens so that the depth of sharp definition at any distance and setting of the diaphragm is indicated. There should now be no difficulty in obtaining film packed specially for this camera, as both the Kodak and Selo companies are issuing film wound on special spools, and one of them is packing the film on spools which admit of daylight loading and unloading. A very extensive series of accessories specially designed for the Leica camera includes developing apparatus, printers, enlargers, projectors, stereoscopic attachment, and many others. Three accessories deserve special mention: after unscrewing the lens and its mount, the camera may be attached to a microscope in such a way that visual focusing may be carried out up to the moment of exposure; with another set of apparatus, photographs of small objects may be made at natural size, half size, or one-third size; lastly, a special apparatus for taking snapshots of surgical operations can be supplied, this is arranged with a special telescopic view-finder so that, after previous setting, the apparatus may be carried towards the object until the latter is sharply defined in the view-finder, the camera is then in focus, and its field of view is exactly the same as that observed in the finder.

### Astronomical Topics

**The Delporte Planet**—A Science Service *Bulletin* of April 18 describes the views of Drs F. L. Whipple and L. E. Cunningham on this object. They have obtained a value of the period as approximately 3 years, which does not differ greatly from Dr. Kahrstedt's value of  $2\frac{3}{4}$  years. But they prefer to call it a comet, not a minor planet, on the ground of its rapid decline in brightness, which certainly was much greater than would be expected in a planet. They still suggest that the body is identical with the comet Tuttle-Giacobini, seen in 1858 and 1907. The writer of this note held a similar view when the body was first discovered, but has abandoned it, on the ground that the observations of the comet of 1858 will not admit of a period much less than six years, while the present period is less than three years. Jupiter is the only planet that could produce such a great change of period, but if Jupiter had been the cause of the change, the orbit would still pass close to Jupiter's orbit, which it does not. The least distance between the orbits is about two units.

**Mars during the Last Two Oppositions**—*L'Astronomie* for April contains a paper with this title, by M. E. M. Antoniadi, whose long-continued studies of this planet are well known. He notes that there were some nights of superb definition. That of Sept. 20, 1909, was the best within his experience, his view of the planet with the great Meudon refractor on that night is described as a veritable revelation. The region to the south of the Syrtis Major had the appearance of being clothed with herbage, some regions, resembling forests, had a darker hue, the whole being studded with small white dots. Reference is made to a similar description by Prof. Barnard, using the Lick

refractor, in 1894, and it is stated that fine detail has also been seen at Mt. Wilson. The article is illustrated with numerous drawings, which bring out certain changes that were noticed in various regions.

**Greenwich Observations, 1930**—This annual volume has recently been published, it does not contain any change of system as compared with preceding years. The new sidereal clock, Shortt No. 3, was brought into use on April 1, its daily gaining rate was then 0.12<sup>s</sup>, it diminished steadily to 0.06<sup>s</sup> at the end of the year. The time service is based on observations with a small reversible transit instrument, reversed on every star, as the time derived from the transit-circle appears to have a systematic error. The reductions were carried out to 0.001<sup>s</sup>, and included the short-period lunar nutation terms, the star-places of Prof. Enchelberger's catalogue were used. The mean correction to the tabular longitude of the moon (Brown's tables) was +5.08" from observations of the limb, and +5.40" from observations of the crater Mosting A. The correction for the sun (Newcomb's tables) was +1.64".

Observations of solar flocculi with the spectro-helioscope form a new section of the volume, the quantities given are radial velocity, size, and distance and direction from neighbouring sunspots, also the distance of these from the central meridian, observations were made on 65 days, beginning with April 10. The volume also contains the magnetic observations, made at Abinger, and the meteorological observations. There are also measures of 176 double stars, observed with the 28-inch equatorial between 1922 and 1931, all were observed on at least three nights.

### Scientific Management in Industry

FEW documents can give a clearer idea of the ramifications of rationalisation in industry to-day than the annual Report of the International Management Institute (2 Boulevard du Théâtre, Geneva). The Report for 1931, which has recently been issued, although confined to the work and internal administration of the Institute, indicates that in spite of the difficulties created by the economic depression, the interest in scientific management and rationalisation is steadily expanding and the Institute's endeavours to realise the resolutions of the World Economic Conference of 1927 are having important results.

The relation of rationalisation to the economic crisis has attracted much attention, and, in Austria, Dr Ernst Streeruwitz has issued an important survey of rationalisation in relation to world economy, while the urgent need for economy in many quarters has raised the question of extending rationalisation methods to public administration. The drastic curtailment of public expenditure since 1930 has in many countries taken place on unscientific and hazardous lines, and the reductions are likely, while seriously decreasing the efficiency of the public services concerned, to produce no lasting economies.

Practically no machinery yet exists for the comparative study of public administration, and in most countries the idea of a special planning section continuously engaged in the improvement of great departments of State has yet to be born. Even in large scale industry, knowledge of the principles of organisation and administration is often only superficial. Useful activities are curtailed, while waste which would pay their cost many times over proceeds elsewhere unchecked. Even in the twentieth century, administrators still tend to perform surgical operations with an axe rather than with a scalpel.

The value of the Institute in this field, where widespread research is urgently required, is illustrated by the fact that the Institute receives every month more than 800 periodicals dealing with every phase of rationalisation in every country of industrial importance, and in addition, some hundred books and pamphlets are added monthly to its library. The analysis of these sources of information enables the Institute to avoid the incompleteness which characterises some of the reports included in "The Social Aspects of Rationalisation", issued by the International Labour Office.<sup>1</sup>

Certain aspects of the work of the Institute, including its association with the World Social Economics Congress at Amsterdam, its own annual discussion conference, and with the Department of Industrial Co-operation, organised for the first time under Section E at the centenary meeting of the British Association, have already been noted in our columns. In addition to this, various publications dealing with "Scientific Management in a Small Group of Factories", "Railway Systems their Organisation and Management", etc., have been distributed to members, and work has been carried out for the League of Nations, the International Labour Office, the International Committee for Scientific Management, the International Federation of Consulting Engineers, and the International Chamber of Commerce.

The report demonstrates clearly that there is a widespread and definite desire for an international clearing-house of information on rationalisation. Within its narrow resources, the Institute has greatly increased the efficiency with which it is meeting that need, and the work has been increasingly accomplished by means of subscribed income. The limits of administrative economy have, however, been reached, but it appears almost certain that with continued support from its founders for a further five years, the Institute should become self-supporting so far as its general services are concerned.

The continued services of the Institute are of real importance for the more rational arrangement of the world order in the interests of the general community. As the report rightly observes "Only by patient research leading to the gradual enlargement of exact knowledge can the world hope to win a more perfect control over the economic organisation of the machine processes which progress in the physical sciences has developed so rapidly during the past century." To persuade men of all nations to adopt a more scientific outlook on economic problems is the fundamental purpose of the Institute, and, forbidden by its statutes to participate in current political controversies, it has sought to facilitate the discovery of the essential facts or laws of the situation upon which alone, and not on political theory or dogma, a modern industrial community can effectively organise its social and economic life.

### The Idu (Japan) Earthquake of 1930

IN the accompanying map (Fig. 1), the principal faults formed during the Idu earthquake of Nov. 26 are indicated by broken lines, the most important being the Tanna fault, running nearly north and south. In the Tanna tunnel that crosses the fault 525 ft below the surface, the west side was shifted 7 ft 10.5 in to the south relatively to the other side, the movement on the surface, however, being distinctly less. In the recent number of the *Bulletin of the Earthquake Research Institute* (vol. 10, pp. 261-263, 1932), the results obtained from the renewal of the trigonometrical survey are given. The earlier survey was made in 1925-26, the later in Feb.-March 1931, so that the displacements measured may fairly be attributed to the Idu earthquake. They are represented in direction and magnitude by the arrows on the map, and they show that, as in the Californian earthquake of 1906, both sides were displaced, the west side to the south and the east side to the north.

Near the middle of the Tanna fault, the triangulation point at Daiba on the west side was shifted 28 in to the south, and that at Kurodake on the east side 39 in to the north, the sum of the two displacements being 5 ft 7 in. It is worthy of notice that during the previous interval, 1884-1925 (including the Kwanto earthquake of 1923), the whole peninsula drifted to the north, the point at Sano being displaced 103 in to N 70° E, that at Daiba 24 in to N 7° W, that at Osaka 46 in to N 18° E, and that at Enasi 48 in to N 47° E.

Some very interesting observations have recently been made by Mr. R. Takahasi on the movements of crust-blocks in the Tanna tunnel (*Bull. Earthq. Res. Inst.*, vol. 9, pp. 435-453, 1931). The object of his measurements was to determine if movements of the crust-blocks continued after the great earthquake, possibly with some of the numerous shocks that followed it. Bench-marks were fixed to

the concrete wall of the tunnel, in both west and east sections, at intervals of 20 metres, and their displacements were measured on six occasions, the last four series (on Feb 5-12, March 3-9, April 13-18, and July 18-24, 1931) being the most accurate. Though the changes are very minute, the curves that represent the displacements are remarkably similar. It is interesting also to notice that the principal changes occur in the sections crossed by faults or in which the strata suddenly change in strength, such weak lines forming the boundaries of crust-blocks.

FIG 1

It has long been known that an earthquake may be destructive on the surface ground while, in a tunnel below, it may pass almost, or quite, unnoticed. Mr N. Nasu has recently provided us with some useful measurements on this subject (*Bull. Res. Inst. Earthq.*, vol 9, pp 454-472, 1931). During the Idu earthquake, a few cracks were made in the walls of the Tanna tunnel. Otherwise it was unharmed, though in a village above, 55 per cent of the houses were destroyed. Mr Nasu placed two similar seismographs, one in the tunnel and the other on the ground above, the rock being of the same nature at both places. During the six months that followed, fourteen strong or moderately strong shocks were recorded.

If the period of the vibrations was less than one second, the amplitude was always more than twice, in one case 4.8 times, as great on the surface as in the tunnel. If, however, the period was as much as 4 or 5 seconds, the amplitudes at both stations were almost exactly equal.

Prof. Imamura and Mr. Kodaira have described some seiches that were observed in the lake of Asinokko in the northern part of the epicentral area shown in Fig 1 (*Japan J. Astr. Geoph.*, vol 9, p 115-125, 1932). The lake runs nearly north and south and is about 3½ miles long. The limnograph near the southern end of the lake was thrown out of action by the earthquake at 4.3 A.M., but at 7.20 A.M., when it was repaired, seiches of unusual size were recorded, the amplitude at 9 A.M. being 3.5 in. and the period 6.68 min., showing that the seiches were bimodal. On several other occasions, seiches were observed, usually on the days preceding swarms of earthquakes, for example, on Nov. 16, 19, and 20, when the numbers of fore-shocks on the following days were 64, 530, and 624, and on Dec. 1, 6, and 9, the numbers of after-shocks on the following days being 240, 286, and 592. The authors suggest that the seiches were caused by tiltings of the ground, which are known to precede the occurrence of earthquakes.

The tilting of the ground under different conditions is well illustrated in two recent papers (*Bull. Earthq. Res. Inst.*, vol 10, pp 130-144 and 145-170, 1932). In both cases, the instruments used were horizontal pendulums known as Ishimoto tiltmeters. Mr W. Inouye describes the movements at the observatory of Mt. Tukuba. The short-period fluctuations, as well as the daily and seasonal variations, are connected with changes in air temperature, an increase in which causes a decrease in the inclination of the mountain-side. Earthquakes generally occurred when irregular fluctuations of short period interrupted the long period variations or when the directions of the earth-tilts were changing. Observations of earth-tilts were made at Ito and Kawana in the Idu peninsula from March 19 until July 12, 1930, in connexion with the swarm of earthquakes at Ito during the spring of that year. Mr R. Takahashi shows that the tilts observed at Kawana must be attributed to changes in the tidal load, though there is some discordance, for which it is difficult to account, between the directions of the observed and calculated tilts.

### The British Iron and Steel Industry

AMONG the great industries of Britain which are suffering most from the abnormal conditions of trade is the iron and steel industry, regarding which, for various reasons, many erroneous views are held. The basic facts and circumstances of the industry are described by Prof. W. A. Bone in an article in *Chemistry and Industry* for April 8, entitled "A Survey of the British Iron and Steel Industry, 1913 to 1929 and 1930-31." Referring first to a misleading view expressed in an editorial in the *Observer* for Dec. 6 last, on the changes in the relative position of the iron industry in the United States, Germany, France, and Great Britain, and the effects of fiscal policy, Prof. Bone says, "The truth is that the changes so indicated have inevitably resulted from natural causes combined with human invention and post-War territorial changes, quite independently of any fiscal conditions, and that no change in our fiscal policy can or will prevent the natural course of events."

The supersession of puddled iron by Bessemer and open-hearth steel, the opening up of immense deposits of iron ore in America, the working of the 'basic' process in Germany, the retrocession of Lorraine to

France, and the comparative leanness of the iron ores of Britain are all factors which have led to other countries outstripping us as makers of iron and steel. Smelting and steel manufacture are, however, but two stages in the production of such things as railways, ships, bridges, and motor cars, and the really important question is: Which will pay us best to make, iron and steel or articles from partly imported materials?

Surveying the last nineteen years, Prof. Bone deals in turn with (1) production in 1913 and 1929, (2) a valuation of British iron and steel outputs in 1929, (3) imports of iron and steel raw materials and products in 1913 and 1929, (4) exports of iron and steel materials and products, (5) the slump since 1929, and concludes with some general considerations. In a series of valuable tables, he gives both the tonnage and the value of imports and exports, and from these it is seen that in 1913 the value of all the iron and steel products and manufactures exported from Great Britain was £111,775,000, the value of the corresponding imports was £36,175,000, leaving a balance in our favour of £75,600,000. The corresponding figures for

1929 were £160,930,000, £60,304,000, and £100,626,000. In 1929 the slump set in, affecting all the main iron and steel producing countries alike, and the world production of steel fell from 118,300,000 tons in 1929 to 93,330,000 in 1930 and 69,590,000 in 1931. In the United States, with its high tariff, the fall was no less than 54 per cent. At the conclusion of his survey, Prof Bone remarks that, "in view of the foregoing facts, which demonstrate beyond dispute not only how great has been the value of our vast export trade in iron and steel commodities within recent years, but also the ineffectiveness of tariffs to protect a country against the effects of a world-wide 'slump', the Government may well hesitate about adopting any measures calculated to raise steel prices to home consumers." "Some temporary measure of relief may be necessary to tide over the present emergency, but such measures should be safeguarded so that the dependent export industries shall not suffer through enhanced prices."

### The Plant in Relation to Water\*

THE study of plant life in arid regions has more than an academic interest. It throws important light on the relation of plants in general to their water supply. All things being equal, the plant is most valuable to man either as a crop or as forage when it gives the greatest yield with the least expenditure of water.

An arid region is not constantly hot and dry. It is one of extremes of climate. Plants growing there are not always faced with water shortage, at times they have enough and to spare. Nor are they always growing under a high temperature, extremes of cold have to be met as well as heat. The plants growing in dry regions are not of uniform type but very varied. A large proportion of the species are not drought resistant at all, and grow flowers during occasional dry spells, then die off. The succulent type, familiar through the cacti, with great stores of water which they expend very slowly, are peculiar and very rare in the natural flora of many dry countries. In Australia they are practically absent, and it is only a strictly limited area of light rainfall country that is threatened by the pest pear, not the great arid areas in South, Central, or Western Australia. The seriousness of the prickly pear is its menace to land that is good pastorally, not the danger to the more arid parts.

The various hard-leaved shrubs and trees of the dry country flora are plants of a type suited to climatic extremes. A curious feature of the Australian flora is that the shrubs and trees over most of the continent are of the hard-leaved type. This is the case even in the Sydney district, where the rainfall is good and the loss by evaporation annually is less than the rainfall. The hard-leaved structure does not mean that these plants are necessarily economical of water all the time, but that they can undergo more or less prolonged dry periods without injury.

In studying the drought resistance of various crop and fodder plants, some surprising results have emerged so far as the water requirements are concerned, thus, lucerne is about three times as lavish with its water as is sorghum in order to produce the same weight of dry material. The fact is that no single basis for drought resistance is known. The success or failure of a plant for economic purposes cannot be judged by its economical use of water alone. Even more important is its ability to remain active while water is running short and to survive dry spells.

\* From the presidential address to the Linnean Society of New South Wales delivered by Prof T G B Osborn on March 30.

### University and Educational Intelligence

CAMBRIDGE—Dr G P Bidder has given 5000 lire, with the promise of a like sum next January, for the benefit of the occupants of the Cambridge table at the Zoological Station at Naples.

Mr N F Mott, of Gonville and Caius College, has been appointed University lecturer in the Faculty of Mathematics.

The General Board has, on the recommendation of the Faculty Board of Mathematics, conferred the title of Stokes lecturer in mathematics on Dr P A M Dirac.

DUBLIN—Dr T J Nolan, State Chemist, Irish Free State, has been appointed professor of chemistry in University College, Dublin. Dr Nolan took over his new appointment on May 1.

MANCHESTER—The honorary degrees conferred at the commemoration of Founders' Day included the following—D Sc Sir James Jeans, LL D Lord Rutherford, Sir Arthur Salter, and Dr W D Ross.

OXFORD—The preamble of the statute establishing a final honour school of geography was moved in Congregation on May 10 by Mr C G T Morison, student of Christ Church, and carried without a division. Mr Morison laid stress on the necessity of an adequate scientific equipment for candidates in the school, with the view of providing which many different bodies have had to be consulted. The establishment of this examination will remove certain disadvantages under which graduates of Oxford have suffered in comparison with those of other universities.

THE Rockefeller Foundation, New York, U S A, has published the twentieth series of "Methods and Problems of Medical Education." It deals with many departments of study in medical schools in all parts of the world. The volume contains a number of admirable illustrations of the buildings and laboratories described, in many cases accompanied with plans to scale. The articles are not copyrighted, and may be reprinted or utilised in any manner without permission.

THE first award of the Swan Memorial Scholarship, established as a national memorial to Sir Joseph Wilson Swan, will be made this year by the council of the Institution of Electrical Engineers. The Swan Memorial Fund, the interest from which is devoted to the scholarship, was subscribed through the initiative of a committee composed of representatives of the County Borough of Sunderland, which was Swan's birthplace, and the Institution of Electrical Engineers. The scholarship has an approximate value of £140, and is tenable for one year. Candidates must be British subjects, less than twenty-seven years of age on July 1, and preference will be given to those associated with the County Borough of Sunderland. Awards of the following scholarships will also be made this year—Duddell Scholarship, annual value £150 for three years, age limit, nineteen years; Ferranti Scholarship, annual value £250 for two years, age limit, twenty-six years; Silvanus Thompson Scholarship, annual value £100 and tuition fees, age limit, twenty-two years, for two years, for works employees. Applications (specifically mentioning the name of the scholarship) for particulars of any of these scholarships should be addressed to the Secretary of the Institution, Savoy Place, London, W C 2.

## Calendar of Geographical Exploration

May 22, 1739 —The Ainu Race

Capt Spangberg left the harbour of Bolshaya Reka in Kamchatka on a journey to Japan. The Russian Government had sent him out in 1738 on one of the numerous northern expeditions organised about that time. Drift ice prevented anything but a survey of the Kurile Islands to lat  $46^{\circ}$  N in the first year. But after wintering in the above harbour, Spangberg with a companion vessel commanded by Walton, though separated by fog and storm, reached Japan. On the return journey Spangberg landed on an island north of Nippon in lat  $43^{\circ} 50'$ , where he saw the Ainu people, distinguished by their exceedingly abundant growth of hair. The Japanese and the Ainu everywhere received the Russians in a most friendly way. The Japanese archipelago, as surveyed by Spangberg and Walton, was so different from the maps then in use in St Petersburg that doubt was cast on their results and Spangberg was ordered to make a second voyage.

May 22, 1795 —Mungo Park on the Niger

Mungo Park, then twenty-four years old, left England for the first of his African voyages of exploration. He had previously sailed as a surgeon to Sumatra and had considerable botanical and zoological interests. On Dec 2, 1795, he set out on his journey to the interior, taking with him only a native and a slave boy. After a terrible journey, during which he was imprisoned and later suffered tortures from thirst and hunger, he succeeded in reaching Segu on the Niger and determining the eastward course of that river. On July 29, 1796, after following the Niger for eighty miles from Segu, he decided to leave the river and set out for the coast, a journey of 1900 miles, which he successfully accomplished, reaching the Gambia in May 1797. In January 1805, Park left England for the Gambia for the second time. He took with him a party of about forty Europeans, but most of them died before the Niger was sighted on Aug 18. Park sent back his journal, and set out to sail down the river on Nov 19. He and his party passed Timbuktu and reached the Bussa rapids in lat  $10^{\circ} 45' N$ , where the canoe stuck fast on a rock and the natives at the same time attacked the party from the shore, all were drowned. Though Park did not succeed in solving all the problems of the course of the Niger, he eliminated many of them.

May 23, 1875 —Inland Exploration of Australia

E. Giles began his journey from Port Augusta at the head of Spencer Gulf to Perth on the west coast of Australia, passing Lake Moore on his way. From Perth he went northwards to the upper Ashburton River and crossed Gibson's Desert from west to east. Giles had previously, in 1872, examined the upper course of the Finke River, penetrating into Gibson's Desert from the east. He was, however, compelled by adverse conditions to return without crossing it.

May 26, 1616 —William Baffin

Bylot and Baffin sailed on the most memorable of Baffin's many voyages. Baffin's Bay was discovered and explored, together with the magnificent series of straits which radiate from it, which were named Lancaster, Smith, and Jones Sounds, in honour of the patrons of his voyage. For 236 years, Baffin's farthest north, about  $77^{\circ} 45'$ , remained unsurpassed in that sea. Baffin is first mentioned as chief pilot on a voyage to search for the north-west passage in 1612. In 1615 he carefully examined Hudson Strait, the accuracy of

his soundings and observations being confirmed by Sir Edward Parry two centuries later (1821). In 1617-1619, Baffin surveyed parts of the Red Sea and the Persian Gulf, where he was killed in 1620. Baffin made numerous scientific, especially magnetic, observations. He was the first to determine longitude at sea by lunar observations.

May 27, 1926 —The Shaksgam Valley

Major Kenneth Mason reached Leh, whence he penetrated to the Shaksgam Valley, not visited by a European since Younghusband discovered it in 1889. Mason also explored the Aghil ranges and discovered the main features of the watershed between the Indian Ocean and Central Asia. His surveys altered the conception of the region and proved that the country beyond the Shaksgam River consists of a series of parallel ranges similar to those found on its Indian side.

May 28, 1789 —The Solomon Islands

Lieut. Shortland reached England after a voyage which added much to the map of Oceania. Shortland had accompanied the expedition of Capt Arthur Philip, sent out to found a penal settlement in Australia. On the return journey Shortland discovered "Sir C. Middleton's" Island, and on July 31 sighted San Cristobal, the most southerly of the Solomon group. He did not realise that the islands were separate, but thought that they were all one large island, to which he gave the name of New Georgia. He touched at Simba, and then went through the strait between Choiseul and Bougainville islands, sighting many small islands to the west, to which he gave the name of Treasury Islands. Alu, the largest of this group, is now generally known as Shortland.

## Societies and Academies

## LONDON

Physical Society, March 4 —L. G. Carpenter and T. F. Harle. A vacuum calorimeter for high temperatures. A form of the platinum-thermometer type of vacuum calorimeter has been developed which is suitable for the determination of true specific heats at high temperatures, since it is constructed without any organic insulating materials. The design is novel, in that the heat is transferred from the platinum coil to the calorimeter by radiation. —Hugh Carmichael. A new tilted electrometer. A new instrument on the principle of the Wilson tilted gold-leaf electrometer. It has a quartz fibre 'leaf' which moves in hydrogen to reduce sluggishness. Typical sensitivities of 3 mm. and 30 mm. fibre movement per volt (linear for 2 mm. and 1 mm. respectively) have been obtained, and a reliable eye-piece scale sensitivity of 1000 divisions per volt is within the range of the instrument. —N. W. McLachlan. The symmetrical modes of vibration of truncated conical shells with applications to loud-speaker diaphragms. With paper, glass, and aluminium shells, the modes crowd together as compared with the segregation which occurs in the case of a disc. With thick glass or aluminium of comparatively low loss, the nodal frequencies are very clearly defined peaks. In the case of paper cones driven by coils of small mass, the peaks disappear and the nodal region is indicated by a broad rounded contour. The influence of thickness, apical angle, and the mass of the driving coil are treated.

Society of Public Analysts, April 6 —K. Culhane and S. W. F. Underhill. The estimation of hormones. A description is given of the estimation of insulin,

pituitary posterior lobe extract, and adrenaline The effects of variations in the sensitiveness of the different animals is reduced to a minimum by using fairly large groups of a uniform stock —G Middleton The chemical assay of thyroid gland For the determination of the iodine content of thyroid gland a method is recommended in which the material is ignited with sodium carbonate in a double crucible —F W Jackson and Osman Jones The water-protein ratio of lean meat, and its bearing upon the analysis of sausages Data are given for the ratios of water to protein in samples of meat representative of the average quality used by the manufacturers of high-grade sausages By the use of these ratios the proportion of meat in sausages may be determined with a close approximation to the amount actually present —Osman Jones Nitrite in cured meats Nitrite-cured meats may contain 960 parts nitrite per million when brine has been repeatedly used for curing The only function of the nitrate is to impart a red colour to the meat by reduction to nitrite It would be advantageous to replace nitrates in curing by a very small amount of nitrite —H C Lockwood Notes on the freezing point of milk An apparatus and method for the determination of the freezing point of milk are described

Optical Society, April 14 —F Twyman A photometric eyepiece for visual quantitative spectrum analysis A new type of eyepiece is described whereby a spectrum is split into halves, a selected line of one spectrum being brought vertically above a selected line of the other spectrum The intensity of the brighter line is then reduced by means of a neutral tint wedge until equality of the two intensities is obtained The eyepiece is used in an analysis of some cadmium-lead alloys, an accuracy of some 11 per cent of the content being obtained —T Smith and J Guild The CIE colorimetric standards and their use The new international standards, which define a standard observer, three standard illuminants, standard conditions of illuminating and viewing opaque specimens, a standard for evaluating the brightness factor of opaque specimens, and a standard trichromatic system for the expression of colour measurements, are stated and their origin explained In addition to the numerical tables which are appended to the resolutions setting up these standards, there are given a table specifying the trichromatic co-ordinates for the standard observer of all spectral colours at wave-length intervals of 1 mμ, tables to facilitate the calculation of the standard co-ordinates and the brightness factor of a material illuminated by any one of the three standard illuminants from spectrophotometric measurements on the material, and a table giving the co-ordinates of some stimuli of special importance on the N P L system, the standard system, and another system which occurs in the resolutions

Bailly A new enzootic disease of the rabbit suppurating otitis of the middle ear

## GENEVA

Society of Physics and Natural History, Feb. 18.—Fernand Chodat and Jean Landis Studies on the nutrition of the yeasts The authors present a study of the nutrition of the yeast fungi, capable of transforming under economic conditions inorganic nitrogen into peptide nitrogen *Endomyces anomalus*, which fulfils these requirements in a satisfactory manner, is studied from the points of view of its growth and autolysis.—Léon W. Collett and Ed. Parejas Results of the geological expedition of Harvard University in the Canadian Rockies (Jasper National Park), 1929 (6) Geological section along the Rockies, the Athabasca length The section surveyed by the authors extends over a distance of 50 km from the eastern edge of the Rockies to the river Miette, an affluent of the Athabasca It comprises seven distinct strata

March 3.—A. Borloz The pickling of copper-silver alloys in dilute sulphuric acid Experience in the cleaning of these 82.5 per cent alloys shows that the operation is more successful when copper sulphate is added In seeking for a theoretical explanation of this action, the author thinks that the copper cation acts as a surface catalyst, experiment having proved that electro-osmosis cannot be the cause.—Leon W. Collett and Ed. Parejas Results of the geological expedition of Harvard University in the Canadian Rockies (Jasper National Park), 1929 (7) The geology of Mount Edith Cavell The authors describe in detail some phenomena of detachment which are produced at Mount Edith Cavell and in the Tonquin Valley between an enormous mass of Cambrian quartzites and Pre-Cambrian clay schists.—(8) The broken strata of Moose Pass Are the overlappings of Moose Pass and Pyramid equivalent? This is the problem of tectonics set by the authors

March 17.—Th. Posternak The configuration of quercite By controlled oxidation with alkaline permanganate, the author has obtained a substance identical with Kihani's metasaccharonic acid From this a configuration is deduced which completely explains all its properties.—W. H. Schopfer The accessory growth factor of the micro-organism contained in the wheat germ its action on the sexuality of the *Phycomyces* The author's experiments make clear the existence in the wheat germ of a growth and sexuality factor the vitamin value of which is certain.—J. and L. Deshusses An anguillulosis of *hortensia* (*Hydrangea hortensis*) The authors have studied the ravages caused by *Tylenchus dipsaci*, more especially in certain varieties of *hortensia*, amongst others *Maréchal Foch* and *Niedersachsen* The *Goliath* and *De Vibraye* varieties are less attacked The authors make suggestions for fighting this parasite.

## PRAGUE

Czech Academy of Sciences and Arts, Oct. 16.—Boh. Němec Mixoploidy in *Allium caeruleum* Pal.—V. Posejpal Fourth contribution to the study of universal ether A formula for the intensities of the

K-absorption edge is deduced on the assumption that the cross-section of a photon has the same area as that of an ether particle.—B. Nováková The determination of differences of wave-lengths in spectra of the central region and limb of the sun measured by spectrocomparator and microphotometer.—F. Valentin A study in the series of alcoholic sugars Alcoholic sugars were converted by means of triphenylchloromethane into triphenyl-methylethers, and interesting regularities were found in the number of triphenylmethyl groups entering a molecule

Nov. 13.—J. H. Křepelka and B. Rejha The anhydride and hydrates of manganese sulphate Six forms of manganous sulphate were found, namely, anhydrous, simple, and bimeric monohydrate, tetra-, penta-, hepta-hydrate, other forms mentioned in literature, such as the hemi-, di-, tri-hydrate, second form of tetra-hydrate, and hexahydrate, do not appear to exist The melting points and ranges of existence are given.—O. Pankraz On the divergence of the Dirichlet integral

Dec. 11.—V. Posejpal Fifth contribution to the study of the universal ether From the conception of ether drift and on the assumption that the volume of ether carried away by molecules of water vapour equals that of water molecules calculated from viscosity, the author derives from the refractivity of water, vapour-radius  $\alpha$ , these denote the sphere of ether inside water molecules, which is impenetrable for photons,  $\alpha$  being given by  $\alpha + \beta\lambda$ .—F. Ulrich and J. Sandholzer Radioactivity of wells in the Riesengebirge in Bohemia.—M. Mikan (1) An example of Cremona correspondence in penta-dimensional space (2) Plane presentation of penta-dimensional forms.—J. Chloupek and V. Daneš Solubilities and activity coefficients of silver sulphate in certain salt solutions Exact solubility determinations were made in water and aqueous solutions of  $K_2SO_4$ ,  $(NH_4)_2SO_4$ ,  $KNO_3$  from 0.08 to 2N at 25° C, hence activity coefficients were calculated.—V. Prelog, G. Držić, and V. Hanousek On the bis- $\beta$ -halogenethylamines These compounds were obtained from bis- $\beta$ -hydroxyethyl-amines by means of halogen acids, they yield with potassium cyanide 2-imino-3- $\beta$ -halogenethyl-oxazolidines, and with potassium thiocyanate the free bases 2-imino-3- $\beta$ -halogenethylthiazolidines

## Forthcoming Events

## FRIDAY, MAY 20

ROYAL SOCIETY OF MEDICINE (Physical Medicine Section), at 5.30.—Annual General Meeting  
ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynaecology Section), at 8.15.—Annual General Meeting  
ROYAL SOCIETY OF MEDICINE (Radiology Section), at 8.30.—Annual General Meeting  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. H. E. Armstrong Faraday at the Sign of the Hexagon Coal Colour and Constitution  
INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Sedbury, Monmouthshire)—Summer Meeting (continued on May 21 to 23)

## SATURDAY, MAY 21

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.—Annual General Meeting  
GERMAN CONGRESS FOR PSYCHICAL HYGIENE (at Bonn)

## MONDAY, MAY 23

VOLUNTARY EUGENIC STERILISATION (Conference at Caxton Hall, Westminster), 10.30 a.m. to 12.30.—Medical and Legal Aspects of Sterilisation, Sterilisation in Other Countries.—2.30 to 4.30.—Social and Moral Aspects of Sterilisation, Practical Proposals.—8.30.—Informal Discussion

- MIDDLESEX HOSPITAL MEDICAL SCHOOL, at 5—Prof Samson Wright Certain Aspects of the Reflex Control of the Circulation (Succeeding Lectures on May 26 and 30, June 2, 6, and 9)
- ROYAL SOCIETY OF ARTS, at 5 15—Sir Ernest Graham Little Dermatology as an Outpost of Medicine (Malcolm Morris Memorial Lecture)
- IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, at 5 30—Prof F Silvestri The Biological Control of Insects and Weed Pests (1) (Succeeding Lectures on May 25 and 27)
- UNIVERSITY COLLEGE, at 5 30—Prof A. M. Tallgren Central Asiatic and Siberian Rock-Pictures (1) (Succeeding Lecture on May 25)
- IRON AND STEEL INSTITUTE (Additional Meeting) (jointly with Cleveland Institution of Engineers) (at Cleveland Technical Institute), at 7 30—Presentation of Papers
- ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8—Annual General Meeting

## TUESDAY, MAY 24

- ROYAL SCHOOL OF MINES (in Geological Lecture Theatre), at 12 noon—Dr H. Shaw Field Practice with the Torsion Balance (1) (Succeeding Lectures on May 27 and 31)
- IRON AND STEEL INSTITUTE (Additional Meeting) (jointly with Sheffield Metallurgical Association) (in Mappin Hall, Sheffield University), at 2 45—Presentation of Papers
- ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5—Annual General Meeting
- ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section), at 5—Discussion on Some Problems concerning the Prevention and Treatment of Acute Rheumatic Infection
- ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30—Rev T. Cullen Young Tribal Intermixture in Northern Nyasaland (Lecture)

## WEDNESDAY, MAY 25

- BRITISH SCIENCE GUILD (Annual General Meeting) (at Royal Society of Arts), at 4—At 5—Prof S. Chapman Polar Lights (Lecture)
- SCHOOL OF ORIENTAL STUDIES, at 5 30—Dr M. de Z. Wickremasinghe The Home of Pali, the Sacred Language of the Southern Buddhists (Lecture)
- INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6—Prof E. V. Appleton Our Present Knowledge of the Ionised Regions of the Upper Atmosphere (Lecture)
- BRITISH INSTITUTE OF PHILOSOPHY (at University College), at 8 30—Sir Herbert Samuel Philosophy and the Ordinary Man (Presidential Address)

## THURSDAY, MAY 26

- ROYAL SOCIETY OF MEDICINE (Urology Section), at 8 30—Annual General Meeting
- ROYAL AERONAUTICAL SOCIETY (in Science Museum, Aeronautical Section), at 9 15—H. E. Wimperis New Methods of Research in Aeronautics (Wilbur Wright Memorial Lecture)

## FRIDAY, MAY 27

- LONDON SCHOOL OF ECONOMICS, at 5—Prof L. Hogben The Biological Premises of Historical Interpretation (Lecture)
- ROYAL ANTHROPOLOGICAL INSTITUTE (Human Biology Research Committee), at 5 30—Discussion on the Standardisation of Anthropometric Method
- BIRKBECK COLLEGE, at 6—Dr H. J. W. Hetherington Theory and Practice (Haldane Memorial Lecture)
- ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8—Annual General Meeting
- ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir Walter Morley Fletcher New Conceptions of Medical Research

## SATURDAY, MAY 28

- NORMAN LOCKYER OBSERVATORY (Salcombe Regis, Sidmouth), at 3 30—Opening by Sir Frank Dyson of the 'Mond' Photographic Equatorial and Dome Other speakers: Sir Richard Gregory, Bart, Dr R. L. Mond, and others
- ROYAL SOCIETY OF MEDICINE (Physical Medicine Section)—Annual Summer Meeting (at Alton)

## Official Publications Received

## University Science Teaching

CONSIDERABLE attention has recently been devoted in the columns of NATURE and elsewhere to emphasising the importance to civilisation of the application of the type of thinking used in scientific research to the present difficult and widespread political, economic, and social problems. By an extensive application of the natural knowledge contained in the sciences of mathematics, physics, and chemistry, much progress has been made in satisfactorily feeding, clothing, cleansing, and housing humanity. Successful civilisation, however, involves much more than the satisfying of the most elementary bodily needs. Until the biological and mental sciences are much more advanced, science cannot supply the facts of these other needs.

As a result of this one-sided application of scientific knowledge, present civilisation is in danger of collapse. The recent official surrender of party politics in Britain, involving as it does much individual loss of personal advantages, may be interpreted as evidence that the politicians themselves have less faith than formerly in the power of their methods to deal with political problems. Since the application of the scientific spirit is the only seriously suggested method which has not been tried, it is worth while considering what practical steps should first be taken. These are generally believed to be certain changes in the nature and extent of science teaching, where the word science is used in its widest sense to cover both scientific knowledge about organic and inorganic objects and also scientific method, that is, the type of thinking by which the knowledge was established. It is assumed that the products of such education will then naturally use the type of thinking used in establishing scientific knowledge.

The fundamental difficulty lies in the striking fact that amongst research workers, who by the soundness of their work clearly prove that they are capable of applying, and in fact regularly do apply, scientific thinking in the laboratory, some do and some do not spontaneously apply the same type of thinking to problems outside the laboratory. This statement needs careful consideration, for it is almost impossible to give here supporting evidence. If, however, observation be confined to private conversation between intimate friends, it will be apparent that the regular and spontaneous application of scientific thought in the laboratory may or may not be accompanied by a spontaneous application of the same type of thinking

to affairs outside the laboratory. Undoubtedly, some research workers can and do detach and leave behind in the laboratory both the scientific way of thinking and the laboratory dust-coat, alike with equal ease and naturalness. If these men who regularly apply scientific method to one subject do not spontaneously apply it to other subjects, how can one reasonably expect, for example, the politician, who may well have had no scientific training whatever, to apply scientific thinking in dealing with political problems?

We would emphasise here that no known method could, on the basis of experimental evidence, be guaranteed to overcome this difficulty. Even intimate familiarity with a science does not compel the use of scientific thinking in that science or in other topics, but it must be remembered that no serious and widespread attempt has been made to teach scientific method. Evidence of such teaching may be sought in vain in the widely used textbooks of any of the sciences or in the examination papers of the universities. Since the present type of science teaching does not produce a scientific habit of mind, the only untried method which suggests itself as a possible means to such an end is the teaching of scientific method in addition to the teaching of the sciences. Although we would again emphasise that there is no adequate evidence to show that such teaching would produce the desired result, it must be realised that until the method has been actually tried such evidence could not exist. Since we believe that the method should be tried, we will tentatively offer various considerations as to the best means.

We must be quite clear as to what is proposed to be taught. Scientific method has nothing to do with the origin of new ideas spontaneously arising in the brain of an individual by a process known to no man. It is concerned solely with the way those ideas have to be developed to *establish* a new piece of knowledge. Scientific method can be reduced to comparatively few principles, the application and misapplication of which can be well illustrated even in the most elementary science teaching. The principles would be best absorbed by constant reference to them in the ordinary lecture and laboratory instruction rather than by an attempt to teach them in a separate course. Where this plan of constantly associating principles with facts is adopted throughout the school and university course, the actual time devoted to instruction in scientific method would not amount at most to more than a few minutes in each hour of teaching.

A science such as physics, combining as it does both mathematics and experiment, is especially well adapted to the teaching of scientific method, and great care would have to be taken that the elementary courses in physics and in chemistry were carefully planned so that students who later specialised in biological sciences would have obtained a good idea of the principles of scientific method from their elementary course in physics and chemistry, where the phenomena are of comparative simplicity. Instruction in scientific method would of course be continued in combination with the advanced biological training, but since biological science cannot deal with standard normal objects, the statistical complications make it less suitable as a medium for a first initiation into scientific method.

Although this teaching of scientific method should ultimately be carried out in both school and university, it will naturally have to start in the universities where science masters receive their more specialised training. Here will arise the difficulty of a dearth of teachers. Since the standard textbooks of all the sciences give only the facts and principles of the sciences, and pay no attention to the kind of thinking by which the facts are established, the new science teaching will have to be created separately by each of its supporters.

University teachers are, however, of three types. First there is the research worker, for whom a university is essentially the only place where research work may be carried out without any thought of its industrial application, and where the teaching duties must be merely tolerated. For the second type, a university differs essentially from a school only in that the students are older pupils who have to be spoon-fed for fewer teaching hours with fewer but more difficult subjects than at school. This type usually does no research whatever. In the lecture room, his courses admirably cover the field on which the student will later be examined. In the laboratory, no sooner is a student in difficulty than the demonstrator is by his side, ensuring no 'waste' of the student's time, by at once pointing out the errors. This type would, by his professor, be described as a good teacher—the adjective being used, dare we venture to suggest, as a reward for the *smooth* running of teaching laboratories. From neither of these types would one naturally expect the new teaching. The most likely source is the third type, who at heart believes and practises that research and teaching are equally prime functions of a university. As there would be a danger of this type being sadly

overworked, we will consider how far *extensive* lecture and laboratory courses are nowadays necessary in teaching science subjects in universities

Apart from tradition, only three reasons for lecture courses need be considered. First, since science deals with Nature rather than with books, the actual objects and phenomena of a science must, wherever possible, be seen or experienced by the student. This justifies the lecture illustrated by experimental and other means. Secondly, lectures which, although not illustrated by experiment, deal with advances so recent that they do not appear in the textbooks, are necessarily a part of all honours degree courses. The third reason often given for extensive tuition in universities needs more careful examination. It is frequently stated in discussions that in the provincial universities many of the students cannot absorb knowledge from even the best written textbooks. If it can be established that some students worthy of university education cannot be *trained* in the upper forms of schools and in the universities to assimilate ideas and knowledge from the symbols of a printed page, then surely gramophone records, sound-films, and 'readers' who would read aloud from good textbooks should all be used for this type of student. Their possible existence in universities is no justification for extensive spoon-feeding courses of lectures.

As to laboratory instruction, all science students, no matter how brilliant, must spend time in the laboratory in familiarising themselves with the main objects and phenomena of their particular science and in acquiring its manipulative technique. Such essential laboratory courses would serve admirably for illustrating practical application of scientific method. It is highly controversial whether the more extensive laboratory courses designed to help weak students to acquire knowledge are in reality justifiable, and it is very doubtful if they should be regarded as essential for all students. They offer little scope for developing the student's powers of imagination, they leave him little time for independent reading, they hinder the combined study of two sciences, such as, say, geology and physics, they prevent the combined study of three sciences, such as physiology, physics, and chemistry, and finally, they absorb time of demonstrators which should be devoted to research. Whilst spoon-feeding of some ordinary degree students may by some be regarded as desirable, there can surely be no justification for the spoon-feeding of honours degree students. The wisdom

of the policy of helping normal students to get honours degrees so that they will receive higher salaries in schools adopting the Burnham Scale is extremely doubtful, since it favours the present highly specialised school science teaching with its shocking neglect of biological science, a course which is itself of doubtful value even for the one student out of every thousand who may ultimately become a specialist research worker.

As we see it, then, present needs would best be served if extensive spoon-feeding lecture and laboratory courses were abolished in universities, and if into all science teaching instruction in scientific method were incorporated. When good means of accomplishing this have been developed by actual trial, all the textbooks intended for undergraduates should be rewritten so as to include always some discussion of the means by which the facts and principles of the knowledge are established. This type of science teaching should then spread to the schools, where, as a means of discouraging early specialisation, higher salaries should not necessarily be paid to masters with honours degrees. Extensive science teaching of even the best present type—that which includes biological science—can always be justified on the ground that it teaches the nature of the environment in which human life must be spent. It is too much to hope that the new science teaching would in addition tend to induce a scientific habit of mind, but if it could induce, for example, an appreciation of the differences between fact and opinion, it would be well worth while.

### Form and Size

*Problems of Relative Growth* By Julian S Huxley  
Pp xix + 276 (London Methuen and Co, Ltd,  
1932) 12s 6d net

**D**URING the greater part of his life, man changes but little in form. In this important character he differs greatly from the majority of living organisms. By reference to ourselves, the concept of the form of an organism appears well defined, but this is to a large extent the result of our own constancy. In most organisms, our task is not that of describing a single well-defined structure, but the description of a sequence of continuously changing structures.

The study of these structural changes is of great importance. Any empirical rules which can be found to bring order into the embarrassing array of facts and observations are most valuable, for it is only with the aid of such rules that we can perceive the nature of the problems which require solution.

Huxley has succeeded admirably in bringing about such a co-ordination of data in his latest book. He has shown that certain comparatively simple relations between the sizes of various parts of the organism hold over a very wide range of cases and throw light on many obscure facts.

When an organism increases in size, its organs and limbs do not necessarily—nor, indeed, usually—increase at the same rate as the whole organism. Some structures develop at a much faster rate than the organism as a whole. Such 'heterogonic' growth leads to progressive change in the form of the organism, so that in large individuals the relative proportions of their parts may differ greatly from those of small ones. Huxley has shown that such facts may be expressed quantitatively by an empirical formula. If  $y$  represents the magnitude of an organ and  $x$  represents that of the rest of the organism, then the relation,  $y = bx^k$ , expresses the magnitude of the organ for any given size of the organism,  $b$  and  $k$  are constants,  $k$  representing the relative rate of increase of  $y$  with respect to  $x$ . If  $k = 1$ ,  $x$  and  $y$  increase together at the same rate, and the form of the animal remains unchanged as it increases in size, that is, growth is isogonic. But if  $k > 1$ , the organ increases more rapidly than the rest of the body, and the form of the organism undergoes continuous heterogonic change.

The formula is necessarily empirical. Of the causes of differential growth we have little knowledge, their investigation is the problem at issue. A variety of possible relations might, in fact, reduce approximately to this formula. But it is not the object of the formula to establish the correctness of a particular hypothesis as to the cause of differential growth, it merely expresses the observed facts with considerable accuracy in a simple way, so that many very significant features emerge which would not otherwise do so.

The formula clearly lends itself to graphic expression, and it is found, by plotting a large number of observations, that the value of  $k$  remains constant over a wide range of size. The large chela of the fiddler crab, *Uca pugnax*, increases in size about sixty per cent more rapidly than the rest of the body, so that though the chela is initially of normal proportions in the smallest individuals, it may approach seventy per cent of the weight of the rest of the body in the largest. Despite this gross change in form, the constant value of  $k$  shows that the relative growth rate of the chela has remained unchanged. The growth rates are thus a more constant feature of the organism than the morphological structure at any stage.

The substantiation of such an empirical relation necessitates its application in a very large number of instances, and the author has taken pains to establish it over a wide selection of organisms, ranging from plants to mammals.

It is important to realise that the relation compares the relative size of parts with increasing size of the organism. It makes no implication as to the actual rate of growth. Such increase in size is certainly brought about by growth—in which time governs the degree of multiplication undergone by the living substance. But Huxley points out that it is not necessarily the rate of growth which is regulated in accordance with the formula. The antlers of deer follow the heterogonic relation, but these are shed each year, so that their size in relation to body-weight cannot be the accumulated result of continuous growth at a rate different from that of the body. In fact, the relation is not the simple consequence of rate of growth at all, but expresses some natural limitation of the extent to which an organ can grow with respect to the size of the rest of the animal. The discontinuous growth of arthropods yields similar evidence. But the most convincing evidence that the relation concerns size limitation rather than growth rate comes from observations that regenerating organs grow at a highly accelerated pace until they reach the appropriate size corresponding to the formula, after which the rate drops to a value consonant with the normal. The evidence of transplantation of organs suggests that this limitation of size is controlled in part by mechanisms specific for each organ.

The conclusion that in Huxley's formula we are dealing with conditions of size limitation rather than rate of growth is very important, and illustrates how productive may be this method of approaching the problem.

The principle of heterogonic growth greatly simplifies a large number of problems concerning form. Polymorphism and dimorphism in insects can be shown in some cases to be the direct consequence of heterogonic increase in particular organs with increase in size. Nor is the principle limited to particular species, homologous organs tend to undergo heterogonic increase with increasing size among related species. The significance of this is far-reaching, and may well open to experimental attack the peculiar limitations in the evolution of organ-form associated with orthogenesis.

Heterogonic growth is not a localised condition in one particular organ. It is the result of a growth gradient which, while it may reach its maximal expression in a particular organ, in fact pervades the

whole organism. The form of the organism may, indeed, be interpreted by means of a system of such growth gradients. The expression of the size relations of organs in terms of heterogonic growth thus becomes a special application of the rules governing form which were first put forward by D'Arcy Thompson, to whom the author expresses his debt.

Of the origin and nature of the growth gradients we have at present little knowledge. But the influence of hormones on the relative growth of the parts of animals suggests that the control of size may in part be under such chemical influences.

Perhaps the outstanding conclusion of the whole book is the importance of size regulation independently of rate of growth. It is possibly a pity that the attempt to relate heterogonic size change and growth rate should be made at the beginning of the book rather than at the end. The heterogonic formula which the author has emphasised is an empirical one. It does not rest upon preconceived hypotheses as to the nature and rate of growth processes. For such an empirical relation no apology whatever is required, for its usefulness is fully demonstrated throughout the book. The importance of the relation of heterogonic size change to rate of growth is abundantly clear, but the book leads us up to this problem rather than employs it as the basis upon which the work has been executed. But this is a matter of opinion. In any event, it cannot obscure the essential fertility of the method for the presentation of problems in a form suitable for experimental solution.

The book is well and profusely illustrated. It is a book which every biological library should possess and every student of biology can read with profit.

C. F. A. PANTIN

### Modern Theoretical Physics

*Theoretical Physics* By Prof W Wilson Vol 1  
*Mechanics and Heat, Newton-Carnot* Pp x + 332 (London Methuen and Co, Ltd, 1931)  
21s net

THE difficulty of presenting to students an account of the theoretical side of physics which will be adequate without being so voluminous as to encroach unfairly on the time available for other aspects of the subject, is one which to-day must cause much anxious thought to university teachers. It is not merely a question of the increasing amount of material to be handled. The changes which have taken place in fundamental principles, the transitional character of some of

the hypotheses which have helped to support the structure in this period of change, and the tendency to abandon the physical model in favour of the mathematical equation as a basis for 'explanation', combine to make it an almost impossible task for the teacher to guide the studies of his pupils so wisely that nothing of importance for exhibiting the unity of physical theory shall be omitted and, at the same time, sufficient time shall be allowed for proper assimilation of principle and application even on the part of the brightest honours man.

In this embarrassing situation, every teacher and student should welcome the work of Prof Wilson, of which the first volume is before us. This volume is entirely classical in character, and its contents can be roughly grouped under three headings, mechanical, statistical, and thermodynamical. In view of the fact that no one can fully appreciate the changes wrought in physical theory by the quantum hypothesis without a real grasp of general dynamical methods, the author is to be commended for having devoted a considerable portion of the volume (nearly one-third) to an admirable account of dynamical theory embodying a well-chosen body of special applications, many of which will be required later for the purposes of atomic models, and leading to an exposition of Hamilton's equations and the principle of stationary action. There is a chapter on the general equations of wave propagation, and one on the analysis of stress and strain in elastic media, two further chapters on the dynamics of perfect and viscous fluids complete the part of the volume devoted to purely mechanical considerations.

The material chosen for this part has been wisely selected, and the method of treatment is careful, detailed, and free from the 'scrappiness' which characterises many expositions of this most important branch of physical science. The methods of statistical mechanics are outlined in a chapter which might well have been longer, in view of the highly abstract nature of the Gibbs ensemble, which would well merit a few more pages of explanation. Three chapters are devoted to the laws of thermodynamics and applications of them to homogeneous and heterogeneous systems, the Kelvin scale of temperature, latent heats, the phase rule, and dilute solutions. There is also a chapter on the kinetic theory of gases.

The one disappointing feature of the book is the failure to utilise vector and tensor methods in a more thorough fashion. To be sure, the author gives an exposition of vector and tensor analysis at the outset and promises a more complete

discussion in a later volume, but it seems to the reviewer that had a fuller account of these matters been provided here, much space would have been saved in this volume by the abandonment of clumsy Cartesian expressions in favour of the elegant and concise vector equations, not to mention the fact that the volume would have been imbued much more with the real spirit of the vector calculus. There is a danger that the reader may regard vector symbolism as merely a convenient 'shorthand' for Cartesian equations and expressions.

The author's use of clarendon type does not appear to be consistent. It is generally understood that such type is used only for vector quantities, whereas in this book it is at times employed to represent scalar quantities as well. However, in all other respects the work has been admirably done, both in the range of topics which have been dealt with and the completeness of the analytical methods employed. The book can be heartily recommended to student and teacher alike, and it is to be hoped that the two subsequent volumes, which are to deal with electromagnetism, optics, relativity, and quantum mechanics, will not be long delayed.

### Snow and Ice Crystals

*Snow Crystals* By W A Bentley and W J Humphreys Pp ix + 22 + 204 plates (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1931) 60s net

MR W A BENTLEY, whose death on Dec 23, 1931, at the age of sixty-six years we regret to record, was known for many years as a patient and skilful artist and photographer of snow and ice crystals, Mr W J Humphreys as a no less skilful physicist and meteorologist. Between them, they have produced a most unusual and very readable book. Incidentally, Mr Humphreys has also revealed himself on the last page of this publication as a poet of no small merit.

The publication of the book is due to the generosity of an anonymous donor to the American Meteorological Society. The book consists of 227 pages, of which all but twenty-two are reproductions of photographs taken during many years by Mr Bentley. More than two thousand photomicrographs are reproduced, the majority of which are of varieties of snowflakes. Other forms of snow crystal are, however, represented, together with examples of ice flowers, window-pane frost,

dew, rime, and other types of ice formation. These reproductions will appeal to any artist, but the diversity of form of the crystals is at first somewhat bewildering. This is due partly to the variety of shape of the crystals, but even more to the varied structure of the flakes due to the inclusions of air or water, variations in thickness, and surface water films resulting from slight melting. These differences in structure depend on the conditions in which the snowflakes were formed, and it should be possible, therefore, to gain some insight into the conditions associated with the formation of a definite type, when sufficient further data become available. Unfortunately, the places of origin and the paths pursued by the flakes falling at any instant at one spot may vary, and some information regarding the diversity of form amongst a number of flakes collected simultaneously would have been welcome.

Evidently it is not easy to deduce cause from effect in such a complicated subject, and it is apparently not possible to amplify Bentley's statement in the *Monthly Weather Review* of May 1901, regarding the relative abundance of crystals of simple and complex shapes in the opposite sectors of general snowstorms in the United States. The general rule is that the simpler kinds—columns, needles, and plates—are formed at greater altitudes and in lower temperatures, and are associated with relatively slow growth. They are thus most commonly found in high latitudes, and this accounts for the statement, no doubt true for the New England States, that perhaps three-fourths of all snow crystals belong to the 'tabular' type. Brief reference is made to the types of snow crystal which cause haloes.

In some respects, the most interesting of the photographs are those of window-pane frost, the forms of which are doubtless sometimes associated with the structure of the glass surface. Why, however, these should sometimes take the form of graceful plumes, why sometimes possess a granular structure, and why, at other times, form a 'fir-tree' or 'herring-bone' pattern, is extremely puzzling, and the explanation must be associated with the availability of moisture, the rate of formation, and possibly the form (vapour or liquid) in which the moisture is present.

More information regarding the very interesting ice flowers shown on p 221 would have been welcome. The photographs show round discs of ice which have formed in water. These later develop scallops on their circumference, which then grow more quickly in six favoured equidistant

places, and finally develop into a crystal form reminiscent of certain snowflakes. One of these photographs shows how crowding has impaired the symmetrical growth. Other examples of equal interest were illustrated in the *Monthly Weather Review* for November 1907.

It is hoped that the publication of this volume will stimulate interest in a study which is not only fascinating, but also requires little apparatus, though much patience and skill, for its prosecution.

### The Evolution of Culture

*The Evolution of Culture* By Julius Lippert  
Translated and edited by Prof. George Peter Murdock. Pp. xxxiii + 716. (London: George Allen and Unwin, Ltd., 1931.) 20s. net.

PROF. MURDOCK, of Yale University, has made an admirable translation of Lippert's "Kulturgeschichte der Menschheit in ihrem organischen Aufbau" (1886-87), which together with his other writings, gained for the author the reputation in Germany of being in the front rank of sociologists, though his work has scarcely had due recognition in other countries. At that time trustworthy data on the ethnography of backward peoples were very scanty and incomplete, so it is not surprising that occasionally his imagination led him beyond his facts and that he was inclined to read too much into them. Such faults are characteristic of most pioneers, but Lippert consciously strove to be inductive, as is shown by his use of the method of comparative ethnology. His approach was distinctly evolutionary, as was almost inevitable at that time, and he covered, so far as he could, the whole field of social anthropology with a due regard to balance and perspective. He did not, however, make the common mistake of confusing evolution with progress. Although Lippert says that "human ingenuity has striven in different places to achieve the goal set by the care for life with the elements there at hand" (p. 169), he does not ignore diffusion from a single centre in the case of the bow (p. 180) and claims it for the fire cult (p. 584) and for the origin of grape wine (p. 199), but in his time the conception of the diffusion of cultures had not achieved the importance which it has now attained.

Although, according to Lippert, social evolution finds expression in increasing foresight and socialisation, and although he regards economic factors as playing an important part in that evolution, he recognises that it is "characteristic of the evolution of mankind that on each stage it has

been stimulated and directed by a subjective element, its store of ideas. Undoubtedly man has gone astray on devious paths in his interpretation of objective reality on these devious paths of trial and error man has created, or rather acquired incidentally, a series of means adopted to bring about social integration and an extension of foresight" (p. 345).

The editor has wisely used his discretion in translation, his object was to do full justice to the meaning rather than to the wording of the original text, and thus we are indebted to him for a clearly expressed rendering of a very ponderous and involved argument. The original was devoid of references, but wherever possible the editor has recovered these and has added very numerous references to more recent literature which largely make up for the out-of-date information of the author. Lippert himself was strongest on the history and literature of classical antiquity and on the folklore and history of the Germanic and Slavic peoples, and he was fairly well acquainted with the then available ethnographic evidence. He is eminently suggestive, and students of sociology will find much that will throw light on problems in which they are interested.

A. C. HADDON

### Short Reviews

*Annual Reports on the Progress of Chemistry for 1931*. Issued by the Chemical Society. Vol. 28. Pp. 443. (London: Chemical Society, 1932.) 10s. 6d. net.

THE divisions of chemistry which receive annual treatment in the Chemical Society's report—general and physical chemistry (C. N. Hinshelwood), inorganic chemistry (H. Bassett), organic chemistry (aliphatic: E. H. Farmer, homocyclic: G. M. Bennett and J. W. Baker, heterocyclic: S. G. P. Plant), analytical chemistry (J. J. Fox and B. A. Ellis), and biochemistry (A. G. Pollard and J. Pryde)—are on this occasion joined by crystallography (J. D. Bernal and W. A. Wooster), colloid chemistry (W. T. Astbury, D. C. Henry, E. K. Rideal, and R. K. Schofield), and the structure of simple molecules (N. V. Sidgwick and E. J. Bowen). The sound policy of not attempting the impossible is continued, and the report therefore is to be regarded as a collection of short reviews on selected subjects rather than as a compressed record.

Among the subjects treated by Mr. Hinshelwood are effects attributed to the intensive drying of liquids, adsorption at surfaces, and chemical kinetics. Prof. Bassett refers cautiously to the announcement of the discovery of the missing alkali metal (No. 87), Dr. Farmer commences his section with a discussion of olefinic and polyolefinic additions, Prof. Bennett and Dr. Baker continue

the study of prototropy which was dealt with in the 1929 report, that of aromatic substitution from 1930, and that of the bile acids from 1928. Dr Plant's chapter refers to oxygen ring compounds, five-membered nitrogen ring compounds, and alkaloids. The report on analytical chemistry includes a discussion of the sensitiveness of precipitation reactions, and refers to the analytical use of arc and spark spectra.

Biochemistry was enriched during the period under review by important new knowledge concerning the fat-soluble vitamins. The report on crystallography covers the progress of two years, and is divided into crystal physics and crystal chemistry. The report on colloid chemistry is confined to three important topics: the structure of fibres (Dr Astbury), electrokinetic phenomena (Mr Henry), and the colloid chemistry of clays (Dr Schofield), that on the structure of simple molecules to the distances between the linked atoms, the force constants of the links, the mean restoring forces during vibration, the energy involved when the atoms form the link, the angles between the valencies, and the dipole moments of the links.

*The Journal of the Institute of Metals* Vol 47  
*Metallurgical Abstracts and Index to Volumes 45, 46, and 47 of the Journal* Edited by G Shaw Scott Pp viii+854 (London Institute of Metals, 1932) 80s

THIS is the first volume of the metallurgical abstracts to appear in the new form. The *Proceedings* are now published in separate volumes, and the abstracts, which are issued monthly to members, are collected into a single annual volume. This change has made for rapidity of publication. It brings with it the disadvantage that abstracts relating to a particular section of metallurgy are no longer found in a single group, but have to be sought under a number of monthly sections. It is, however, easy to find these from the table of contents, and perhaps in future years some means may be found of overcoming this drawback.

As before, the literature of the subject has been very thoroughly searched, and the abstracts are in general accurate and informative. It may be suggested that the net has been cast, on the whole, rather too widely, and that many papers are abstracted which contain nothing new. In view of the enormous number of journals dealing with the metal industries, some of them of a very ephemeral character, judicious pruning would seem to be advisable. The reader will be struck by the extensive output of metallurgical work from Russia, which has been multiplied in a remarkable degree within the last year or two.

*Rotation of a Rigid Body in Quantum-mechanics*  
By H Casimir Pp 100 (Groningen B J B Wolters, 1931)

A VERY useful account, in English, of the rather difficult mathematics underlying the theory of the quantum-mechanical motion of a rigid body is given in this monograph. The theory is, of course, essential to the proper understanding of molecular spectra, and the exposition now published is Dr

Casimir's thesis submitted for his doctorate at Leyden. The monograph does not deal with applications to any actual molecule and is by no means easy to read, but it does collect together, in a conveniently accessible form, accounts of the various mathematical methods by which the problem may be attacked, showing their equivalence, and laying special stress on the general symmetry properties of the resulting wave functions. For the specialist who wishes to study the theory of complex molecular spectra in detail (for whom the monograph was written) it should prove of great value. It is full enough to serve his purpose itself as a book of reference on most points, and for deeper study gives him the appropriate references. It is most important that in a new and growing subject such as this, the theory or definite sections of the theory should be written up again and again from every possible angle. Even the theoretical physicist with merely a general interest in the subject of molecular spectra will find much that is instructive and interesting to him brought together in this monograph, the appearance of which we heartily welcome.

*Einführung in die Erd- und Landschaftsgeschichte mit besonderer Berücksichtigung Süddeutschlands*  
Von Prof Dr Georg Wagner Pp 622+176 Tafeln (Öhringen Ferdinand Rau, 1931) 20 gold marks

THERE can be few introductory works that are more sumptuously illustrated than this, which has 503 figures, 23 page-figures of fossils, and 176 photographic plates, these latter showing for the most part two or more subjects. The figures are bold and clear, and many of the plates are from aerial photographs, so that the book is well worth looking through even by one unfamiliar with the German language.

The first part is concerned with geological processes, and here most attention is properly directed to the work of water. In the second part, dealing with earth-history, we find historical geology treated in good modern fashion, considerable emphasis being laid on facies differences, palaeogeography, economic products, and the development of landscape. Though, of course, many examples and illustrations are drawn from south Germany, the discussion of both the physical and historical aspects of the subject is by no means confined to this area, but ranges world-wide. The book summarises the modern outlook on many aspects of geology and will repay reading by teachers of the subject.

*Comparative Anatomy of Vertebrates an Outline of a Laboratory Course* By Herbert W Rand Pp 78 (Cambridge, Mass Harvard University Press, London Oxford University Press, 1931) 6s net

A BRIEF laboratory handbook based on the familiar outline of G. H. Parker, devoted to the descriptive anatomy of a typical amphibian, reptile, and mammal. To what extent such outlines instil enthusiasm for truth, critical analysis, and logical deduction is doubtful.

# Meteorite Craters

By Dr. L. J. SPENCER, F.R.S.

THE famous Meteor Crater near Cañon Diablo in Arizona (Fig. 1) is now generally believed to have been formed by the impact of a gigantic meteorite, though it still remains a subject for discussion. A good account of the crater was given by the late Sir Lazarus Fletcher in *NATURE* in 1906 (vol. 74, pp. 490-492). It is a cup-shaped depression measuring three-quarters of a mile across and with a depth of 570 feet. The rim rises gently from the surrounding desert plain to a height of 130 to 160 feet, and is strewn with huge blocks of sandstone and limestone and much fine debris. The strata exposed in the inner walls dip radially outwards from the centre, while in the surrounding country the bedding is horizontal. Around the crater, within a radius of six miles, thousands of masses of metallic nickel-iron (containing nickel, 7.33 per cent) have been collected since the first discovery in 1891. The masses found range in weight from a fraction of an ounce to 460 kilos (1014 lb.). Estimates of the total amount gathered up range from six to twenty tons. Nearly four tons of this material are preserved in the larger meteorite collections of the world. Some of the masses are surrounded by a crust of laminated 'iron-shale', which has evidently been formed by the rusting of the iron; and fragments of such material are found in abundance. Inside the crater only four smaller masses have been found, but there are indications of the 'iron-shale'.

A point of special interest about these Cañon Diablo irons is the presence in some of the masses of small diamonds, both black and white; and it was doubtless this observation that suggested to H. Moissan his experiments on the artificial production of diamond. Moissan also detected in the iron the presence of native carborundum (silicon carbide), which as a meteoric mineral has been named moissanite. Other rarer constituents of this meteoric iron are platinum metals. One assay yielded platinum 3.65 and iridium 14.95 grams per metric ton, but some other later trials gave negative results.

The view that the crater was formed by the impact of a gigantic meteorite, perhaps 500 feet in diameter and weighing more than a million tons, led to the belief that such a mass would be found buried in the crater and would well repay mining operations. Mining claims were taken out and several trial borings were put down in the centre of the crater. In the bore-holes undisturbed rock was met at depths of about 650 feet, but nothing of value was found—only traces of oxidised iron and nickel. Another bore-hole was put down

several years later under the southern wall of the crater, on the supposition that the meteorite had entered at a slanting angle; but again without any decisive result. After passing through 30 feet of iron-shale cementing fragments of metamorphosed sandstone, the drill stuck, at a depth of 1376 feet, presumably against some hard object, which was thought to be perhaps the main mass of the meteorite. In these borings there was encountered a large amount of 'rock-flour', consisting of crushed grains of quartz from the sandstone; and, in places, some pumice-like material, consisting of silica-glass, which was no doubt formed by the fusion of the sandstone.

In this region there are no volcanic rocks and no indications of volcanic or solfataric activity, so

FIG. 1.—Meteor Crater, near Cañon Diablo, Arizona. Air photograph from north-west of the crater, almost in the direction and angle at which the meteorite is supposed to have struck. From the *National Geographic Magazine*.

that a volcanic origin of the crater is ruled out. The idea that it was formed by a steam explosion is, also, not supported by the facts; and still less a recently expressed opinion that the crater owes its origin to the solution of the limestone and is of the nature of a sink-hole. The intimate intermingling of huge blocks and finely powdered sedimentary rocks with meteoritic material indicates that there must be a close connexion between the fall of a meteorite and the formation of the crater; and the fusion of the sandstone, giving silica-glass, could no doubt have been effected by the heat generated by the impact of the mass. With the development of a temperature (1400°-1800° C.) sufficient to fuse quartz, and the presence of water in the surrounding rocks, explosive action from this secondary cause must have helped in making the crater and scattering the fragmentary material. Such a 'back-fire' would explain why the meteorite fragments are found only outside the crater, and it may also be the cause of the upward tilting of the strata in the crater-walls.

A small meteoric stone entering the earth's atmosphere with planetary velocity (up to 45 miles per second) is quickly checked by the resistance of the air, and it reaches the earth's surface with the velocity of an ordinary falling body of about 70 metres per second. But with an enormous mass of metal travelling at such a velocity the momentum is much greater, and it would be difficult to conceive what would be the actual state of affairs (any unfortunate observer would have no opportunity of recording his observations). Meteorites

with the surrounding ground, and around it there is no sign of a crater.

Until quite recently the crater in Arizona was the only known example of this type of feature on the earth's surface—a feature which, though on a much smaller scale, has been compared with the craters of the moon. In 1921 a mass of meteoric iron was found near Odessa in Ector Co., Texas, and since then it has been noticed that the spot is marked by a crater. This is roughly circular in outline, with an average diameter of 530 feet. The

actually observed to fall have made holes in the ground usually not more than one or two feet in depth. The largest meteorite of which the fall has been observed is a stone of 820 lb. which fell at Paragould in Arkansas on Feb. 17, 1930. This penetrated clayey soil to a depth of 8 feet, scattering clods to a distance of 50 feet in the pasture. A stone of 293 kilos (645 lb.) which fell at Knyahinya in Czechoslovakia on June 9, 1866, penetrated to a depth of 11 feet. On the other hand, the largest known meteorites, all of which are irons not observed to fall, have been found by reason of them being partly exposed at the surface of the ground. The 60-ton Hoba meteorite discovered in South-West Africa in 1920 has its upper surface level

rim is about 18 feet above the bottom of the hole, but only 2 or 3 feet above the surrounding desert plain, where horizontally bedded limestone is exposed. The steep inner slopes show the limestone dipping at 20°-30° away from the centre. Numerous pieces of 'iron-shale' and a few small pieces of metal have been found on the surface of the rim. The various suggested modes of origin of this crater that have been discussed include: (1) volcanic explosion; (2) salt dome; (3) expansion by hydration of anhydrite; (4) explosion of gas; (5) fall of a meteorite.

A group of similar but smaller craters on the island of Oesel (Esthonia) in the Baltic has recently been surveyed in detail and borings made. The main crater, in which there is a small lake, is 110 metres across and its rim is 6 metres above the

\* Figs. 2-5 are taken from Mr. A. R. Alderman's paper on the Henbury craters, published in the *Mineralogical Magazine*, March 1932, vol. 23, pp. 19-32.

surrounding ground, while inside the depth is 50-60 metres. On the inside walls the beds of dolomite rock dip away from the centre, and there is a zone of pulverised rock. Six other small craters, 14-39 m.

radially outwards over a radius of 60 kilometres. In the centre of the devastated area was discovered a group of ten craters, with diameters of 10-50 metres and a mean depth of 4 metres. Boring

inside the craters to a depth of 10 metres in the frozen ground yielded no meteorites.

In the instances briefly described above we have two cases of single craters associated with meteoritic material and two cases of groups of craters without meteoritic material. A more recent discovery is that near Henbury, about 50 miles south of the MacDonnell Ranges, in the very centre of Australia. Here a group of thirteen craters is associated with abundant meteoritic material, and the evidence of a connexion between the two is much more conclusive. The locality was visited in May 1931 by Mr. A. R. Alderman, of the University of Adelaide, and his description of the craters is published in the March issue of the *Mineralogical Magazine*. Eight hundred pieces of meteoric iron were then collected. In June 1931, a visit was made by Mr. R. Bedford, of the Kyancutta Museum,

FIG. 4.—Plan showing the general distribution of the craters and of the meteorite fragments around them at Henbury Central Australia.

across, are in the vicinity. Suggested origins that have been considered in this case are: (1) artificial earthworks; (2) gas explosion; (3) oozing out of a bed of clay; (4) Karst weathering of the dolomite; (5) expansion of salt or anhydrite; (6) fall of a meteorite. In this case no trace of meteoritic material was found, but in spite of this, a meteoric origin of the craters has been thought probable.

The great Siberian meteor of June 30, 1908, left its mark in a series of craters in the ground, but no meteoritic material has been found. Expeditions to the inhospitable region on the Stony Tunguska river in central Siberia were led to the spot by the devastation of the pines, forest trees being felled

FIG. 5.—Typical fragments of meteoric iron from the meteorite craters at Henbury, Central Australia (with scale of inches).

South Australia, who has sent 542 pieces of the iron, together with fragments of 'iron-shale' and scoriaceous silica-glass, to the British Museum (Natural History). A selection of Mr. Bedford's material is now exhibited on loan in the Mineral Gallery of the Natural History Museum at South Kensington.

The Henbury craters show an irregular distribution within an area of half a mile square. The three larger ones are adjacent, and the largest measures 220 by 120 yards across, with a depth of 50 to 60 feet. The others are approximately circular in outline, with diameters ranging from 10 to 80 yards. Owing to the craters acting as collecting pans for rain-water in this arid region, the spots are marked by the growth of mulga trees, acacias, and coarse grass. This helps to locate the craters, which with their gently sloping outer surfaces are not very conspicuous until the interior is viewed from the edge of the rim. Radiating outwards from some of the craters into the plain are five or six low ridges of sandstone, which may have some relation to the percussion of the meteorites. The steep inner walls of the craters consist of powdered rock and shattered blocks of sandstone, quartzite, and slate. The masses of iron found scattered around these craters range from a fraction of an ounce to 170½ lb. in weight. In one area of 6 feet by 6 feet more than a hundred pieces were collected. Many of the smaller pieces are flaky and shell-like, and are probably the result of the breaking down of larger masses by weathering. Laminated 'iron-shale' in pieces up to several pounds in weight has been found in association with the irons, and it is evident that this has resulted by oxidation of the

iron. As at the Meteor Crater in Arizona, it is remarkable that very little meteoritic material has been found within the crater-walls. Here only two pieces of iron have been found inside one of the craters; and in one of the smaller craters a bore-hole through fine silt down to coarse rock fragments at a depth of 8 feet yielded no mass of iron. Outside the craters were found some fragments of scoriaceous glassy material, which in micro-sections is seen to consist of silica-glass impregnated with iron oxide. This resembles the Arizona material, and was no doubt formed by the fusion of the sandstone by the impact of the meteorite.

At Henbury, with the numerous masses of iron scattered around several craters, there must have been not a single meteorite, but a shower. Further exploration of the locality is to be made this year, and it is hoped that more data will then be available. In the meantime any speculation on the mechanics of the formation of such craters must involve many assumptions. Mr. Alderman is of the opinion that the craters were formed ages ago, while Mr. Bedford believes that they are comparatively recent. The latter mentions that the old blacks will not camp near the place, and that they call it "chindu chinna waru chingi yabu", meaning "sun walk fire devil rock"; which suggests that the natives have some tradition of the fall.

### Implements of Chinese Fossil Man

THE scientific reports on the discovery of implements and remains of fires in association with the fossil man *Sinanthropus* have now been published by the Geological Society of China.\* It is therefore possible to appreciate the significance of this addition to our knowledge of one of the earliest representatives of the human race. There are no traces of glacial or pluvial episodes in the superficial deposits of eastern China to mark horizons; but the distribution of the fossil mammals seems to show that *Sinanthropus* is of Lower Pleistocene age.†

The disintegrated charcoal from wood fires occurs abundantly in old hearths resembling those which are now familiar in the Palaeolithic settlements of Europe. In one place it is scattered throughout a deposit seven metres thick, and Prof. Breuil remarks that the fire was probably replenished continuously during the long period which is represented by so great a thickness of residue. Among the charred remains are numerous burnt bones and stones, including implements. Deer antlers were cut into short lengths by flakes of stone, aided by burning at the lines of section. The bases of antlers seem to have been used as hammers. The

young antler fixed to a piece of skull was used whole, the base being trimmed for a convenient handle. Bits of brain-case seem to have been made into cups; some of the upper jaws were evidently used as files, and some of the lower jaws as small picks, with the coronoid process as working tip. The long bones were regularly broken for the marrow, and some of them seem to have lost only one end, where a stone would be fixed as in a handle.

The stone implements are rudely made of flakes which have been taken from stones found in the river below, and from quartz which occurs on the opposite side of the valley. They are well described by Mr. Pei, and are illustrated with both photographs and diagrams. They are all small, the largest not more than 15 cm. in greatest diameter, and they are at least as varied in shape as the implements met with in the Mousterian deposits of Europe. There are cores and flakes, showing that the implements were made on the spot, and some of the cores themselves are retouched for use.

As the Choukoutien deposits obviously represent a human dwelling-place, while the only remains of *Sinanthropus* hitherto discovered in them are skulls and jaws, Prof. Breuil discusses the suggested possibility, that the fires and implements were made by a higher type of man who collected the skulls of a lower race as trophies of the hunt. He wisely rejects this suggestion, and looks forward to the discovery of numerous still more primitive ancestral men with real human intelligence.

\* D. Black, "Evidences of the Use of Fire by *Sinanthropus*", *Bull. Geol. Soc. China*, vol. 11, pp. 107, 108; 1931. H. Breuil, "Le Feu et l'Industrie Lithique et Osseuse à Choukoutien", *tom. cit.*, pp. 147-154 (also in *L'Anthropologie*, vol. 42, pp. 1-17; 1932). W. C. Pei, "Notice of the Discovery of Quartz and other Stone Artifacts in the Lower Pleistocene Hominid-bearing Sediments of the Choukoutien Cave Deposit", *tom. cit.*, pp. 109-139, pls. I-III.

† W. C. Pei, "The Age of Choukoutien Fossiliferous Deposit", *Bull. Geol. Soc. China*, vol. 10, pp. 165-178; 1931. C. C. Young, "Die Stratigraphische und Palaeontologische Bedeutung der fossilen Nager-tiere Chinas", *tom. cit.*, pp. 159-164, with 3 tables.

Piltdown man (*Eoanthropus*) is at least as old as *Smantropus*, if not older, and was shown long ago by Mr Charles Dawson and myself to have made both stone and bone implements, and to have split bones, doubtless for extracting the marrow. More recently, burnt flints have been

noticed in the Piltdown gravel, and not long ago I found one such flint which is indistinguishable from the 'pot boilers' of later periods. The beginning of human arts, indeed, dates back to immense antiquity, before man had assumed his present form.

A SMITH WOODWARD

### Obituary

SIR WILLIAM WATSON CHEYNE, Bt, F.R.S.

IN spreading the doctrines and technique of antiseptic surgery, Joseph Lister had no more efficient nor more ardent disciple than William Watson Cheyne, who died, after a long illness, on April 19 last, in the eightieth year of his age. From very humble beginnings, Cheyne, by sheer ability, perseverance, and high principle, reached the summit of the surgical profession in Great Britain and commanded the respect of the whole medical world.

Not only was Cheyne a practical operating surgeon, but under the influence of Lister he was also a pioneer of bacteriological research in England, and did more than anyone else to diffuse the bacteriological knowledge which in the seventies and eighties of last century had accumulated at an astonishing rate in Germany and France. In this advance, England played almost no part, if we except Lister himself. At first we concerned ourselves with research in histology and physiology, and at a later period the energy of English workers was directed by the writings of Virchow and the growth of the cellular pathology. We had not learned the snares of bacteriological technique, and even Lister himself, working alone and with imperfect methods, fell into bacteriological errors which, however, he later handsomely admitted and corrected. Watson Cheyne was closely associated with Lister, and although he did not publish many separate memoirs on bacteria, he incorporated much original research in his surgical works and particularly in his "Antiseptic Surgery: its Principles, Practice, History, and Results", 1882, pp 616.

Cheyne also did much to introduce English students to bacteriology by his translation of the second edition of Flügge's famous "Fermente und Microparasiten". This translation was published in 1890 by the New Sydenham Society under the title "Micro-organisms with Special Reference to the Etiology of the Infective Processes", and ran to 826 pages. Cheyne also edited an important collection of classical bacteriological papers under the title "Recent Essays by Various Authors on Bacteria in Relation to Disease", 1886. By these works Cheyne became widely known, but at a relatively early date he was forced to relinquish his scientific work as he had to earn his living. In those days there were no whole-time paid pathological—far less bacteriological—posts in the country except in the four Scots universities. Cheyne therefore took up surgery as a practical profession, but he continued to be a voluminous writer, and most of his writing was of high medical

quality. One of his chief works was that in conjunction with F. F. Burghard, and entitled "A Manual of Surgical Treatment", second edition, 5 vols, 1912–1913. For many a day this was a standard work.

As a spectacular operator, Watson Cheyne could not be classed alongside several surgeons even in his own day, but he did all his work in the most conscientious way, and the welfare of his patient was his first and last concern. He thus early acquired a name for surgical rectitude, and his opinion and skill were soon in such demand that he acquired a very large practice, and for many years led an exceedingly busy and useful life. Lister's mantle may be said to have fallen upon Watson Cheyne, who bore it nobly and well, and the pupil was a credit to the great founder of the antiseptic principle in surgery.

Sir William Watson Cheyne was born—at sea it is said—on Dec. 14, 1852, the son of Andrew Cheyne and his wife Eliza, daughter of the Rev. William Watson, minister of the far-away island of Fetlar in Shetland, and in the manse of this wind-swept island Cheyne spent his boyhood and learned to love the sea. He always visited Shetland whenever he could, and after the *Sturm und Drang* of a long professional and busy life in cities, he retired to the Ultima Thule where he had spent so many happy years, and settled once more in Fetlar until a year or two before he died.

Cheyne studied medicine in Edinburgh and graduated M.B., C.M. there in 1875. He then went to Vienna and Strassburg, and thereafter he became house surgeon to Joseph Lister, at that time professor of clinical surgery in Edinburgh, and nearing the height of his fame. When, in 1877, Lister was invited to take up the duties of surgeon at King's College, London, he asked Cheyne to accompany him to be his first house surgeon. Cheyne took the F.R.C.S. diploma in 1879, and in due course was elected assistant surgeon at King's College Hospital. He finally reached the position of consulting surgeon and retired.

When the South African War broke out Sir William at once volunteered for active service and was appointed a civil consulting surgeon. In the War of 1914–1918 he was at first Consulting Surgeon to the Royal Navy and, later, Surgeon-General, R.N. Finally, in 1918, he attained the rank of Surgeon Rear Admiral. He was created baronet on July 20, 1908, and was appointed Surgeon-in-Ordinary to H.M. the King. In 1914 he was elected president of the Royal College of Surgeons, and he was the first recipient of the Lister Memorial Medal in recognition of his distinguished contributions to surgical science. Retiring from practice, he was

elected M P for the Universities of Edinburgh and St Andrews in 1917, and in 1918 he became M P for the Scottish Universities

Sir Wilham was married twice, and is succeeded in the baronetcy by his elder son, who bears the name of Joseph Lister Cheyne W B

#### MR A M LEA

A FINE naturalist and a lovable man passed away, suddenly and painlessly, from cerebral hæmorrhage, at Adelaide on Feb 29 Arthur Mills Lea, born at Sydney sixty-three years ago, at an early age collected butterflies Leaving the State school when still a boy, and encouraged by the veteran collector and curator, the late George Masters, he extended his field of action to beetles and other insects, and soon every spare moment was given to collecting and taking infinite trouble to get his specimens identified

Lea's first post was that of assistant entomologist to the late A Sidney Oliff, in 1891 Four years later he was selected as Government entomologist to Western Australia, and in 1899 was promoted to a similar position in Tasmania Here he established a high reputation as an economic entomologist in the great fruit-growing State But throughout, Lea always used his opportunities and spare time in diligent collecting and classifying his favourite order, the Coleoptera, especially studying the most difficult family of all, the weevils—so intimately associated with plant life He soon became the Australian authority on this group, and to-day more than 2000 Australian and New Guinea weevils have been described and named by him (about twice as many as the number recorded in Masters' Catalogue of 1886)

In 1911, Lea was appointed entomologist to the South Australian Museum where he made the insect collection one of the finest in Australia—its value greatly enhanced by the large number of his added types In 1924 he was given a year's leave of absence to undertake a research on behalf of the *Levuana* Committee, when the moth of that name threatened the Fiji copra industry, and he traversed Queensland, New Guinea, Java, Malaya,

and Borneo in the study of a biological control of the pest

For many years Lea was the centre of inquiry from entomologists the world over, on determinations and nomenclature of insects His work extended over the whole order, including especially the important families of Scarabæidæ, Chrysomelidæ, Coccinellidæ, and Malocodermidæ In a word, Lea's close and detailed knowledge of Australian insects raised him to a unique position This was the more praiseworthy as being almost wholly the result of self-help and sustained industry, for it included the study of Latin, French, and German, languages not learnt at school, and a special gift for drawing, utilised in his numerous papers Lea described *no less than 5432 species of insects*, chiefly Australian, but including many from New Guinea, Fiji, New Caledonia, Lord Howe and Norfolk Islands Idle moments were unknown to him Daylight was fully utilised for the examination of material, evenings for correspondence or preparing manuscript for publication Yet he found time to serve on the Council of the Royal Society of South Australia and to act as assistant editor of its *Transactions* His loss is irreparable, for no other man possessed a tithe of his wide knowledge of the Australian insect fauna, nor would be so generous of help Like most enthusiasts, Lea had a special faculty for inspiring enthusiasm in others H J CARTER

WE regret to announce the following deaths

Mr R H Adie, formerly secretary of the School of Agriculture, University of Cambridge, on May 18, aged sixty-seven years

The Hon Mrs Huia Onslow (Muriel Wheldale Onslow), University lecturer in plant biochemistry in the University of Cambridge, on May 19

Dr Goddard H Orpen, president of the Royal Society of Antiquaries of Ireland, and an authority on the early history and antiquities of Ireland on May 15, aged eighty years

Dr J C Thresh, formerly medical officer of health to the County of Essex, and an authority on public water supplies, on May 23, aged eighty-one years

### News and Views

#### Evariste Galois

"No episode in the history of thought", says Dr G Sarton, "is more moving than the life of Evariste Galois—the young Frenchman who passed like a meteor about 1828, devoted a few feverish years to the most intense meditation, and died in 1832 from a wound received in a duel at the age of twenty He was still a mere boy, yet within these short years he had accomplished enough to prove indubitably that he was one of the greatest mathematicians of all time" The tragic story of Galois was told by Dr Sarton in the *Scientific Monthly* for Oct 1921 Born at the village of Bourg-la-Reine near Paris on Oct 25, 1811, he was the son of a schoolmaster and mayor, who had married a lawyer's daughter of good education, said

to have been "generous to a fault and original to the point of queerness" Taught at first by his mother, in 1823 Galois was sent to the Collège Louis-le-Grand, and after twice failing to gain admission to the École Polytechnique, in 1829 entered the École Normale At school he had been conspicuous for the qualities he had undoubtedly inherited from his mother, and was little understood by his teachers "The *furor* of mathematics possesses him", one of them wrote His career at the École Normale was short Embittered by his failure to attract attention to his work, and distracted by the suicide of his father, he became embroiled in political discussion and he was expelled His outspoken republicanism afterwards led to his imprisonment, and to his youthful miseries was added

that of an intrigue, which probably led to the duel which cost him his life. The duel took place on the early morning of May 30, 1832, and he died next day in the Hôpital Cochin. His complete works fill only sixty-one small pages, but a French geometer, publishing a large volume some forty years after Galois' death, declared that it was simply a commentary on the latter's discoveries.

#### Faraday and Benzene

THE Royal Institution audience at the Friday evening discourse on May 20 had a stimulating experience when Prof. Henry E. Armstrong addressed them with "Faraday at the Sign of the Hexagon" as his subject. "Coal Colour and Constitution" was the alleged theme of the evening, but this venerable Lewis Carroll of chemistry allowed himself freely to be led only by the spirit of the moment. With the lecture room decorated like an Eastern bazaar, with fabrics of every pattern and hue, the 'lecturer' was evidently content to appear as a benevolent 'high priest of colour', wearing himself as regalia a waistcoat of the genuine nursery sky blue and pink. The ordinary symbols of the orthodox chemist were discarded for this occasion, "as people won't take the trouble to understand their meaning", so straight-chains and ring compounds were replaced by the backbone of a mackerel and by a whiting with tail in mouth ready for the kitchen, also buttons on safety-pins deputed for the unwieldy formulæ of the dyes chemist, all used to illustrate the genealogy of benzene, that "pallid infant of the sober Faraday", "taken as mistress by Hofmann", with progeny the "gentle Aniline" and her numerous offspring whose "hectic and chromatic careers" were vividly described. Nor must Miss Hook of Holland be forgotten, who left her seat by the chairman to display her famous many-hued petticoats, as illustrations of the dyes which the chemists' control of colour has produced from the same base.

#### Statue to Trevithick

ON May 17, at Camborne, Prince George unveiled a statue of the eminent Cornish engineer, Richard Trevithick, which has been erected in front of the Free Library. Trevithick was born in the neighbouring parish of Illogan in 1771, but soon after his birth his parents removed to a cottage in Camborne, which is now being preserved as a memorial, and after his marriage Trevithick himself had a house and workshop in Fore Street. Like his father, he was a mine engineer, but he will always be remembered as a pioneer in the use of high pressure steam and of the locomotive. The statue which has been erected depicts him holding a model of his first road locomotive. Previous to the unveiling of the statue, Prince George had attended a luncheon at the Camborne School of Mines, at which there were representatives of the county of Cornwall, various engineering and scientific societies, and the railways. The project for raising a memorial to Trevithick was started in 1911, but owing to the War and other causes its completion has been much delayed. The other memorials to Trevithick include a window in Westminster Abbey, a scholar-

ship at the University of Manchester, the Trevithick premium of the Institution of Civil Engineers, and the tablet in Dartford Parish Church, in the grounds of which he was buried in April 1833.

#### British Broadcasting

In a thoughtful address at the Royal Institution on May 13, Sir John Reith indicated some of the reflections and conclusions forced upon him by his ten years' experience of broadcasting. These bore mainly upon the influence of the peculiar constitution of the British Broadcasting Corporation upon its effectiveness and success. The rationalised nationalisation of that body gives it freedom from the cramping and cumbersome system of a government department, while yet retaining a certain degree of public control. It can proceed to carry out the terms of its commission as unhampered as any private enterprise, but the objections to private enterprise are eliminated by the public control of matters of major policy. Monopoly, Sir John regards as an essential of the efficient national system not only on economic and administrative grounds, but also because competition in broadcasting reduces programmes to the level of the greatest demand, and that would have cut out much of the service to music and education which the B.B.C. has been able to render. Finally, personal direction by an individual aware of his responsibility and having the courage of his convictions, leads, as no form of government depending upon the suffrages of electors can lead, to decisive and consistent action.

UNDER such a regime, Sir John Reith foresees a great future for broadcasting. It is not without significance that so many other countries have, with adaptation to local needs, copied the work and form of the B.B.C. Britain appears to have sensed in this respect a need that was common to all nations belonging to the European culture, perhaps because through this system democracy may at last be able to come to its own. Nationally, he said, this obtains because the peculiar nature of the medium imposes sincerity and moderation on speaker and thoughtfulness on hearer, and because those who have something real to contribute to society are brought into direct contact with, not the masses, but the individual members of that society. Internationally, it obtains because ether waves do not stop at frontiers, so that the foreign listener must come, if not to agree with, at least to respect, points of view different from his own, presented to him with the sincerity that carries force and without the violence that provokes it.

#### The Expanding Universe

IN his Ludwig Mond lecture, delivered at Manchester on May 9, on the subject of "The Expanding Universe", Sir James Jeans began with a review of the system of galaxies, our knowledge of which has been greatly extended by recent work with the 100-inch reflector at Mt. Wilson. From these results, he concludes that some two million nebulae lie within a distance of 140,000,000 light-years—a sphere of observation which bears the same ratio to the whole

of space as the Isle of Man to the whole surface of the earth. Reference was then made to the conclusions of Friedmann and Lemaître that the equilibrium of such a universe would be unstable, and if expansion started it would continue. Sir James conjectures that the initial impulse which started the expansion may have arisen in the process of the condensation of the primeval chaotic gases into nebulae. Spectrograms of the distant galaxies indicate such an expansion, the rate of recession being about 105 miles per second at a distance of a million light-years, and increasing in the same proportion as the distance, so that it attains the amount of 15,000 miles per second for the most distant nebula yet measured.

ALLUSION was then made to the difficulty of reconciling this rapid recession with a past duration of the universe extending to millions of millions of years. Sir James has himself given strong reasons in favour of such a past duration, but he now admits that it may be necessary to abandon it. There are, however, some alternatives, there might have been a long period before the recession got fairly started, or the spectral shift that appears to indicate recession may be due to some other cause. Allusion was made to Sir Arthur Eddington's attempt to evaluate the cosmical constant, and so obtain a theoretical value for the rate of expansion, he obtained a value quite close to the observed rate. Sir James noted that this result, while intensely interesting as linking up the largest and the smallest objects of observation, is still a matter of controversy, and cannot be accepted as certain.

#### Hughlings Jackson Memorial Medal

DR HUGHLINGS JACKSON, who died in 1911, gave the first Hughlings Jackson lecture that was founded in 1897 in his honour by the Neurological Society of London. With a few intervals, as during the War, this lecture has been given triennially, by an eminent neurologist or physiologist. Last year the Section of Neurology of the Royal Society of Medicine decided to form a fund to endow the lectureship with a gold medal and an honorarium of a hundred guineas triennially, and subscriptions were invited by a committee of which Mr Leslie Paton was chairman and Dr Wilfred Harris treasurer, 146 subscribers from many parts of the world produced a sum of just over £1200, which has been handed over to the Royal Society of Medicine, after paying for the design of a gold medal by Mr Percy Metcalfe, the work being carried out by the Royal Mint. Sir Charles Sherrington, who gave the last lecture, on "Quantitative Management of Contraction in Lowest Level Co-ordination", has been awarded the first medal.

THE first Hughlings Jackson Memorial Medal, with the honorarium, was formally presented to Sir Charles Sherrington on Thursday, May 19, by Dr Watts Eden, president of the Royal Society of Medicine. Before doing so, Dr Stanley Barnes, president of the Section of Neurology, introduced Sir Charles Sherrington as an original member of the Neurological Society in 1886, and referred to Sir Charles's fame as an experi-

menter. He also called upon another original member of the Society who was present, Sir James Crichton-Browne, to give some personal recollections of Hughlings Jackson. Sir James recalled that in the early 'seventies Jackson had regularly visited the West Riding Asylum at Wakefield, where Sir James was then medical superintendent, and contributed several articles to their reports. After Sir James left Wakefield for London, he, with Hughlings Jackson, Ferrier, and Bucknill, founded the neurological journal, *Brain*. After Sir Charles Sherrington's reply, thanking the Royal Society of Medicine and the Fund Committee for their valuable prize, Mr Leslie Paton presented Dr Watts Eden, for the Royal Society of Medicine, with two replicas of the Jackson Medal, in toned silver, suitably framed.

#### Two-way Television

WHEN the possibility of television was recognised, the first application that suggested itself was to show the image of a person hundreds of miles away. A natural development was to superpose a television on a telephone system so that the hearer could both see the speaker and hear him talking. This latter method is used daily by the B B C in the television radio broadcasts. A successful experiment showing the combination of ordinary telephony with two-way television was demonstrated to the Press in Paris on May 19, and an account of it appeared in the *Times* on the following day. The television apparatus used was supplied by the Baird Television Corporation. Infra-red rays are obtained by filtering artificial light through ebonite screens. They fall on both the speaker and the hearer. Only invisible rays are used to produce the electrical impulses in the connecting wires. At the ends of the line they are converted into light rays and focused on screens. It is difficult for either the speaker or listener to realise that his head and shoulders are in full view of the other. The visual screens are ten inches long by five inches broad. As the scanning disks make 750 revolutions per minute,  $12\frac{1}{2}$  complete images per second appear on the visual screen. At this speed there is little flickering. The features are easily recognisable and the play of expression on the face is remarkably clear. The movement of the lips can easily be followed. If necessary, the 'fineness' of the images could be improved by increasing the number of dots. In the near future, public communication combined with television on a commercial basis will be started between Paris and Lyons. The Baird-Nathan Company is exploiting this system in France, and later on it is hoped to connect Paris and London in this way. A form of two-way television was demonstrated in New York by the Bell Telephone Co. on April 9, 1930 (*NATURE*, May 31, 1930).

#### London Power Supply

THE Central Electricity Board was created by the Act of 1926, and was given great powers to co-ordinate generation throughout the whole of Great Britain, including the London area. In 1929-30 the load for this area, excluding the railway and tramway re-

quirements, was supplied by 58 generating stations. Of these stations, 27 small ones supplied only four per cent of the total load, the average generating cost per unit being more than 1 5d. Five groups of large stations supplied 66 per cent of the total load, the average generating costs being 0 466d per unit. When the extensions at Barking and the new stations at Battersea and Fulham come into operation, even better results will be obtained by the larger stations. The fundamental geographical feature from the point of view of electrical generation is the Thames Valley, with its abundant supply of water for condensation purposes and its facilities for the transport of waterborne coal. In a lecture by J. D. Peattie, published in the *Electrician* for May 6, an account is given of the interconnexion of the generating stations in the London area. Within a radius of ten miles from Charing Cross, there are now hundreds of lattice towers supporting stranded cables for the grid at 132 kilovolts and for connecting stations at 66 and 33 kv. There is a notable river crossing between Barking and Northfleet, where two towers, 487 feet high, will give a clearance under the wires at high water of 250 ft on a span of 3060 ft. These towers are the highest on the grid and will carry two double circuits. They are specially painted, and will be illuminated at night to give warning to aircraft flying along the Thames Valley. On the way to Southend one of them is now a conspicuous landmark.

#### The Hannah Dairy Research Institute

A BRIEF account of the researches already carried out at the recently established Hannah Dairy Research Institute, Kirkhill, Ayr, is given by the director, Dr N. C. Wright, in the *Ayrshire Cattle Society's Journal*, vol. 3, No. 1. An investigation into the incidence of certain bovine diseases, especially tuberculosis and milk fever, has been commenced, and, as a result, recommendations have been made which should lead to the elimination from tested herds of a large proportion of the animals reacting positively to the tuberculin test. Inquiry is also being made into the length of life of milking cows in Scottish herds and into the main causes which lead to the unremunerative disposal of stock. The problems of the utilisation of surplus milk and of milk by-products also received attention. Investigations on the biological side require laboratory accommodation, which has only recently become adequate with the completion of the buildings at Kirkhill. They will include a re-investigation of the protein requirements of dairy cows, and an investigation of the physiology of lactation. In addition, the problems involved in improvement of the dairy stock by selective inbreeding and in the methods used in condensing and drying milk, separated milk, and whey will be examined. Two-thirds of the income of the Institute is received in the form of a grant from the Development Commissioners, but the remaining third must be raised from non-government sources. It is estimated that £2000 will be required annually, and it is hoped to secure an endowment fund which will supply an assured income of this order.

#### Anthropological Bibliography

ANTHROPOLOGY in particular among the sciences is not well served in the matter of indices and bibliographies, though what is needed is, perhaps, co-operation rather than extended effort. There is already in existence a number of bibliographies dealing each with some one or more departments of anthropological science. Some of these overlap, and none can be called really complete. The latest of these has been compiled by M. Joseph Nippgen, librarian of the Société de Géographie of Paris, and has appeared in *L'Ethnographie*, it may be obtained separately from the Société d'Ethnographie de Paris. It covers contributions to general and comparative ethnology, and folklore and comparative religion, while ethnographical papers and books dealing with specific geographical areas are grouped under continents. A few items in archaeology and physical anthropology are included. This bibliography has the additional advantage that a considerable number of the items are analysed at some length by the compiler. There is, unfortunately, no indication of the period of publication covered by the compilation as a whole, though the latest date appearing is 1929. The current issue of *L'Anthropologie* (T. 40, Nos. 5-6) is devoted entirely to an index of vol. 21-40 of that periodical, issued for the years 1910-31. The index is divided into two parts, of which the first contains a list of authors in alphabetical order and the second is a subject index. Titles of original communications and *variétés* are distinguished from book reviews by a difference in type, but no distinction is made between the names of authors of books reviewed and of original communications. In consequence, the arrangement gives undue prominence to what, from the point of view of most who will wish to consult *L'Anthropologie*, must be regarded as much in the nature of second-class matter. Notwithstanding this inconvenience, the index is a great boon, and an example that might well be followed with advantage by many more of the British scientific periodicals which have a long run.

#### New Mayan Site in Yucatan

A RUINED Mayan city of enormous proportions, previously unknown, has been discovered in southern Yucatan by Mr. C. L. Lundell, a representative of the American Chicle Development Company. The ruins are situated in the south-east corner of Campeche and are difficult of access, but under an arrangement with the Mexican Government they have been inspected by Dr. Sylvanus G. Morley, accompanied by a party of five. The city has been named Calakmul, "The Two Adjacent Hills", by its discoverer. In Dr. Morley's report, as circulated by Science Service, of Washington, D.C., the site is said to contain many more sculptured monuments than any Mayan city hitherto known. There are no less than one hundred and three stelæ with sculptured figures and hieroglyphs. Some of the stelæ are of high artistic merit. Fifty-one are dated, and one-half of these have been deciphered. It is evident that the city was once a

great religious centre and a place of outstanding importance in the Old Empire of the Mayas

#### Neanderthal Man in Palestine

A CABLE received by Miss D A E Garrod, director of the joint expedition of the British School of Archaeology in Palestine and the American School of Prehistoric Research, announces a further discovery of skeletons in the Mugharet-es-Sukhul cave by Mr T McCown. With those previously discovered, the number of individual skeletons now amounts to seven, presumably the relics of a collective burial. The remains are enclosed in a hard breccia in which are also found a large number of stone implements of Mousterian type.

#### New Atlantic Flight

IN 1928, Miss Amelia Earhart (Mrs Putnam) crossed the Atlantic from west to east in an aeroplane with two others, the late Mr Wilmer Stultz and Mr Louis Gordon. On Saturday, May 21, she landed near Londonderry, Northern Ireland, having completed a flight from Harbour Grace, Newfoundland, in about fourteen hours. Miss Earhart is thus the first woman flying alone to cross the Atlantic, and she has also set up a new record for the shortest time for the flight. Her machine was a Lockheed Vega monoplane with a Wasp engine of 420 h.p. Four hours out from Harbour Grace, a leaky joint developed in the exhaust of the engine, causing other parts to work loose and set up vibration. There was also danger from petrol leaking into the cockpit from the petrol gauge. For about five hours during the night, Miss Earhart was flying 'blind' through bad weather, and during this period her altimeter broke down. In spite of these difficulties, Miss Earhart reached the west coast of Ireland and, being uncertain as to her exact bearings, turned north until she saw the country sloping down to the sea. She landed successfully close to Londonderry.

#### Lewis Evans Collection at Oxford

THE Committee of Management of the Lewis Evans Collection of Scientific Instruments has issued its Annual Report. Details are given of the important collection of astronomical, optical, magnetic, and mathematical instruments presented by the Royal Astronomical Society of London. This collection is especially valuable as illustrating the period in the history of astronomical measuring which immediately preceded the time when photographic methods began to be employed for the accurate determination of stellar positions. A very notable addition to the collections illustrating the original association of the Old Ashmolean Museum with the study of natural history in Oxford has resulted from the discovery of a part of the great Lhwyd collection of fossils, which had been lost for two centuries, in a cabinet deposited with the Lewis Evans Collection by Oriel College. These fossils, most of which are in their original wrappings inscribed with data, are of the highest historic interest as being part of the first geological collection in Oxford, and especially as being the original type

specimens described and in some cases figured by Lhwyd in his classical work on British palæontology.

#### Barn Owl Census, 1932

THE diminishing number of barn (or white) owls in England and Wales in recent years is giving concern to agriculturists and students of bird life. In order to obtain information as to the facts of the case, the Royal Society for the Protection of Birds is instituting a census of barn owls breeding during the summer of 1932, and helpers are required in every part of the country to find out and record where in their own localities the birds are nesting. All who may be willing and able to assist the inquiry by undertaking to report upon a definite area, are asked to communicate with Mr G B Blaker, Gaveston Place, Nuthurst, nr Horsham, Sussex, who is organising the work, and to indicate the extent of the area to be allotted to them. Census forms, with suggestions as to how the work may be carried out most easily and effectively, will then be forwarded. It is hoped that valuable information will thus be obtained as to the status of this useful bird.

#### Prevention of Cherry Fruit Fly

WITH the object of preventing the introduction of the cherry fruit fly into England, the Ministry of Agriculture and Fisheries has issued an order (under the Destructive Insects and Pests Acts, 1877 to 1927) which regulates the importation of cherries during the 1932 season. Cherries grown in France will not be admitted after May 27, except those grown within a small district around Honfleur. Cherries grown in Italy will be admitted until June 5, after which date only those grown in the region of Emilia will be allowed to enter, after June 10, the importation of cherries grown in any part of Italy will be entirely prohibited. Cherries grown in Germany will be admitted until June 26 if accompanied by a certificate of origin, after that date, no German cherries will be admitted except those certified not to have been grown south of lat 53° N or in East Prussia.

#### Important Collections for Harvard Museum

Two great collections have recently been added, according to Science Service, to the Museum of Comparative Zoology at Harvard. John Eliot Thayer has presented his series of thirty thousand specimens of bird skins, forming probably the finest private collection of North American birds. The collection also contains many thousands of nests and eggs. Some of the specimens are very valuable. Extinct birds include the Labrador duck, the Eskimo curlew, and the passenger pigeon. There are ten eggs of the extinct great auk, and several of the California condor, which is becoming very rare. The second collection, bequeathed by Andrew Gray Weeks, contains some 75,000 specimens of butterflies and moths, many being type specimens. The former owner also left to the museum a fund for the care and increase of the collection.

#### Researches from the London Hospital

ANOTHER volume of "Researches", published from the wards and laboratories of the London Hospital

during 1931, has been issued by the Publications Committee, of which Mr Hugh Cairns is honorary secretary. It contains 33 papers, all previously published elsewhere, which range over a wide field in the science and art of medicine. The London Hospital houses a wealth of clinical material, and the staff appears to have made full use of the opportunities for investigation and the publication of adequate records of unusual cases.

#### Ross Institute

THE annual report and accounts for 1931 of the Ross Institute and Hospital for Tropical Diseases, Putney Heath, London, S W 15, shows a serious reduction in contributions in 1931. The Institute at present possesses no endowment fund, and the honorary treasurer, Lord Queenborough, appeals for generous financial support this year. The report also contains a summary of the research work carried out at the Institute, and an account of the results of malaria prevention abroad following measures suggested by the Malaria Department of the Institute.

#### Announcements

PROF C U ARIENS KÄPPERS will deliver the David Ferrier Lecture at the Royal Society on June 2, taking as his subject "Some Correlations between the Brain and the Skull."

THE annual visitation of the Royal Observatory, Greenwich, will be held on Saturday, June 4, and of the National Physical Laboratory on Tuesday, June 28.

DR E F ARMSTRONG (chairman of Council) and Mr J Davidson Pratt (general manager) have been appointed representatives of the Association of British Chemical Manufacturers at the Imperial Conference at Ottawa.

A JOINT discussion on "Vision" has been arranged by the Physical and Optical Societies, to be held at the Imperial College of Science and Technology, South Kensington, S W 7, on Friday, June 3, at 2.30-5.30 P.M. and 7-9.30 P.M. Twenty-eight papers by leading British and foreign contributors have been promised. Visitors will be welcomed, no tickets are required.

It is announced in *Science* that Dr E C Franklin, emeritus professor of organic chemistry at Stanford University, has been awarded the Willard Gibbs Medal for 1932 by the Chicago Section of the American Chemical Society for his "work on liquid ammonia solutions, [which] opened up an entirely new field, and also modified profoundly our views on aqueous solutions. He has made a life-long study, characterised by insight, thoroughness and experimental skill, of reactions in liquid ammonia."

THE National Baby Week Council announces that 'national baby week' will be held this year on July 1-7. It is suggested that, in view of the present economic crisis, the subject of the economic values of maternity and child welfare work should find a place

in local and national propaganda. The report of the Council for 1931 has been issued and gives details of the work accomplished during the year, the competitions organised in connexion with National Baby Week, and awards of the Baby Week challenge shields and prizes.

THE second supplement to the "Bibliography of Bibliographies on Chemistry and Chemical Technology" has been published by the National Research Council of the National Academy of Sciences, Washington, D C, as Bulletin No 86. This publication, which completes those previously issued in 1925 (No 50) and 1929 (No 71), and noticed in *NATURE*, includes references, classified under subjects, of publications, both books and papers, which contain bibliographies of the subjects. It is a valuable and useful work, which deserves to be widely known, and we are glad to direct attention to the issue of a new supplement.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned—A chief veterinary inspector under the Ministry of Agriculture for Northern Ireland—The Secretary, Civil Service Commission, Stormont, Belfast (June 4). An assistant pathologist at the National Hospital, Queen Square—The Secretary, National Hospital, Queen Square, W C 1 (June 4). A principal of the Cambridgeshire Technical School—The Education Secretary, County Hall, Cambridge (June 6). A lecturer in structural and mechanical engineering at the Constantine Technical College, Middlesbrough—The Director of Education, Education Offices, Woodlands Road, Middlesbrough (June 6). A Morna Macleod research student in biochemistry at the Lister Institute of Preventive Medicine—The Secretary, Lister Institute, Chelsea Bridge Road, S W 1 (June 7). A full-time lecturer in mining technology at the Clowin Mining and Technical Institute—The Director of Education, County Education Office, St Mary's Gate, Derby (June 8). A Duddell Scholar of the Institution of Electrical Engineers—The Secretary, Institution of Electrical Engineers, Savoy Place, W C 2 (June 15). A Rhondda Research Student at Gonville and Caius College, Cambridge (open only to students who are residents or sons of residents in Wales or Monmouthshire)—The Master, Gonville and Caius College, Cambridge. A resident lecturer in biology (including gardening) at the Saffron Walden Training College for Women Teachers—The Principal, Training College for Women Teachers, Saffron Walden, Essex. A Leverhulme fellow for fishery research at University College, Hull—The Registrar, University College, Hull. Part-time lecturers in general biology and physiology, respectively, in the Applied Optics Department of the Northampton Polytechnic Institute—The Registrar, Northampton Polytechnic Institute, St John Street, E C 1. A director of the National Institute of Poultry Husbandry, Newport, Shropshire—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

## Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

### Ionisation at High Gas Pressures

IN connexion with papers by Broxon,<sup>1</sup> Tarrant,<sup>2</sup> and Steinke and Schindler<sup>3</sup> on ionisation in pressure chambers, the results of some experiments on the increase of ionisation by  $\gamma$ - and X-rays with rising gas pressure, up to 150-170 atm, may be of interest. By means of a very simple method<sup>4</sup> of determining the ionisation, the relation of ionisation to pressure has been investigated for air. In this method the insulation material is exposed to the same pressure from all sides during the irradiation. The distance between the electrodes in the chambers used was 0.5, 1.0, and 2.0 mm, and the wall of the chamber was made of brass. The radiation was filtered through about 6 mm of brass. A radium preparation of 50 mgm of radium element at a distance of 4.5-12 cm was used. With X-rays, the investigation was made at a constant voltage of 170 kv.

Even the first experiments with  $\gamma$ -rays gave curves for an electrode distance of 0.5 mm (Fig. 1) which showed good agreement with those recently obtained by Broxon (loc. cit.) for the variation with pressure in cases of cosmic radiation. There was a possibility that the ratio between the mean distances between the electrodes (in Broxon's experiments about 130 mm,

about 7000 volts and 500 volts per cm. The field was practically homogeneous, and no after-effects of ionisation (Steinke and Schindler, l.c.) could be found. Separate experiments proved that at the highest pressures full saturation voltage was not reached. When the voltage was reduced to a quarter or a half, however, the drop in the ionisation was only 10-15 per cent. It is extremely unlikely that the agreement between the curves was due to the current being below saturation value if the ionisation follows the same laws as at lower pressures.

It would seem that the observed variation of the ionisation with the pressure could scarcely be explained by the compound effect of the secondary radiation from chamber walls and gas only. The constancy, in particular, of the ionisation at pressures exceeding 100-

FIG. 2—Ionisation-pressure curves for X-radiation

120 atm with  $\gamma$ -radiation cannot be explained in this way. Tarrant (l.c.) has recently obtained similar results with  $\gamma$ -rays from thorium-C'', which also seems to confirm this view.

FIG. 1—Ionisation-pressure curves for  $\gamma$ -radiation

consequently 0.5/130) was by chance approximately the same as that between the mean range of the secondary rays emanating from the chamber walls, which might explain the agreement. Further measurements with electrode distances of 1.0 mm and 2.0 mm, however, gave practically the same curves. In the experiments the field strength varied between

The curves in Fig. 2 were obtained with X-rays for air. Here again the fall in ionisation that is noticeable at high pressures can scarcely be due exclusively to current being below saturation value.

On both curves (Figs. 1 and 2) the points marked by circles were obtained when a reduced electrode voltage difference ( $< \frac{1}{2}$ ) was used.

Possibly the results may be explained by initial recombination of the ions. The probability that an electron after emission will be deflected by the surrounding molecules, in such a manner as to be recombined with the corresponding positive ion, will probably increase rapidly with the gas pressure at high pressures. With softer radiation this effect must be noticeable even at lower pressures. It is also probable that the absolute saturation current cannot be obtained at

high gas pressures, and that as the pressure increases, the current-voltage curves show continuous change over to those prevailing in certain fluids (cf. Jaffé,<sup>5</sup> Stahel<sup>6</sup>).

The results agree well with the similar explanation given by Compton, Bennet, and Stearns<sup>7</sup> in a paper discussing the curve obtained by Broxon.

The investigations are being continued with different gases and different wall materials

### Heterospory and the Angiosperms

FOR many years it has been generally assumed by botanists that in Angiosperms, as in the heterosporous Pteridophytes, the megaspores are larger than the microspores. In a study of megaspore development in *Oenothera rubricalyx* (Gates and Sheffield),<sup>1</sup> it was incidentally discovered that this is not the case. Series of measurements showed that the corresponding absolute values were about  $4930\mu^3$  for the 'megaspore' mother-cell and  $12,630\mu^3$  for the 'microspore' mother-cell at the end of meiosis. The need for comparative measurements of the size of the spores in the pollen and ovules of various plants was pointed out, and brief reference was made to the possible significance of the above condition.

It has since been found that this subject has been independently discussed at some length by Prof R B Thomson,<sup>2</sup> who has also made measurements of spore size in various Pteridophytes, Gymnosperms, and Angiosperms. He finds that in some Cycads, Conifers, and Angiosperms the pollen spore is larger than the seed spore, while in others the reverse is the case.

There is then at present no certainty that the Angiosperms were derived from heterosporous ancestors. That the microspores are larger than the megaspores in *Oenothera*, *Pontederia*, and *Typha*, while they are smaller in *Lilium*, may be a local development in each case. It is to be expected that the morphological and biological relations within the flower, such as size of ovule and length of style, will be factors in adjusting the relative size of the spores which produce respectively the male and female gametophyte. Thus in *Oenothera* the need for a long pollen tube necessitates storage of food material in the pollen mother-cell. This is abundantly present in the cytoplasm and helps to account for the large size of the cell. In the ovule, on the other hand, food storage occurs not in the megaspore mother-cell but especially in the chalazal region of the nucellus.

Thomson proposed the term heterangy for the condition in seed plants where the megaspore is retained within the megasporangium (ovule), confining the term heterospory to those forms in which the megaspores are discharged. Thus the ancestor from which seed-plants (Pteridosperms) arose might have been heterosporous in the sense in which the term is used in *Selaginella* and other Pteridophytes, or it might equally well have been homosporous but heterangious. *Equisetum* well represents an earlier condition, homosporous, homangious, with the gametophytes developing externally to the spores. From such a condition, seed plants showing heterangy and an intrasporal female gametophyte might have developed.

It is well known that although *Equisetum* is homosporous, some of the spores produce a male gametophyte and some a female. The latter may, however, sometimes develop antheridia as well as archegonia, although it does not appear to be known whether the

male gametophyte ever produces archegonia. The fact that the female gametophyte may produce both types of sex organs indicates that the separation of sex tendencies in meiosis in *Equisetum* is not absolute. Hence it would probably be futile to look here for sex chromosomes. Nevertheless, it may be that nuclear differentiation is responsible for the fact that some spores of *Equisetum* produce a male and some a female gametophyte. It needs to be definitely determined whether two spores of each tetrad are male and two female in tendency. If this were so, the differentiation might have resulted from an endosporal chromosome mechanism for sex determination similar in its main features to that which is known in certain Liverworts and in certain dioecious flowering plants, but less fully developed.

It may be pointed out that such a nuclear differentiation of homospores would involve an evolutionary process of quite a different nature from that which has given rise to the differentiated megasporangia and microsporangia of *Selaginella*. It is difficult to see how these two processes could have taken place even successively in the same series of organisms. Thus the heterospory in *Selaginella* could not have been superposed upon the condition found in *Equisetum* if the latter is a case of morphological homospority but with the spores of each tetrad separated as to sex. On the other hand, if the separation of spore types in *Equisetum* is only a partial one, environmentally controlled, it may have been brought about by the same kind of evolutionary process as has produced the differentiation of microspores and megaspores in *Selaginella*.

The differentiation, in the same cone, of microsporangia and megasporangia containing spores which develop their respective gametophytes, as in *Selaginella*, is a somatic differentiation which is completely independent of the meiotic divisions. It could not have been preceded by spore differentiation of a type in which the sex potentialities of the spores in each tetrad are separated. How the condition in *Equisetum* was derived in turn from that in the homosporous leptosporangiate ferns, in which each spore produces a gametophyte bearing both male and female sex organs, we do not know.

Thus it appears that the ancestral seed plants were derived from forms which developed heterangy, but not from homosporous forms with sex potentialities separated in meiosis. Whether they had megaspores and microspores seems quite uncertain. Perhaps descendants of the modern eusporangiate ferns might lay claim to represent such a group. Since, however, the relative sizes of the male and female spores in different families of Angiosperms can vary so widely, there seems no adequate reason at present for denying that the group may have been derived from ancestors which showed heterospory. The sporangium is so closely related to its enclosed spores that differentiation of sporangia as an evolutionary process must be closely connected with differentiation of spores. This means heterospory in the etymological sense, although not necessarily in the sense in which that term is commonly used.

A large and interesting field regarding the relative sizes of the spores in Angiosperms, their evolutionary relationships, and their relations to various features in the biology of the species, here awaits investigation.

## Atomic Weight of Fluorine

WE have recently pointed out<sup>1</sup> that there appears to be no evidence for the view expressed by Prof Moles that methyl fluoride made by Collie's method consists of a constant boiling mixture with methane. It was, however, suggested by Prof Moles that both Collie's critical data and also the compressibility at 0° C (1.011) which we deduced from microbalance measurements are incorrect owing to the above cause. We have accordingly carried out a series of determinations of the critical constants of methyl fluoride prepared both by Collie's method and also by the methyl sulphate-potassium fluoride method used by Prof Moles. We have also measured the compressibility coefficient of methyl fluoride made by the latter method.

The methyl fluoride prepared by Collie's method was that used in our preliminary determinations of the limiting density. The gas generated by the second method appeared to be mixed with rather more than its own volume of methyl ether. The material thus obtained was purified chemically and also by repeated fractionation, the final sample being bubbled through its own liquid. It must be emphasised that whereas it is comparatively easy to obtain pure methyl fluoride by Collie's method, we found it exceedingly difficult to purify the gas obtained by the methyl sulphate method.

The critical data of the two samples of the gas were determined in a modified Andrews compression apparatus. The critical temperatures and pressures were identical for the two samples, whilst the critical volumes agreed within the limit of error of our measurements. This agreement of the results appears to indicate that pure methyl fluoride can be obtained by either method. The critical constants also show no great divergence from those originally determined by Collie. A comparison of the data is given in the accompanying table.

| Observer             | Critical Temp | Critical Press   | Critical Vol     |
|----------------------|---------------|------------------|------------------|
| Collie               | 44.9° C       | 62 atmos         | —                |
| Cawood and Patterson | 44.55° C      | 58.0 ± 0.2 atmos | 3.33 c.c. per gm |

The *pv*-*p* isothermals of methyl fluoride made by the methyl sulphate method were measured in the compression apparatus over pressures of 1 to 3 metres using tubes of 4.5 mm bore. The relationship between *pv* and *p* was linear to a considerable degree of accuracy, and gave at 0° C for the compressibility (1+ $\lambda$ ) over 1 atmosphere the value 1.0115. This result is in satisfactory agreement with the figure 1.011 which we calculated for the compressibility at 0° C from our microbalance experiments at 21° C, and also with the calculations of van Laar when allowance is made for the changes in the critical data. This figure is, however, entirely different from the value 1.018 measured by Moles and Batuecas<sup>2</sup> and used by them in their determination of the limiting density of methyl fluoride. If the compressibility 1.0115 is applied to their normal density a value of 19.2 is obtained for the atomic weight of fluorine. There appears, therefore, to be little doubt that their determinations, both of the normal density as well as of the compressibility of methyl fluoride, are incorrect, though by a partial compensation of errors they lead to an atomic weight of fluorine in accordance with the mass spectrograph measurements.

We have also measured the compressibility of methyl fluoride at 21° C, and find the value 1.0087. This is in satisfactory agreement with our microbalance value of 1.0083, when it is considered that the latter determination was only made over a pressure range of about 170 mm. It will be noted that if we apply the

correct value 1.0087 to our microbalance ratios previously given,<sup>3</sup> the atomic weight of fluorine still remains at the value 19.01.

The details of these investigations will be published elsewhere.

## Ovis astore, a Three-Coated Sheep

INTERESTING speculations have been made in these columns recently on the constitution of the coat of a sheep from Astor (Gilgit) which was first described by Prof Barker<sup>1</sup>.

An examination of the cuticular scale structure of the component fibres of the fleece would afford real evidence as to whether or not such fibres would fall readily into three distinct groups. I therefore obtained, by courtesy of Prof Barker, a sample of the fleece of the sheep from Astor, compared the appearance and lengths of the various fibres, and made a careful examination of the whole of their scale pattern. The scaling of the cuticle was seen by using a method which demonstrates faithfully the scale margins even of densely pigmented fibres.

During a general examination of the sample, I found, in addition to the three classes of fibres

FIG. 1

previously described, namely, long coarse white, short fine white, and short coarse pigmented, two other classes of fibres, these were (a) a long, coarse, and slightly pigmented fibre, (b) a long, curly white fibre intermediate in diameter between the long coarse white fibre and the short fine white wool fibre. It remained to compare the scaling of these five kinds of fibres, and the following results emerged.

I *Heavily pigmented fibres of various lengths* (2.5-5.5 cm). These fibres all showed an irregular segmental mosaic pattern (Fig. 1, A) almost as far as the tip end.

II *Long (6-7 cm) slightly pigmented fibres*. These fibres showed a generalised mosaic pattern (Fig. 1, B) which merged into the irregular segmental mosaic (vide Fig. 1, A) type of scaling, often in the upper portion of the fibre.

III *Long (8-9 cm) coarse white fibres*. This fibre exhibits the generalised mosaic pattern (vide Fig. 1, B) along most of its length, but the irregular segmental mosaic pattern is seen in some portions.

IV *Long (6-7 cm) curly white fibres*, intermediate in diameter between those of III and V (vide infra). The scaling was definitely of a mosaic, and mostly of an irregular segmental mosaic character.

V *Short (1-2 cm) fine curly white wool fibres*. The scales of these fibres were shallow and mostly coronal, that is, each scale generally completely encircled the fibre (Fig. 1, C).

The sample had been cut from the sheep and consequently the scaling of the extreme roots and tips

of fibres could not be observed. From the data given above, however, the following points emerge

- (1) The heavily pigmented fibres (I) vary considerably in length
- (2) The irregular segmental mosaic pattern of the scales of the heavily pigmented fibres (I) is also seen in portions of the long coarse white fibres (III)
- (3) There occurs in the sample a fibre (II) which shows both generalised and irregular segmental mosaic scaling, and in addition is intermediate even so far as pigmentation is concerned, between the fibres under the headings I and III
- (4) A long white fibre is present, intermediate in general appearance between the fine short wool fibre (V) and the coarse white fibre (I), and showing the two mosaic types of scaling

The approximation, therefore, of the scale pattern and other features of all these classes of fibres, suggests that their separation into three constitutional fibre types is hardly possible on the data available. An accurate conception of the constitution of the coat of this sheep can scarcely be gained until further observations are made over a considerable period on the growth and shedding of its constituent fibres

#### Senile Degeneration in Plants

THE question of the 'wearing out' of varieties of cultivated plants that are propagated asexually is a subject of recurring discussion, one of the latest contributions being a paper by Bijhouwer<sup>1</sup>

The classical example is that afforded by the continual replacement of varieties of potatoes by newer varieties, which in their turn seem to lose vigour and disappear from cultivation. But this may be explicable by the tendency of potato stocks to accumulate 'virus' diseases, which will eventually reduce the cropping power of the variety by one-half. Again, the Ribston Pippin apple is often quoted as a variety that has become so liable to canker that it can only profitably be grown on the most favoured soils. But there is evidence that from the time of its general distribution, about a hundred and fifty years ago, Ribston Pippin has been a bad 'doer', retained on account of the outstanding quality of its fruit. So the argument runs on, one school maintaining that varieties not regenerated from seed grow old, while the other argues that the evidence points either to the accumulation of disease or to practical displacement by the introduction of improved varieties. The purpose of this note is merely to direct attention to a most remarkable example, which seems to have escaped notice, of age in a clone only propagated vegetatively.

The saffron crocus (*Crocus sativus* Linn.) has been cultivated on a large scale for a very long time. It is still grown in Spain, Italy, and the Mediterranean countries to yield commercial saffron (the dried stigmas of the flower). It was grown as a crop in the sixteenth and seventeenth centuries between Saffron Walden and Cambridge (*vide* a paper presented by the Hon Charles Howard to the Royal Society in 1678)<sup>2</sup>. Yet the saffron crocus of cultivation is a sterile clone, increasing only by the numerous small offset corms it produces. No wild habitat is known, and though there are several closely related forms from Greece and the Levant which are fertile, none is identical with the true saffron crocus. Its sterility is

reported by all the old writers and is now explicable by its irregular chromosome constitution. But the exceptional feature is the antiquity of the records we possess of the saffron crocus. Not only was saffron as dye and drug familiar to the Greeks, but also in the Temple of Minos, in Crete, Sir Arthur Evans disclosed a beautiful fresco representing a man gathering saffron, the identity of the flowers being unmistakable because of the highly coloured protruding stigmas. The fresco is reproduced in colours in Sir Arthur Evans's "The Temple of Minos", vol 1, p 265. The fresco belongs to the Middle Minoan period, c 1900-1800 B.C., thus giving a recorded history for this clone of more than 3700 years.

#### Feeding Experiments with Methionine

WE have, for some time, been interested in the metabolism of methionine, for which one of us (T. E. W.) has, with Prof. G. Barger, devised a new synthesis<sup>1</sup>. An attempt to find the effect of methionine on growth of rats was actually in progress when R. W. Jackson and R. J. Block<sup>2</sup> announced that methionine, added to a cystine-deficient diet, produced extra growth as compared with controls. As, however, these workers have not yet published figures or experimental details, we consider it worth while reporting our results which confirm their announcement.

The diet we used was that of Sherman and Merrill<sup>3</sup> (using marmite and cod liver oil as sources of vitamins), of which a sufficient supply was mixed in one batch for the whole experiment. To a quarter of this, *l*-cystine was added (2 gm per kilo) and thoroughly mixed in, while to a second quarter *d*-*l*-methionine (2.5 gm per kilo) was similarly added, and the remainder kept for control.

During the control period, which all animals underwent, we adjusted the amount of food supplied so that it was all consumed, but was near the limit of the animals' appetite. Thereafter, both during the remainder of the control period, when only weight measurements were being made, and after transference to cystine or methionine containing diets, this amount of food (8 gm) was supplied to each rat.

The average increase in weight per rat over a period of 25 days was as follows: controls, 16.0 gm; cystine, 27.0 gm; methionine, 22.5 gm. During the preceding control period of 25 days the three groups increased by 12.5 gm, 12.1 gm, and 13.6 gm per rat respectively.

It appears that *d*-*l*-methionine, added to the Sherman-Merrill diet, can produce increased growth in rats, and in this respect it is almost as efficient as cystine. It is curious to find two substances of such different chemical structure acting in the same way, and accordingly we have experiments in progress to determine whether cystine and methionine are interchangeable and utilisable for the same purpose, or whether they are both 'essential' amino acids in which the Sherman-Merrill diet is deficient. We are also comparing the effects of dextro- and levo-methionine.

### A New Kidney Virus

THE discovery of large acidophil intranuclear bodies in the convoluted tubule cells of the kidneys of London sewer rats<sup>1</sup> has led to the examination of rats from other localities in order to determine the prevalence of these structures. The results of this examination have shown that intranuclear bodies are almost invariably present in London sewer rats, including both *Rattus norvegicus* and *Rattus rattus*, but in rats from other localities have been found only in those which presumably might have lived in sewers or fed on town refuse, and have been absent from rats caught in the country under hay-stacks, or in similar localities. Moreover, with two exceptions, they have never been found in white rats, including both normal individuals and others infected with various diseases, or exposed to the action of kidney irritants, such as uranium nitrate. The two exceptions were rats which had been kept with infected sewer rats and may have acquired the infection from them.

It has been found possible to infect white rats by the inoculation of suspensions of the organs of infected wild rats, but the resulting infections have always been slight, never approaching in intensity those shown by the majority of sewer rats in London.

The prevalence of the infection in the latter suggested the possibility that the virus might be present in the sewage, and accordingly white rats were inoculated repeatedly with Berkefeld filtrates of material from the Tyburn main sewer. At first negative results were obtained, but afterwards the sewage was mixed with 10 per cent nutrient broth before being passed through a Berkefeld N filter. Using this method, I have recently succeeded in producing the development of acidophil intranuclear bodies in the convoluted tubules of white rats inoculated with filtrates, and consequently it is evident that the infection is present in the sewage.

With regard to the origin of the virus, it is of interest that similar intranuclear bodies have occasionally been observed in the routine examination of human post-mortem material, but always under conditions which precluded the possibility of any experimental study of the condition. Moreover, I have found them in the kidneys of various species of monkeys dying in public menageries, in which they are very much more common than in monkeys obtained direct from dealers. Although large numbers of other species of animals have been examined, hitherto these kidney virus bodies have been found only in rats and monkeys, apart from the few records of human cases. It is possible, however, that other species may show similar virus bodies in the kidney cells, and I would welcome the opportunity of examining any human or animal tissues which show any abnormalities in the appearance of the nuclei.

### Fatuoid or False Wild Oats

In a recent communication, Mr E. T. Jones<sup>1</sup> has reported some observations on the genetics of a hybrid (presumably triploid) between the tetraploid *Avena barbata* and the diploid *A. brevis*. He argues that, since in his *barbata-brevis* progenies the 'fatuoid' complex breaks up, and since in the *sativa-fatuoid* crosses it does not do so, Huskins'<sup>2</sup> explanation of the fatuoid phenomenon cannot be upheld. His argument appears, however, to contain two fallacies—one genetical and the other cytological.

In the first place, it is almost impossible to interpret the genetical behaviour of a triploid, and particularly of an allotriploid such as this hybrid. This is due to the extreme irregularity of its cytological behaviour and the complications of selection for balance. Jones has apparently neglected this. Moreover, he has assumed that the grain-apex character is linked with, or forms part of, the fatuoid complex, and similarly with respect to the character for awn type. He has advanced no evidence for this assumption, and his observations of "crossing-over" may be nothing more than the result of random assortment of factors carried on non-homologous chromosomes. It may be noted that no crossing-over between factors of the fatuoid complex has been observed by Surface<sup>3</sup> and Philp (unpublished) in crosses between the hexaploids *A. sativa* and *A. fatua*.

In the second place, Jones assumes that pairing of the B and C chromosomes necessarily involves free crossing-over throughout their length. It has generally been assumed on good grounds, however, that like most differences between species, the fatuoid character is determined by a complex of factors. Such differences are usually associated with differences in alignment of genes or in chromosome structure, and are known to reduce crossing-over in the structural hybrid (see Darlington)<sup>4</sup>. It follows, therefore, that a chromosome carrying the fatuoid factors may pair with a chromosome carrying the normal factors and crossing-over may occur, but *not* within the factors of the fatuoid complex where the chromosomes are structurally differentiated.

We may conclude, therefore, (a) that the *barbata-brevis* cross is not analogous with the ordinary fatuoid case, and genetic crossing-over in the fatuoid complex cannot be considered proved, and (b) although crossing-over in the chromosomes carrying the fatuoid and normal complexes occurs, it does not necessarily involve crossing-over in the complex itself and does not invalidate the Winge-Huskins hypothesis.

### Retrocerebral Organ of *Sagitta*

THE recent discovery by Mr C. C. John<sup>1</sup> of the entrance of nerve elements into the anterior end of the retrocerebral organ of *Sagitta* is of much interest. In researches carried out by me<sup>2</sup> no such connexion with nerve cells was seen, though it was stated that there might be a connexion with some of the brain cells near the hind end of the organ, where some spindle-shaped bodies had been described. Mr John's discovery makes this supposition rather more improbable.

Notwithstanding the interest with which I read Mr John's paper, I must take exception to his statement that one of the figures in my memoir (Plate VI, Fig. 45) is misleading. In the course of a discussion on certain features of the nervous system, Mr John emphasises the fact that the optic nerve arises from the central 'punktsubstanz' of the brain and passes back ventral to the retrocerebral organ. With reference to my memoir, Mr John says "his diagram of the brain and retrocerebral organ is apparently misleading. According to him, this organ is completely surrounded by nerve cells, and the optic nerve originates from its posterior border." No mention is made of the next figure of the same plate (Fig. 46), giving a vertical section of the brain, in which the optic nerve

is shown quite clearly as having a course similar to that described by Mr John himself, and he apparently makes the statement quoted solely on an inspection of Fig 45

If, however, he had consulted also my explanation of the figures, he would have seen that this particular figure (Fig 45) is described as a composite one. It is quite true that a single horizontal section would not show all the nerves as depicted in this drawing. An origin for the optic nerve such as is ascribed to me by Mr John certainly could not be a "specific variation", to use his own words.

Sections of the head of a number of different species of Chætonotha were examined in the course of the work for the memoir, and it was found that there was remarkably little variation in the cephalic nerves.

Mr John's work on the hood and coelomic cavities shows that there is need for a careful revision of the development of *Sagitta*, and an interesting, though difficult, piece of research awaits one who can devise a method for keeping and breeding this animal in the laboratory in Great Britain.

### Ciliated Reproductive Bodies in the Cyanophyceæ

A COLLECTION of algæ from a pond near Orpington, Kent, on Feb 6, was found to contain two species of *Oscillatoria* in quantity, among various other forms. The material was cultured in a rather warm laboratory in a large vessel placed near the window, tap-water being added. On Feb 9, a comparatively small, more or less spherical cell was seen to detach itself from the end of one of the filaments of the larger species of *Oscillatoria* (probably *O. limosa* Ag.) and to swim away with the characteristic movement of a ciliated zoospore. The swarmer was blue-green in colour, matching that of the filament but slightly fainter, and showed no definite chromatophore or nucleus. After swimming for some time, it became sluggish in its movements, eventually became stationary, and began to disintegrate about twenty-five minutes after beginning to swim. The next day another similar swarmer was seen to become detached as before. This one was ultimately lost from sight after swimming for about half an hour.

No more cells actually swarming have been observed since, but what are almost certainly stages in the formation of these swarmers have been seen quite frequently in this culture.

The swarmers were naked cells with the pigments apparently mainly or entirely in the peripheral region of the distinctly granular protoplast. It is hoped to publish later a full and illustrated account of this novel method of reproduction.

The presence of swarmers in the Cyanophyceæ has been recorded more than once previously,<sup>1</sup> but none of these records has received universal acceptance. That *Oscillatoria*, a typical cyanophycean genus, may, under certain conditions, produce swarmers, promises to shed an interesting light on the relationships of the class.

### Leaf-Curl of Cotton in Garden Zinnias in North India

IN a note on the leaf-curl of cotton,<sup>1</sup> Mr M A Husan queries the possibility of Aleurodids being responsible for the transmission of this disease, and points out that Aleurodids do not convey it in the Punjab. Since Mr Husan's note was written, Mr Kirkpatrick<sup>2</sup> has definitely proved that the Aleurodid, *Bemisia gossypiperda* of Misra and Lamba, is the vector of leaf-curl of cotton, and recent investigations in Dehra Dun on a virus disease of garden zinnias suggest that it is identical with the leaf-curl of cotton and is transmitted by the same vector. Detailed results will shortly be published. Meanwhile it would seem that the presence of leaf-curl of cotton and its Aleurodid vector in India should be suggestive to those interested in the cotton industry of the country.

### Vibrational Specific Heat of Carbon Dioxide

LAST year I reported on measurements of the velocity of high frequency sound in carbon dioxide at room temperature,<sup>1</sup> the results of which—namely, increasing sound velocity with increase of frequencies from 1 to  $6 \times 10^5$  hz—could be interpreted quantitatively by assuming a definite life-period for oscillation quanta and, resulting from it, an imperfect adjustment of thermal equilibrium in the case of quickly altering conditions, which circumstance is observed as an apparent diminution of vibrational specific heat. Recently Eucken, Mucke, Becker,<sup>2</sup>

FIG 1

and P S H Henry<sup>3</sup> have interpreted similarly the measurements of the vibrational specific heat of diatomic gases, for, if carried out by means of the Lummer-Pringsheim or the sound velocity method, they obtain almost always results lower than those which according to theory may be expected.

The influence of the limited duration of adjustment upon measurements with low frequency sound at different temperatures may be calculated for carbon dioxide by applying the above theory. It should be noted that (1) the symmetric longitudinal oscillations ( $\nu = 1272 \text{ cm}^{-1}$ ) are difficult to excite and therefore of long life-period, (2) the non-symmetric longitudinal oscillations ( $\nu = 2350 \text{ cm}^{-1}$ ) are of strong optical activity, which means emitting their energy

in the form of radiation, their life-period accordingly being much less, (3) different life-periods are co-ordinated with the 1, 2, etc., state of transversal oscillation ( $v = 673 \text{ cm}^{-1}$ )

In this way, without any new assumption, the dependence on temperature of the apparent vibrational specific heat can be calculated as it should result from measuring the velocity of sound at a frequency of  $3000 \text{ sec}^{-1}$ , and a curve (Fig 1) is thus obtained ( $C'$ ), conforming quite satisfactorily to the experimental data at high temperatures especially.<sup>4</sup> In comparison to the normal course ( $C$ ) of the curve, it diverges at high and low temperatures, and approaches it at room temperature. In this way further valuable consequences may be drawn from the work of Dixon, Campbell, and Parker

In these circumstances, the very different interpretations given by Ibbs and Wakeman<sup>5</sup> may be dispensed with. H O KNESER

### Types of Iridescent Clouds

In the winter of 1930-31, I was measuring the height of the aurora in northern Ontario. On one occasion there had been a well-developed single arc which had remained unusually steady throughout the evening, and I was surprised to see at dawn next morning a light band of cloud stretched in a perfect bow from horizon to horizon, and in what seemed to be the exact position that the aurora had occupied. The cloud was of a yellowish, smoky appearance, and quite unlike the cirrus formation present in other parts of the sky. It faded away about sunrise.

The height of the particular auroral arc was not measured, but it cannot have been less than 70 km, and probably was about 100 km. Of course, daylight precluded height measurement of the actual cloud, but if it was connected with the aurora, and therefore likely to have been about the same distance away, the resemblance in apparent curvature would indicate a similar height.

I have seen mention in early writers of similarity between certain cloud-forms and auroræ, but a connexion is hard to explain.

H S WYNNE-EDWARDS  
3515 University Street,  
Montreal, Quebec, April 21

In his account of Prof Størmer's observations on iridescent clouds, Prof S Chapman refers to their rapid internal motion.<sup>1</sup> It is perhaps worth while to put on record that this was also a characteristic of the luminous night clouds of the midsummer of 1885, two years after the Krakatoa eruption. I was living in London at the time, at a house in the City, and obtained from the roof a clear view of the northern horizon at midnight, doubtless the clearer for the mules of built-up area between. The belt of brilliantly white cloud (not iridescent) lying just above the horizon was in rapid internal movement, after turning away one's eyes for a few seconds the forms of component wisps were found to be quite changed. Considering the immense distance (probably 400 miles), the movement must have been very rapid indeed. It is obvious that, to be visible from London at midnight, these luminous night clouds were much

higher than the iridescent clouds, and their height might well have been 80 km.

According to Prof Størmer's observations, no iridescent clouds were visible for many years after 1892. The same seems to have been the case with luminous night clouds, for at midsummer for several years from 1892 I searched for them in vain from vantage points in Essex. But the midnight sky near the horizon was never so clear as it was in 1885, as seen from the heart of London. T S DYMOND

St Leonards-on-Sea,

### Musical Sands

THE various theories referred to by "A T W" in the review—"Nature and Man in Arabia"—published in *Nature* of April 30, have been so frequently and thoroughly criticised and tested since the publication of my first paper in 1888, that one would have thought it unnecessary to revive the discussions now. However, I may point out that after having succeeded in producing musical sand artificially, it was admitted by Crookes, and other leading physicists, that I had proved my explanation of the cause of the sounds to be the correct one.

Some writers, who must have overlooked the details of my work, have disposed of the matter by stating that I ascribe the phenomenon to 'friction' between the grains—which scarcely does justice to my theory. Friction only produces noise in unmusical sands.

Technically, the musical sounds are produced through the rhythmic acceleration of vibrations following abrupt frictional retardation. No other theory can account for the remarkable results that can be experimentally demonstrated with these sands. Unless the grains comply with the necessary physical conditions, no amount of friction will produce musical sounds.

It is scarcely correct to say that the late Lord Curzon, who corresponded with me for some time on the subject,<sup>1</sup> "brought together all known sources of information on the subject."

C CARUS-WILSON

<sup>1</sup> *Nature*, 113, 274, Feb 23, 1924

### The Neutron Hypothesis

DR J CHADWICK's explanation<sup>1</sup> of the mysterious beryllium radiation is very attractive to theoretical physicists. Is it not possible to admit that neutrons play also an important rôle in the building of nuclei, the nuclei electrons being *all* packed in  $\alpha$ -particles or neutrons? The lack of a theory of nuclei makes, of course, this assumption rather uncertain, but perhaps it sounds not so improbable if we remember that the nuclei electrons profoundly change their properties when entering into the nuclei, and lose, so to say, their individuality, for example, their spin and magnetic moment.

The chief point of interest is how far the neutrons can be considered as elementary particles (something like protons or electrons). It is easy to calculate the number of  $\alpha$ -particles, protons, and neutrons for a given nucleus, and form in this way an idea about the momentum of nucleus (assuming for the neutron a moment  $\frac{1}{2}$ ). It is curious that beryllium nuclei do not possess free protons but only  $\alpha$ -particles and neutrons. D IWANENKO

Physico-Technical Institute,  
Leningrad, April 21

*Nature*, 129, 312, Feb 27, 1932

## Research Items

**Concepts of Disease**—Primitive concepts of disease have been studied by Dr Forrest E Clements with special reference to their classification, geographical distribution, and relative antiquity (*University of California Publications in American Archaeology and Ethnology*, vol 32, No 2) Disease is attributed by primitive peoples in the main to five causes: sorcery, breaches of taboo, the intrusion of a disease object, intrusion of a spirit, and loss of the soul. As to sorcery, only very general statements can be made until the distribution of various kinds of sorcery has been studied. The idea of human control over Nature by magical means may be a Magdalenian invention, and its connexion with various forms of sickness an adaptation of the idea to coexisting theories of disease. Breach of taboo is the latest of the concepts, and may have originated independently in middle America, in the Arctic region, and in southern Asia. All occurrences of spirit intrusion are historically connected. It had evidently undergone considerable diffusion before the full neolithic of western Asia. True possession is a differentiation of spirit intrusion and occurs widely in the Old World, though absent from among the more primitive peoples. Soul loss traces to a single Old World origin, possibly in Siberia. Its time of origin seems to have been the upper palaeolithic. All occurrences of the disease object intrusion are historically connected, probably tracing back to an Old World palaeolithic origin. The concept assumes its greatest importance in western North America and in Australia.

**Decorative Motives in Celebes**—Dr Walter Hough has recently made a study of the decorative designs of a collection of ethnographic objects from Central Celebes presented to the United States National Museum by Dr W L Abbott. The motives on the varied examples of bark-cloth are entirely new to the Museum. In an analysis of these designs (*Proc US Nat Mus*, vol 79, art 29), he finds that there are three elements or units, circles, diamonds, and pairs of crescentic figures, diverging outwardly from a base. These are used either in conjunction, sometimes in a definite order, or as units of design approaching the geometrical. It was suspected that the design was zoomorphic, but the clue to its meaning was afforded by certain hooks of horn and wood, used for hanging articles in the house, and from horn spoons. The former illustrate all grades from the conventional to the realistic, the latter are the more conventional. From these it is apparent that the bark-cloth designs are highly conventionalised forms of a representation of a female figure standing between the horns of a buffalo. The buffalo is identified as the Indian *Bos gaur*, and not the small animal *B anoa* with slightly curved horns native to the island, while the female figure can be identified as Durga, the consort of Siva. Thus, although it is not possible to assign a date to the development of the buffalo design, it is obvious that it is subsequent to the introduction of the buffalo and the Siva cult. As this buffalo motive is the exclusive design of Central Celebes, a question arises whether it displaced a previous Nature design. There is no trace of any admixture with an anterior decorative art in this collection.

**Turkey Crosses**—The reciprocal crossing of buff turkeys with the bronze or wild coloured race gives remarkably different results, according to Mr Anthony Lowther, writing in "The Feathered World Year Book" for the present year (p 439). A buff cock mated to bronze hens, it seems, sires chicks resembling young pheasants in colour when in the down,

and ultimately assuming plumage of a light bronze, with the markings usual in a bronze bird. But the chicks from a bronze cock mated to buff hens are silver-grey in the down, and when in full plumage show a new departure in turkey colouring, being grey with irregular bars of buff and bronze. The buff race is also remarkable for the precocious and prolific laying of the hens, which start earlier than other hen turkeys, and often lay a hundred or more eggs in the year, such productiveness in any other individual hen turkeys being regarded as an event worthy of record in the poultry press. In these buff birds, which, as Mr. Lowther remarks, are really decidedly darker than buff, the wing-quills are white, and this constitutes the only approach to pied colouring ever seen in the turkey, which, although showing a fairly wide varietal range of coloration, is never patchy-looking, and altogether seems far more like a wild bird than any other kind of poultry, in spite of having been domesticated by American aborigines for an unknown period before its introduction into Europe.

**Helminthes of the Rat**—M A Tubangui (*Phil J Sci*, vol 46, Dec 1931) has recorded the species of parasitic worms and their incidence observed during the examination of 950 rats (*Mus norvegicus*) which had been trapped in various parts of Manila. The trematodes were represented by three species (one new) of *Euparyphium*, the cestodes by the larval form of *Tænia taeniaformis* (commonly known as *Cysticercus fasciolaris*), by a new species of *Railletina*, and by *Hymenolepis diminuta* and *nana*—the latter species being only seldom met with, the nematodes by eight genera, including *Rictularia*, a new species of which is recorded, and the Acanthocephala by a single species of *Moniliformis*. With the exception of the Trematoda and the new species of *Railletina* and *Rictularia*, all of which are apparently restricted to the Philippines, the worms recorded have been reported also from other countries. It is interesting to note that *Trichinella spiralis* was not found in the rats examined.

**Self-sterility and Crossing in Herbage Plants**—The subject of self- and cross-fertility and the flowering habits of various herbage grasses and legumes is extensively set forth in Series H, No 12, from the Welsh Plant Breeding Station, in a set of fourteen papers by R G Stapledon, T J Jenkin, R D Williams, A R Beddows, and R A Silow. The results of previous observations, as well as new data, have been collected with regard to the rye grasses, timothy, fescues, cocksfoot, red and white clover, etc. In all, 64 species of grasses and 28 of legumes have been investigated. The results are too extensive to summarise here. They range from high self-fertility in *Bromus arvensis* to practically complete self-sterility in red clover. Many grasses, mainly those which are cross-pollinated, are found to produce chlorophyll-deficient seedlings. An interesting study is also made of the swollen, bulb-like basal internodes of the tall oat grass, *Arrhenatherum*. Plants from commercial seed were non-bulbous, while indigenous plants nearly all showed some degree of bulbous development. This was found to be largely independent of soil conditions. The extreme types, when crossed, produced an  $F_1$  which was definitely bulbous. In  $F_2$  and  $F_3$  segregation for degrees of bulb development occurred, but nearly all were more or less bulbous.

**Diagnosis of *Fusarium* Species**—In spite of much work having been carried out on the subject, the diagnosis of species of *Fusarium* in culture is still extremely difficult. As an auxiliary means of

identification, G H Coons and M C Strong have described a method (*Michigan Technical Bulletin*, 115) by which the various species can be diagnosed according to their reaction to growth-inhibiting substances. The identity of an unknown species may either be determined directly if it should be one of the number already investigated and described, or its behaviour compared with that of a known culture. The method is based on the observation that species and varieties of *Fusarium* show marked differences in mycelium colour, ability to change the colour of dyes, and type of growth on media containing aniline dyes, such as malachite green or crystal violet. A large number of species and varieties of the fungus obtained from a uniform mass of inoculum, were grown on a synthetic medium containing the chemical in a graded series of concentrations. Petri dish cultures kept at constant temperature under humid conditions were used. On cataloguing the results, the 54 various species tested were found to fall into groups according to their sensitiveness to, or tolerance of, malachite green, their reaction to crystal violet was used for further separations. It has thus been possible to make out a provisional 'key' for diagnostic purposes based on these responses to the dyes. Repetition of the tests after several years gave the same results, and a study of the morphological features and physiological behaviour of sub-cultures showed that during 10-15 years no significant change had occurred. Besides the triphenylmethane dyes which were chiefly employed, acriflavine and copper sulphate were found to be of possible use as a means of diagnosis.

**An Artificial Humus**—The detailed study of the chemical composition of organic matter in soils has brought out the fact that humus consists largely of two chemical complexes, namely, lignin (40-45 per cent) and proteins (30-35 per cent), with smaller quantities of other substances, especially hemicelluloses, and to a less extent fats and waxes. In spite of the high protein content of humus, its nitrogen is not readily available to the growth of the higher plants, and it has accordingly been suggested that the formation of humus complexes involves the chemical interaction of the proteins with carbohydrate. Arguing that a combination of protein with lignin is especially probable, Waksman and Iyer (*J. Washington Acad. Sci.*, 22, 41, 1932) have found that solutions of protein and of lignin in alkali give, on mixing and neutralising, a precipitate which, when dried and tested, undergoes no more bacterial decomposition than 'humic acid' prepared from peat by alkali extraction and subsequent acid precipitation. In the presence of bases, such as calcium, magnesium, and iron, the preparations become still more similar to 'humic acid' in their physical and biochemical properties and particularly in their high base exchange capacity. The authors, therefore, conclude that the complexes they have synthesised can be considered as the humus-nucleus.

**Thermal Properties of Liquids**—Volume 16 of the *Scientific Papers* of the Institute of Physical and Chemical Research, Tokyo, contains a paper by Mr H. Shiba on the isothermal and adiabatic compressibilities, the specific heats and the thermal conductivities of twenty-nine liquids, all determined by means of the same apparatus. The liquid is contained in a 25 c.c. glass bulb provided with a capillary stem, and the observations of compressibility are made by decreasing the pressure in the stem from 70 cm. of mercury above atmospheric to atmospheric and reading the movement of the meniscus by microscope. The immediate increase of volume of the liquid gives the adiabatic, and the ultimate increase the isothermal compressibility after correction for the com-

pressibility of glass and the decrease of temperature due to the adiabatic expansion. The change of volume of the bulb under pressure was eliminated by surrounding it with a mercury-filled bulb at the same pressure, which was placed in a Dewar flask in a water bath. The compressibilities are of the order  $1 \times 10^{-4}$  per atmosphere, and their ratios of the order 1.3, and as a rule both numbers decrease as the molecular weight increases in a homologous series.

**New Microphone and Loud-Speaker**—In radio-phonics transmission, electrical incision of gramophone records and reproduction given by such records, and in other applications of electro-acoustics, including sound films, the clearness and fidelity of the electro-acoustic reproduction are intimately related to the quality of the transmitting microphone and of the reproducing loud-speaker. In vol. 64 (1931) of the *Rendiconti* of the Reale Istituto Lombardo di Scienze e Lettere, Prof. Giulio Guiletti gives a description of an electrodynamic microphone and loud-speaker which are based on the same principle as the electrodynamic pick-up recently devised by him. The active part consists of a flat rectangular coil of many turns. When this coil is displaced, one side of it cuts normally the induction lines of a uniform magnetic field established between the expanded ends of two vertical bar electromagnets excited by direct current. The coil is kept in position by an elastic support, which allows it to move only in a horizontal plane, and is connected with the transmitting membrane of the microphone and with the reproducing device of the loud-speaker. By this means exact correspondence is obtained, in the microphone between the induction e.m.f. generated in the coil and the displacements of the membrane, and in the loud-speaker between the current and the electrodynamic action operating the reproducer. These correspondences are brought out clearly by simultaneous oscillograms obtained by using the loud-speaker as sound transmitter and the microphone as receiver.

**Heavy Isotope of Hydrogen**—A full account of the work which led to the recognition of a hydrogen isotope with mass 2 (see *NATURE*, Jan. 16, p. 101) appears in the *Physical Review* for April 1. The existence of this had already been suspected for several reasons—in particular, from the difference between the two values for the atomic weight of hydrogen found chemically and from the mass-spectrograph. At the same time, it is present in such small amount, and gives such very feeble displaced Balmer lines, that it is doubtful if the photographic record of these would have been considered completely conclusive if their intensity had not been increased as a result of the fractionation of liquid hydrogen which was carried out, and was expected, on thermodynamical grounds, to increase the concentration of the heavy atoms. It is now stated that the displaced lines are narrower than those of  $H^2$ . No evidence has yet been found from the spectrum that there is an isotope  $H^3$ , but both this and a heavy helium isotope  $He^5$  might be expected to occur from the course of the graph obtained when the number of protons in the nuclei of the elements is plotted against the number of electrons. The work is being continued with an improved fractionating column, but the opinion is expressed that some process of diffusion may have to be used for the final concentrating. Meanwhile, an examination of the enriched hydrogen has been made by W. Bleakney with a mass-spectrograph, which confirms the results of the optical investigation.

**Time Factor in Telephone Transmission**—Until quite recently, the telephone engineer could assume for all practical purposes that speech was transmitted

instantaneously between the ends of telephone circuits, and so he did not need to complicate his problems by taking the time of transmission into account. The introduction of long range telephony and the use of loaded cables have made it necessary to take the time of transmission into account and made the technical problems much more difficult. O. B. Blackwell has now given data of the approximate speed at which signals are transmitted for various kinds of circuit (*Bell Lab Rec*, Jan). When the loading coils (inductance) of the cable circuit are numerous, the speed is about 10,000 miles a second. At a lighter loading the speed is 20,000 miles a second. With unloaded circuits it may be about 180,000 miles a second, and over radio communication circuits it is taken as the velocity of light, namely, 186,000 miles a second. Telephone engineers have found it possible to talk fairly satisfactorily over circuits with time delays as great as 0.7 of a second, but for commercial service a delay of only about a third of that amount is recommended. Another direct effect of the time of transmission on telephone conversation is the distortion of the speech waves due to unequal velocities for different frequencies of the speech components. Still another result of the appreciable times of transmission is the production of echoes caused by the reflection of the electrical energy at points of discontinuity in the circuit. Some of these waves return to the receiver of the talker's telephone and some to the listener's telephone, causing in each case an echo to follow the transmission.

**Conductivity Equation**—The theory of Debye and Huckel as modified by Onsager gives close agreement with the experimental results for the effect of concentration on electrical conductivity at very low con-

centrations, but not for higher concentrations, and must be regarded as a limiting law. It may be written, for a uni-univalent electrolyte, in the form

$$\Lambda = \Lambda_0 - (\alpha\Lambda_0 + \beta)\sqrt{c},$$

where  $\Lambda$ ,  $\Lambda_0$  are the equivalent conductivities at concentration  $c$  and zero concentration respectively, and  $\alpha$  and  $\beta$  are constants for a particular solvent and temperature. This may be written as

$$\Lambda_0 = (\Lambda + \beta\sqrt{c})/(1 - \alpha\sqrt{c})$$

Shedlovsky (*J. Amer. Chem. Soc.*, April 1932) now shows that very good agreement at finite concentrations can be obtained if an empirical term  $Bc$  be subtracted from the second equation,  $B$  being a constant equal to the slope of the plot of  $\Lambda_0$  calculated from the Onsager equation against  $c$ . For many electrolytes  $B$  is very nearly equal to  $\alpha\Lambda_0 + \beta$ . The new equation has the advantage, as compared with other empirical conductivity equations, that it reduces to the Onsager theoretical equation at zero concentration. It holds up to about decinormal in aqueous solutions. The same author, in a second paper, gives new experimental results for the conductivities of sodium, lithium, and potassium chlorides, hydrochloric acid, and potassium and silver nitrates, in the concentration range 0.00003–0.1 normal. These agree with the equation described, except the results with the nitrates, which may exhibit ionic association. In a third paper, in collaboration with MacInnes, he gives measurements of the conductivities of acetic acid and sodium acetate, from which the thermodynamic ionisation constant of the acid at 25° is calculated to be  $1.793 \times 10^{-5}$ , in fair agreement with the values found by Harned and Owen in 1930, and by Harned and Ehlers in the same journal (April 1932), from electromotive force measurements, namely,  $1.754 \times 10^{-5}$ .

### Astronomical Topics

**Astronomical Notes for June**—Venus is nearing the end of its apparition as an evening star, which has been a very favourable one for northern observers. At the beginning of June, one-fifth of the disc is illuminated, this narrows until June 29, when inferior conjunction is reached. Venus is stationary on June 7, and then rapidly approaches the sun.

Jupiter is rather low in the west, but is still observable in the evening. Saturn is observable after midnight, but its south declination of 19° makes observation difficult.

The sun passes the solstice at 3h 25m P.M. on June 21, and summer begins then. Two stars of magnitude 5.2 are occulted by the moon,  $\tau$  Leonis disappears at 9h 22m P.M. on June 11, and 49 Virginis at 8h 47m P.M. on June 13, the times for five fainter stars are given in the "Nautical Almanac".

Three comets, Houghton-Ensor, Carrasco, and Grigg-Skjellerup, are under observation, all are rather faint. Ephemerides for June are given in the May issue of the *Observatory* and in *B. A. A. Journal* No. 7. The R.A. of Grigg-Skjellerup will be about 7 minutes of time less than the ephemeris value, and the declination about 1½° south of it, these large corrections arise from the comet's proximity to the earth, distance on June 7 about 22 million miles.

Add one hour to all times given to express them in Summer Time.

**Nearest Planet to the Earth**—Prof. E. Bianchi obtained an observation of the Reimmuth planet at Milan Observatory as follows

|                          |               |              |      |
|--------------------------|---------------|--------------|------|
|                          | R.A. (1932 0) | S. Decl.     | Mag. |
| May 12d 20h 57m 15s U.T. | 10h 19m 16s   | 9° 10' 48" S | 12.5 |

The distance from the earth was 6.7 millions of miles, according to Dr. Stracke's latest elements. This is

likely to hold the record for many years as the least distance from the earth at which a planet has been observed. Closer approaches of this planet to the earth are, however, possible, the least distance between the orbits being only two million miles. If Stracke's period of 1.639445 years could be taken as exact, there would be an approach at minimum distance in November 1940, but the arc of observation is much too short to make an accurate prediction so far ahead.

The planet would be about nine million miles from the earth at the time of its transits over the sun. It is so small that it is doubtful whether even the largest telescopes would enable it to be seen in transit.

**The Corona in the Eclipse of October 1930**—A Science Service *Bulletin* of April 23 contains an account of a paper read by Prof. S. A. Mitchell before a meeting of the American Philosophical Society at Philadelphia. He gave an account of the results obtained by the expedition to Niuafoou, or "Tin Can Island". A surprising feature was that the corona resembled the type of sunspot minimum, though the minimum is not expected until 1934, he concluded that the coronal minimum type antedated the spot minimum. Dr. W. J. S. Lockyer had announced a similar conclusion in a paper read before the Royal Astronomical Society, but he did not find such a large discordance between the minima, expecting to find the coronal minimum type in the 1932 eclipse. The *Bulletin* also alludes to the spectroscopic results obtained, though these are not given in detail, it is stated that there were formerly some forty lines in the coronal spectrum of which the origin was unknown, but that the results obtained in 1930 left only eighteen lines of unknown origin.

## The Raman Effect and Chemical Structure

IN the May number of *Scientia*, Prof K W F Kohlrausch discusses at some length the significance of the so-called Raman optical effect. The outstanding importance of this phenomenon, which had been foreshadowed by Smekal from theoretical considerations some four and a half years before its actual discovery early in 1928 by Raman, is evident from the unusually large number of publications which have appeared upon the subject.

Experiment has shown that, whereas the valency electrons are stimulated only by high frequency waves, inter-atomic vibrations can be produced by low-frequency radiation, and of the various ways in which such inter-atomic vibrations can be excited, that due to Raman is by far the easiest to carry out experimentally. The apparatus required is the ordinary spectrophotographic outfit. The substances to be investigated, preferably colourless solids or liquids, are intensely illuminated with discontinuous light such as that emitted by a quartz mercury vapour lamp, and the horizontally scattered light is then photographed spectrographically, when, in addition to the usual characteristic lines of the spectrum, weaker satellites are found, the distances of which from the standard lines are a measure of the frequencies of the inter-atomic vibrations. Now, if reasonable assumptions can be made about the forces which are involved, it is clear that most valuable deductions may be drawn about the molecular structure.

It must be remembered, however, that the method has serious limitations, for in many cases the intensity of the lines becomes vanishingly small. Thus comparison of the results with those obtained by the older method of measuring infra-red absorption bands should be carried out wherever possible as controls, since the two methods of investigation are complementary.

The investigation of molecular structure is by no means simple, although some progress has been made. The simplest case is that of the diatomic molecule, since only one kind of vibration is possible and the

Raman spectrum consists of a single line, apart from any lines due to rotation of the molecule and having frequencies of a different order of magnitude. Further, it is recognised that certain uni- or multivalent radicals can be regarded as single atoms for the purpose of calculation. These radicals possess characteristic 'inner' vibrations, which are independent of the 'outer' vibrations of whole radicals within the molecule. Such 'inner' frequencies are in fact constitutive factors and can be determined quantitatively. Thus it is possible to calculate the value of the 'mean restoring force'  $K$  between two carbon atoms which are united by single, double, or triple bonds. Since the values obtained for  $K$  are approximately in the ratio 1 : 2 : 3, it appears that these old-fashioned valency 'bonds' have some mathematical justification, although it is necessary to bear in mind that other factors might influence the attractive force between the atoms. Molecules consisting of more than two atoms or radicals are more difficult to deal with, but even here some progress has been made by grouping some of the atoms into radicals, and also by taking advantage of the fact that the spatial arrangement can often be determined by purely chemical methods.

The usefulness of the method may be illustrated by its application to the much-disputed case of nitric acid and of other isodynamic molecules, such as prussic acid, acetoacetic ester, etc. In the case of nitric acid, the evidence points to the fact that in the anhydrous condition the structure is exclusively  $\text{HO}-\text{NO}_2$ , whereas on the addition of water, some of the molecules undergo change, since the characteristic spectrum of the anion  $\text{NO}_3$  can be detected. Thus the number, position, intensity, and polarisation of the lines in the Raman spectra are determined not only by the spatial arrangement of the atoms within the molecule, but also by the attractive forces between them, and the complete interpretation of these spectra will facilitate a quantitative knowledge of molecular structure, such as has never before been possible.

## Association of Teachers in Technical Institutions

### ANNUAL CONFERENCE

"WE can leave to those who seek them the somewhat Pyrrhic victories over ignorance of a purely academic education with its exaggerated claims to culture, whilst the general body of mankind proceeds to enjoy the conquests won by technical efficiency in producing the necessities of life." That might be said to be the keynote of the first part of the presidential address delivered by Mr S H Moorfield to the Annual Conference of the Association of Teachers in Technical Institutions held in Cardiff during Whitsuntide. Clearly and forcibly he urged the claims of technical education to a foremost position in the educational systems of mankind in what is obviously a rapidly changing world.

In spite of the fact that Hero described the steam turbine about 200 B.C., that Archimedes was credited with the invention of the screw, that Torricelli taught us much of the mechanics of fluids, that Francis Bacon experimented upon the preservation of food by freezing, and that James Watt definitely applied scientific principles to the improvement of the steam engine, technical education as we know it is but some eighty years old. During that period, human achieve-

ment has been amazing. Transport has undergone transformation which may be well called revolutionary. Electricity has been brought to the service of every department of life, and has brought speed, cleanliness, and convenience in its train. Fifty years ago there was no electric motor in industry. Wireless telegraphy and telephony in their present form and with their world-wide range were undreamt of, electric lighting and heating were nothing more than laboratory experiments. Experts in every sphere of life may now catalogue long lists of conquests. In the presence of these vast changes, it is illogical to maintain that the education of mankind should follow the same course that it has followed for centuries. New environment needs a fresh adaptation of the equipment which enables life to be efficiently sustained.

All this is true. Yet, while lip service is paid to the need for a change in educational policy, there remains much to be done "to combat the influence of reactionaries" who still wield so great an influence. "We find them in posts of educational administration, usually products of the older universities, still living

with their feet upon the solid earth of the twentieth century, but with their heads in the mists of the middle ages." As to the old reply that education must be 'liberal', Mr Moorfield was very clear. "Whilst we do not scorn to provide instruction in matters relating to the manual dexterity of the artizan, we emphasise the necessity for the deeper understanding which is provided in a complete technical course designed to meet the needs of those engaged in particular occupations. Such a course is a continuation of a liberal education and cannot in any sense be narrow. Contacts with other occupations are constantly being made, and the engineer begins to understand the miner and the miner the engineer, and the builder will make the acquaintance of both." "We stand for that kind of education which will enable human beings so completely to understand the forces of Nature that the fear of these things, which, in the past, has bred devil-worship, witchcraft, and superstitions in general, may be banished from their lives and cease to burden them with oppression." Further, technical education is "the very spearhead of the attack upon drudgery and want, the fundamental causes of such a large proportion of human unhappiness."

Modern civilisation, however, involves something more than the development of engineering and chemistry and all those departments which come so easily under a scientific heading. They all aim at the successful production which technical efficiency can give. But technical efficiency towards production is not enough. If products be not adequately distributed, their value disappears, and it is in distribution that we find our most pressing problems. Upon the edifice of scientific production we have to impose an equally scientific scheme of distribution. At present the latter is chaotic, and the commercial sides of our great technical institutions are developing schemes of education to remedy the defect. The recent crisis brought to the forefront problems which seem to be baffling even to the expert. There are gluts of wheat, rubber, coffee, tea, iron, copper, tin, and even diamonds. Gold lies uselessly

hoarded in the coffers of two or three of the great nations of the earth. "With plenty in the world, men suffer privation and want." It was in this connexion that Mr Moorfield called for closer liaison between commercial teachers and the general body of technical teachers. Already their function has been laid down in no narrow sense by the Committee on Education for Salesmanship. "Salesmanship as we understand it is a prime function of direction and supreme management. It embraces the study of the fundamental principles of commerce—it is therefore education for commerce on its creative, organising, and executive sides."

Among the resolutions dealt with by the Conference was one urging the closer co-operation of education and industry by means of the formation of a national co-ordinating committee composed of representatives of industry, commerce, educational administration, and technical teachers. Such a committee would be invaluable as a clearing-house for ideas and proposals made by similarly constituted committees which have been formed to act regionally. Another resolution urged the remission of part of the period of apprenticeship for pupils who have followed a full-time course in a technical institution, the extension of opportunity for all entrants into industry to become skilled workers, and the provision of part-time day courses for apprentices and other adolescent workers.

The Conference was officially welcomed by the Lord Mayor of Cardiff and Councillor J Hellyer, deputy chairman of the Education Committee. An exhibition of books and apparatus was held in the Cardiff Technical College. At the annual dinner of the Association on Whit Monday, Prof. George Knox, who has done so much for mining education in South Wales, directed attention to the essentials to industrial success. In addition to capital, raw material, and machinery, suitable personnel to advise upon, organise, and manage these essentials is an absolute necessity. How far, he asked pertinently, has the lack of attention to this matter of personnel contributed to the present position of secondary industries in the South Wales area?

### White Dwarf Stars

THE Halley Lecture delivered at the University of Oxford by Prof. E. A. Milne on May 19 was on the subject of the "White Dwarf Stars." He said that the discovery by Halley of the proper motion of some of the fixed stars led to a remarkable succession of researches in pure astronomy, in modern physics, and in cosmogony generally. The proper motion of one of Halley's stars, Sirius, was found by Bessel not to be uniform, but to contain a periodic element of about fifty years. This led him to suggest that Sirius was in reality double, consisting of a pair of stars, one much fainter than the other. In 1862 a faint star, Sirius B, was actually seen by Alvan Clark close to the place that had been theoretically assigned to the supposed companion. In 1915, W. S. Adams at Mount Wilson Observatory succeeded in obtaining a photograph of the spectrum of Sirius B, which led to the unexpected conclusion that the density of Sirius B was of the order of one ton to the cubic inch. It was shown by Eddington that this surprising density was not physically improbable, and further, that in the light of Einstein's general theory of relativity, the relative displacement of the lines of the spectrum of Sirius A and Sirius B could be estimated. The measurement when actually carried out by Adams in 1925 gave a result so near that of Eddington's estim-

ate that the computed small radius and high density of Sirius B may now be accepted with confidence. A few other stars besides Sirius B are known in which low luminosity and abnormal blueness are combined with high density; these are known as 'white dwarfs'. They are all within five parsecs of the sun, but there is no reason to suppose that this is an abnormal region of space. Consideration of the phenomenon of nova-outbursts and the study of the nuclei of planetary nebulae lead to the conclusion that the list of dense objects can be largely extended. The physical state of matter at these high densities has been elucidated by R. H. Fowler in the light of the researches of Fermi and Dirac. The existence of white dwarf stars shows that it is possible for any gas to exist in either of two states or phases, the 'perfect' or the 'degenerate' phase, the dense state being identified with that of the second phase of a gas. It is suggested that, as foreshadowed by Bessel in regard to Tycho's nova of 1572 the system of Sirius may owe its origin to the nova phenomenon of the original Sirius, two companions resulting, of which one re-expanded and the other remained dense. Bessel's anticipation of the interest of these phenomena in relation to our knowledge of the physical constitution of the universe has been amply justified by the course of events.

### Light-sensitive Cells

A PAPER read before the Royal Society of Arts on April 6 by Dr F H Constable gives an interesting account of light-sensitive cells in the service of man. Such cells may be divided into three classes, (1) photo-conducting cells which change their resistance on exposure to light, (2) photoelectric cells which emit electrons, and (3) photo-voltaic cells which exhibit the Becquerel effect. The last-named are electrolytic cells in which an electromotive force is created when either the electrolyte or an electrode itself is exposed to illumination. To these classes might now be added a fourth, illustrated by the modern cuprous oxide cell, which generates an electromotive force without the presence of an electrolyte. In this type the surface separating the oxide from the supporting copper plate seems to play an important part in the action, and recent theory would indicate the existence of a 'potential wall' at this surface.

After describing various forms which the light-sensitive cells may take, Dr Constable discussed the practical applications of such cells. The intensity of full moonlight measured by a photo-cell is about 0.2 lux, the unit of measurement (lux) being the light intensity 1 metre from a standard candle, while full starlight is of the order of 0.0002 lux in intensity.

One interesting application of the photo-cell is in the measurement of light intensity during the strong illumination of the day and during twilight. Over the period of a year there is very little seasonal variation in the minimum brightness at the time of sunset, while a certain amount of increase in the maximum values is noticeable in the summer and autumn months. It would appear that the principal factor which controls the intensity at dusk is the cloudiness of the sky. Rapidly moving clouds can produce very striking sudden irregularities in the brightness of the sky.

Circuits containing selenium cells may be used for turning lights on or off with the coming on of darkness and dawn. Other interesting applications mentioned are for race timing, apparatus counting, sorting, and burglar alarms. The use of the photo-cell to obtain good synchronisation in talking films is now a well-established practice.

### University and Educational Intelligence

MANCHESTER.—On May 11 the University celebrated the annual Commemoration of Founder's Day by holding a Congregation at which honorary degrees were conferred on Sir James Jeans (Doctor of Science), Dr W D Ross, Lord Rutherford, Sir Arthur Salter, and Mr W R Sickert (Doctors of Laws). The Chancellor, the Earl of Crawford and Balcarres, in his address, alluded to the distinction gained by the University in the award this year of five Royal Society medals, including the Copley medal, to past and present members of the staff. The honorary graduands were presented by Prof J L Stocks, and replies on their behalf were made by Sir James Jeans and Sir Arthur Salter. Sir James Jeans referred to the distinguished roll of physicists produced by the University, while Sir Arthur Salter, in the course of a discussion of the financial crisis, suggested that the discoveries of science are outstripping man's ability to control the powers they offer, and urged that universities ought to aim at producing men capable not merely of academic but also of administrative distinction.

THE Manchester Municipal College of Technology has issued a prospectus of evening courses of lectures

and laboratory work to be held during the summer, commencing May 30. The courses cover various branches of engineering, chemistry and chemical technology, textiles, mathematics, physics, and industrial administration.

THE work of the University of London during 1931-32 is reviewed in the Principal's recent annual report. Growth in the number of students continued steadily both on the internal and external sides, and there was a notable development of university extension work. Candidates for first degrees numbered 3675 and for higher degrees 652, the corresponding figures for the preceding year being 3543 and 548. The reconstitution of the University three years ago made possible an integration which has proceeded apace and proved its quality in vigorous reaction to the stress of hard times. The Court, beforehand in appreciating the need for restraint and encouraged by the Government's determination to continue undiminished the payment of university grants, volunteered to forego during the second half of 1931-32 and the whole of the following year ten per cent of the London County Council's maintenance grants, and to postpone claims on its capital grants so far as possible. In the face of a reduction of grants from the Board of Education and local education authorities for extension courses and adult tutorial classes, the Senate yet contrived to reduce the fees it charges for them. Among the checks to progress suffered in consequence of financial stringency were postponements of the development of the geophysics department of the Imperial College and of the construction of the East London College high voltage laboratory. The most momentous single event of the year was, perhaps, the selection of Mr C Holden as architect of the University buildings to be erected on the Bloomsbury site. A development involving a most important addition to the central institutions of the University is the transformation, to take effect next September, of the London Day Training College, hitherto a municipal institution, into a University department under the title of the Institute of Education.

AWARDS of Commonwealth Fund Fellowships tenable by British graduates in American universities for the two years beginning September 1932 include the following: Mr G C W Allan (Glasgow), to the University of Michigan, in mechanical engineering; Mr K E Boulding (New College, Oxford), to the University of Chicago, in economics; Dr J H Chesters (Sheffield), to the University of Illinois, in metallurgy; Mr K C Dunham (Durham), to Harvard University, in geology; Mr N E G Hill (University College), to Stanford University, in electrical engineering; Mr W A Macfarlane (Balliol College, Oxford), to the University of California, in physical chemistry; Miss M E Metcalfe (University College, Aberystwyth), to Johns Hopkins University, in entomology; Dr J Pace (Liverpool), to Princeton University, in physical chemistry; Mr W C Price (University College, Swansea), to Johns Hopkins University, in physics; Mr A S Roy (St Andrews), to the University of Michigan, in physics; Mr R M Shone, (Liverpool), to the University of Chicago, in business administration; Mr E T Stiller (Glasgow and St Andrews), to the Rockefeller Institute, in biochemistry; Mr George Tatham (University College, London), to Clark University, in geography; Mr D N Truscott (Imperial College of Science and Technology, London), to the Massachusetts Institute of Technology, in electrical engineering. The following have been appointed to Fellowships tenable by candidates from the British Dominions: Mr J H Kirk (Natal University College and Cambridge), to the University of North Carolina,

in social science, Mr A Smithies (Tasmania and Oxford), to Columbia University, in economics. The following have been appointed to Fellowships tenable by candidates holding appointments in government service overseas: Mr D W Dodwell (Indian Civil Service), to Columbia University, in economics, Mr C J Joubert (Department of Agriculture, South Africa), to the University of California, in entomology, Mr W M McNeill (Forest Department, Ceylon), to Yale University, in forestry.

### Calendar of Geographical Exploration

#### May 30, 1580 — The Kara Sea

Arthur Pet, in the *George*, accompanied by Jackman in the *William*, sailed from Harwich to search for the North-east passage. Pet was the first sailor from western Europe to reach the Kara Sea: he separated from Jackman at Vaygatz and the latter and his vessel were lost. On his journey from the Pechora eastwards, he discovered the strait between Vaygatz island and the mainland. Pet's voyage attracted a good deal of interest, and Barents took with him on his last journey a copy of Pet's journal. This was found, along with other books, frozen in among the remains of Barents' wintering on the north-east side of Novaya Zemlya, by the Norwegian walrus hunter, Gundersen.

#### May 31, 1869 — Novaya Zemlya

The Norwegian hunter, E H Johannesen, anchored at Mezhdushar Island, whence he sailed up the west coast of Novaya Zemlya in nearly open water. In the following year he circumnavigated the island. For the latter feat he was awarded a gold medal by the Norwegian Academy of Sciences, he had previously received a silver medal for his hydrographical work in the Kara Sea. His voyages and those of Carlsen and of John Palliser upset all previous theories about the state of the ice to the east of Novaya Zemlya. Carlsen's voyage of 1868-69 was of interest because he found on the north-east coast of Novaya Zemlya in 76° 7' N a house the roof of which had fallen in, and which was filled with gravel and ice. From this frozen gravel were recovered household articles, books, and boxes, preserved perfectly for nearly three hundred years since they were abandoned by Barents in 1597. In 1876 Charles Gardiner, by systematic excavations, discovered many other relics of Barents, including a short account of the most important incidents in the expedition, signed by Barents and Heemskerck. (See also entry for May 30 above.)

#### June 1, 1849 — David Livingstone

David Livingstone set out across the Kalahari desert and discovered Lake Ngami, in 1851, while exploring to the north of this lake, he discovered the Zambezi River, the existence of which in this region was unknown. Before he undertook his next journey, Livingstone studied astronomy in order to make his surveys more accurate. His 1852-56 journey altered completely the conception of the map of Africa. He went up the Liambai, the main Zambezi stream, crossed the Congo basin and reached the west coast at Loanda. Thence he returned to the Zambezi, discovered the Victoria Falls, and followed the river to the east coast, reaching Quilmane in 1856. Thus for the picture of a sandy desert in which rivers lost themselves he substituted a well-watered country, with grassy valleys, much fertile soil and great tracts of forest. He verified Sir R I Murchison's hypothesis that the continent presented an elevated plateau, somewhat depressed in the centre, from the sides of

which rivers flowed to the sea. A journey in 1858 resulted in the discovery of Lake Shirwa, and in the correction of erroneous ideas about Lake Nyasa. In 1866 he reached the southern shores of Lake Tanganyika, of which Burton and Speke had discovered the northern portion, and in 1867-68 discovered Lakes Mweru and Bangweolo. In October 1871 he met H M Stanley at Ujiji and together they explored the north of Lake Tanganyika. Livingstone refused to return with Stanley, he was consumed with eagerness to find the source of the Nile. He reached Lake Bangweolo and died there on April 30, 1830. Livingstone's achievements in African exploration secured his fame, his nobility and humane outlook gained him the warm affection of his countrymen and of the natives among whom he worked.

#### June 1, 1849 — The Great Salt Lake Region

Capt H Stansbury set out from Leavenworth on the Missouri River and discovered a new and shorter route through the Rocky Mountains to Salt Lake City. Stansbury and his assistant, Gunnison, surveyed the deserts to the west of the Great Salt Lake, the coast of the lake itself, and the region between Salt and Utah Lakes. The return journey was made from Fort Bridger, skirting the northern end of the Medicine Bow Mountains and the southern end of the Laramie Mountains to the North Platte River, a saving of about sixty miles. Besides exploring much new ground and making careful surveys, the expedition collected valuable data about the natural history and geology of the region and brought back accounts of life in the Mormon settlements.

#### June 2, 1773 — Ice Pack North of Spitsbergen

Capt C Phipps sailed with two vessels from the Nore and attempted to find a passage through the ice north of Spitsbergen. Their highest latitude was 80° 48' and they reached 20° E, examining the edge of the ice for more than 20° of longitude and finding no opening. Phipps Island was discovered on this voyage. A further exploration of the edge of the ice was made by Buchan and Franklin in 1818, during which they sailed from 10° E to 10° W but could find no opening.

#### June 2, 1910 — North-West Mongolia

D Carruthers set out from Kuzhabar, a village on the Russian frontier, to explore Mongolia. He surveyed the upper basin of the Yenisei River, mapping about 1800 square miles, and filling in many gaps. He then explored the Barkul-Hami district. Carruthers had spent 1908 in the western Tian Shan, south of the Naryn River. In 1909 he had travelled in Arabia, reaching Tema by a route west of El Jauf.

#### June 3, 1870 — Western Borderlands of Arabia

Joseph Halévy, a Jew of French nationality, arrived in Nejrán. This is probably the 'Negrana' of Ælius Gallus, Eparch of Egypt, whose expedition was described by Strabo. From that time until Halévy's journey, no European had visited it. Halévy travelled in the character of a learned rabbi of Jerusalem, and, setting out in 1869, crossed Jabel Yam, the highest ridge of the Yemen, and discovered the ruins of Min. Thereafter he crossed the fringes of the terrible Akháf, suffering much, but finally reaching his goal. He returned to Jauf by a more westerly and less desert route, across valleys on the eastern fringe of the Sachan plateau, in which were many ruins. In spite of the fact that his interests were mainly archaeological, his extensive journey resulted in geographical knowledge of much hitherto entirely unexplored country.

## Societies and Academies

## LONDON

Physical Society, April 15—H E Beckett The measurement of reflection coefficients for radiation at oblique incidence The material is spread upon the metal receiver of a thermopile which, when exposed to radiation, yields an e.m.f. proportional to the absorption coefficient of the surface Results obtained with black and white paints and with polished copper are discussed —W Ewart Williams A new type of interference refractometer The beam from the central part of the collimator objective is divided and each half laterally displaced After passing through the gas tubes, the beams are again reunited so that the interference pattern at the focal plane of the telescope objective is similar to that from a two-plate transmission echelon The brightness of the fringes is approximately twenty times greater than with the usual Rayleigh interferometer, so that the instrument can be combined with a spectrograph for dispersion measurements A new method, based on Benoit's 'fractional part' principle, is developed for this purpose —L G Grimmett A direct reading  $\gamma$ -ray electroscope A dead-beat direct-reading  $\gamma$ -ray electroscope having a linear scale graduated in milligrams of radium is described It is a combination of a special ionisation chamber, Lindemann electrometer, and high resistance, and allows the estimation, in less than three seconds, of the activity of small  $\gamma$ -ray sources of the order 1 mgm radium with an accuracy of 0.5 per cent on a full-scale deflexion

Society of Public Analysts, May 4 —W. R. Schoeller and A R Powell The separation of tantalum, niobium, titanium, and zirconium, and a new analytical grouping The authors' recent method for the separation of titanium from zirconium, based on precipitation of the titania as tannin complex from the nearly neutralised oxalate solution half saturated with ammonium chloride, affords a quantitative separation of tantalum, niobium, and titanium ('acid tannin group') from zirconium, thorium, and aluminium ('basic tannin group') —P S Arup The iodine and thiocyanogen value of Irish butter The iodine value of Irish butter fat rises from May to October and then falls again, owing mainly to the influence of the winter feeding factor The thiocyanogen value (affording a measure of the linolic acid) is higher in winter than in summer, indicating a tendency for the linolic acid to increase as the oleic acid decreases The proportion of linolic acid in the unsaturated fatty acids in Irish and foreign butters ranged from 9.1 to 13.2 per cent —C Ainsworth Mitchell and T J Ward Sediments in ink and in writing Among the external causes producing sediments recognisable in writing are alkali in glass, moulds, and extraneous substances such as dust, vegetable debris, and starch A new method of detecting oxidase in moulds, etc., has been based on the acceleration of the oxidation of a solution of tannin and ferrous sulphate by the substance containing the oxidase, the resulting precipitate of basic ferric tannate being collected and weighed —L G Haddock and Norman Evers The determination of minute amounts of copper in the presence of iron and certain other metals The separation of copper from iron by means of ammonia or hydrogen sulphide is incomplete An accurate method consists in keeping the ferric iron in solution by addition of citric acid and ammonia, adding sodium diethylthiocarbamate (Callan and Henderson), extracting the solution with carbon tetrachloride (Grindel), and measuring the colour of the extract in a tintometer, or comparing it with standards

containing known amounts of copper So little as 0.005 mgm of copper may be detected in the presence of 0.25 gm of iron

Royal Meteorological Society, May 18 —G Bransby Williams The rainfall of Assam Assam is the wettest province of the Indian Empire, and contains Cherrapunji (where the mean annual rainfall is 460 in.), reputed to be the wettest place in the world The period of the south-west monsoon is of greater length in Assam and Burma than in north and central India In consequence there is a marked difference between the seasonal distribution of the rainfall in these countries On an average, in the Central Provinces 87.6 per cent of the year's rain falls in the four months June to September, whereas in Assam only 65.9 per cent falls during these months The chance is 400 to 1 against the rainfall at any station in Assam in any one year being below 50 per cent of the mean —J Wishart On the secular variation of rainfall at Rothamsted A detailed study of the rainfall at Rothamsted over the 76 harvest years, 1854–1929, shows that the maximum in autumn (and equally the minimum in spring) occurs significantly later to-day than was the case 76 years ago, but there is some sign that this movement is now reversing its direction, as appeared to have happened towards the end of the eighteenth and again in the middle of the nineteenth centuries, as judged from early records at a number of other stations —C E P Brooks and Theresa M Hunt The zonal distribution of rainfall over the earth The mean annual rainfall in each five-degree zone was calculated separately for the land and sea areas by a planimetric method, using the best available rainfall charts for each country or ocean The results show maxima over the land in latitude  $0^{\circ}$ – $5^{\circ}$  S and  $50^{\circ}$ – $60^{\circ}$  S, a minimum in latitude  $30^{\circ}$  S, over the sea, maxima in  $50^{\circ}$  N,  $0^{\circ}$ – $10^{\circ}$  N, and  $40^{\circ}$ – $45^{\circ}$  S, minima in  $40^{\circ}$ – $50^{\circ}$  N,  $20^{\circ}$ – $30^{\circ}$  N, and  $20^{\circ}$  S

## EDINBURGH

Royal Society, March 7 —N A Mackintosh Research on whales in the Antarctic (lecture) Observations have shown no racial distinctions between the whales of South Georgia and South Africa, but considerable differences exist in the make-up of the local whale populations There is a definite breeding season in the winter, and the young are born in the following year Sexual maturity is reached about two years after birth The high proportion of immature whales killed is prejudicial to the stock and to the whaling industry itself The work of the *Discovery*, the *William Scoresby*, and the *Discovery II* has been concerned mainly with the whales' environment in the Atlantic sector of the Southern Ocean The main currents and water masses have been measured and charted, and the circulation of the nutrient salts determined Detailed investigations have been made on the plankton *Euphausia superba*, the food of whales, is widely distributed, but its northern limit is usually defined by the  $3^{\circ}$  isotherm

## PARIS

Academy of Sciences, April 11 —Paul Montel A formula of Darboux —Michel Fekete The changes of sign of a function in the interval  $0, \infty$  —Miron Nicolesco The extension of a theorem of F Riesz to subharmonic functions of order  $p$  —S K Jaremba The differential equations corresponding to surfaces of genus one —D Riabouchinsky The movement of an incompressible fluid round an obstacle —Basile Demtchenko The slow movements of compressible fluids —Georges Durand The determination of the

velocity due to indefinite rows of vortices —J Thibaud, J J Trillat, and Th v Hirsch Researches on the polarisation of a bundle of electrons by crystalline reflection The experiments described and illustrated leave the question of the existence of polarisation doubtful —Dinca Samuracas The influence of the magnetic field on crystallisation The magnetic field changes the direction of the currents in the liquid due to changes in concentration It is shown by experiment that crystallisation can be affected by a magnetic field —Constantin Salceanu The influence of substitutions on the magnetic rotation and double refraction of naphthalene derivatives, the comparison of the rotatory dispersions and magnetic double refraction —Mme Irène Curie and F Joliot The nature of the penetrating radiation excited in light nuclei by the  $\alpha$ -particles The experiments described support the hypothesis of the neutron of mass 1 and charge 0 The nuclei of beryllium irradiated with the  $\alpha$ -rays of polonium emit a complex radiation including a  $\gamma$ -radiation emitted approximately equally in all directions and a very penetrating radiation (1 cm of lead absorbs about 6 per cent) emitted unsymmetrically with respect to the direction of the incident  $\alpha$ -particles —Mme P Curie and S Rosenblum The fine structure of the magnetic spectrum of the  $\alpha$ -rays of radioactinium The large electromagnet of the Academy of Sciences was utilised in these experiments The results of the measurements of eight lines are given —G Mano The slowing down of the  $\alpha$ -rays of thorium-C' in air —A Portevin, E Prétet, and H Jolivet Structural hardening by heating the iron-nickel-tungsten alloys —F Bourion and E Rouyer The cryoscopic study of ether and acetone in water and in solutions of sodium chloride —Marcel Boil Chemical kinetics in receivers surrounded with a great thickness of mercury Comparative measurements of the hydrolysis of tetrachloroplatinic acid in the dark and surrounded by 10 cm of mercury showed that the velocity constant of the reaction in the latter case was one-sixth that in the former The cosmic rays are suggested as affording a possible explanation —D Rosenthal and M Mathieu Mild steel welds made with the electric arc Effect of coated electrodes from the point of view of distortion of the crystalline grains —Jean Bouchard The photosensitising action of colourless fluorescent materials on the flocculation of colloidal solutions Solutions of colloidal arsenic sulphide to which various colourless fluorescent substances were added were exposed to ultra-violet light In each case there was a marked acceleration of flocculation —Ed and R Chauvenet The formation of compounds in aqueous solution of thoryl chloride and alkaline chlorides The thermochemical method pointed to the formation of molecular compounds of the type  $\text{ThOCl}_2 \cdot \text{MCl}$  The caesium and potassium compounds were isolated in crystalline form —Raymond Delaby The vinylaryl and vinylalkyl carbinols their transformation into  $\beta$ -homoacroleins —André Meyer and Robert Vittenet The preparation of homophthalic acid by the oxidation of indene Homophthalic acid can be prepared with 66 per cent yield by the oxidation of indene with potassium bichromate and sulphuric acid in the proportions given —P Russo The position of the northern border of the Morocco Meseta L Dubertret, A Keller, and H Vautrin Contribution to the geology of the Djezireh (Syrian territory on the left bank of the Euphrates) —Paul Chauchard The factors of variation of the reducing power of sea water —A Guillermond Cytological observations on the Rhodothobacteria —Th Savulescu and T Rayss The influence of external conditions on the development of *Negrospora Oryzae*, a parasite of maize in Roumania —R Bonnardel and W Liberson Re-

searches on the physiology of human work at high altitudes Comparative study of metabolism, cardiac frequency, and mental fatigue at Paris and the physiological laboratory on the Jungfrauoch (3457 metres) Raoul Lecoq The rôle of the B vitamins and of the food equilibrium in the utilisation of the proteins —L Genevois and Tamara Nicolaieff The prevention of bacterial lactic fermentation by the  $\alpha$ -halogen substituted fatty acids —H Bierry Specificity and chemical structure —Georges Defandre *Litharchaeocystis costata*, a marine fossil Chrysophyceae. Remarks on the Chrysostomataceae —C Levaditi and N Constantinesco The penetration of the syphilitic virus in spontaneous neoplasms and lymphadenoma, in mice —P Lépine and J. Caminopetros The action of the serum of patients cured of exanthematic typhus and of *fièvre boutonneuse* on the exanthematic virus of Athens rats —A Leulier, B Pommé, and A. Richard Potassium and chronaxy in experimental muscular degenerescence

## ROME

Royal National Academy of the Lincei, Dec 20 —G Armellini and G Conti Investigations on the variations of atmospheric absorption and various observations At Rome, atmospheric absorption is slightly less in winter than in summer, but the difference does not seem to exceed 25 per cent Observations on planets, and on the position of Uranus during its conjunction with  $\alpha$  Piscium, are recorded —T Boggio Fresnel's wave-surface —G Lampariello Levi-Civita's differential equations in the problem of liquid jets. Levi-Civita has recently treated analytically the problem of liquid jets of the very small thickness compared with the length when the internal pressure in the neighbourhood of the orifice remains sensibly above the atmospheric pressure The application to this system of the general theorem of existence and unicity is now considered —G Gallina Homogeneous functions —M Crenna Ribaucour's deformable congruences —M Manarini A theorem of Staude-Wan der Woude relating to the motion of a heavy body about a fixed point When a heavy body is suspended at a fixed point  $O$ , there exist an infinite number of straight lines through  $O$  which form a quadric cone (Staude's cone) and are, for the body, axes of permanent uniform rotation with suitable angular velocity Wan der Woude showed that such a cone is formed of those straight lines through  $O$  which are principal axes of inertia with respect to one of their points It is now shown that these propositions may be simply derived and completed by deducing, for the duration of a whole permanent rotation, a formula identical with that of Galileo for the simple pendulum —G Piccardi Molecular spectra and spectroscopic analysis (1) In spectra containing large numbers of lines, identification of an element is often difficult or uncertain In such cases, more valuable information may be obtained by using less powerful means of excitation and examining the band spectra produced —A Rossi and G Scoz Presence of an acid-soluble organic phosphorus compound in the sub-maxillary gland of the dog This gland contains about 140 mgm of phosphorus per 100 gm of the dry tissue, about 40 mgm. of the phosphorus being in the form of an acid-soluble compound Part at least of the latter is determinable only after incubation of the acid extract at  $37^\circ$ , this indicating a labile organic phosphorus compound of behaviour resembling Eggleton's phosphagen —G Scoz Investigations on cystine metabolism Experiments on rats and puppies show that cystine exerts a favourable influence on the general bodily growth and on the growth of the hair

## Forthcoming Events

## FRIDAY, MAY 27

- LONDON SCHOOL OF ECONOMICS, at 5—Prof L Hogben  
The Biological Premises of Historical Interpretation  
(Lecture)
- ROYAL ANTHROPOLOGICAL INSTITUTE (Human Biology  
Research Committee), at 5 30—Discussion on the  
Standardisation of Anthropometric Method
- BIRKBECK COLLEGE, at 6—Dr H J W Hetherington  
Theory and Practice (Haldane Memorial Lecture)
- ROYAL SOCIETY OF MEDICINE (Epidemiology and State  
Medicine Section) (Annual General Meeting), at 8—Sir  
Aldo Castellani The Epidemiology of Some Typical  
Mycoses
- ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir Walter  
Morley Fletcher New Conceptions of Medical Research

## SATURDAY, MAY 28

- NORMAN LOCKYER OBSERVATORY (Salcombe Regis, Sid-  
mouth), at 3 30—Opening by Sir Frank Dyson of the  
'Mond' Photographic Equatorial and Dome Other  
speakers Sir Richard Gregory, Bart, Dr R L Mond,  
and others
- ROYAL SOCIETY OF MEDICINE (Physical Medicine Section)  
(at Alton)—Annual Summer Meeting

## MONDAY, MAY 30

- INSTITUTION OF ELECTRICAL ENGINEERS (Summer Meeting  
at North Midland Centre) (*continued on May 31 to  
June 3*)

## TUESDAY, MAY 31

- INTERNATIONAL NEUROLOGICAL CONGRESS (at Paris) (*con-  
tinued on June 1*)

## WEDNESDAY, JUNE 1

- OXFORD UNIVERSITY (in Sheldonian Theatre), at 12 noon  
—Lord Moynihan The Advance of Medicine (Romanes  
Lecture)
- ROYAL SOCIETY OF MEDICINE (Surgery Section) (at General  
Infirmary, Leeds)—Annual Provincial Meeting

## JUNE 1 TO 4

- SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES (Congress  
at the Civil Service Commission, Burlington Gardens,  
W 1)

Dr R E Mortimer Wheeler Field Archaeology in  
Great Britain (Presidential Address)

Dr W E St L Finny Medieval Games and Gader-  
ings (Presidential Address to Archaeology Section)

J Ramsbottom Fungi as Scavengers (Presidential  
Address to Botany Section)

Prof H L Hawkins The Structure of the South-  
East of England (Presidential Address to Geology  
Section)

H Main The Camera as a Naturalist's Recorder  
(Presidential Address to Zoology Section)

G L Pepler Town and Country Planning (Presidential  
Address to Regional Survey Section)

Sir Arthur Thomson The Drama of Animal Life  
(Evening Lecture)

Capt G Dollman Great Game Animals of Africa  
(Evening Lecture)

- NEWCOMEN SOCIETY (Summer Meeting in N E Stafford-  
shire)

- INSTITUTE OF TRANSPORT (Congress at Buxton)

## THURSDAY, JUNE 2

- ROYAL SOCIETY, at 4 30—Prof C U Ariens Kappers  
Some Correlations between the Brain and the Skull  
(David Ferrier Lecture)

- ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr  
J W McNee The Liver and Spleen their Clinical  
and Pathological Associations (Croonian Lectures) (1)

## FRIDAY, JUNE 3

- PHYSICAL SOCIETY OF LONDON AND OPTICAL SOCIETY (at  
Imperial College of Science and Technology), 2 30 to  
5 30, and 7 to 9 30—Joint Discussion on Vision

No 3265, VOL 129]

- ROYAL SOCIETY OF MEDICINE (Disease in Children Section),  
at 5 30—Annual General Meeting
- ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof J C  
McLennan Electrical Conductivity of Metals at the  
Lowest Temperatures

## SATURDAY, JUNE 4

- ROYAL OBSERVATORY, GREENWICH, at 3 30—Annual  
Visitation
- INSTITUTION OF ELECTRICAL ENGINEERS (London Students'  
Section)—Summer Outing to Southampton

## Chemical Warfare and Disarmament

ADDRESSING the House of Commons on May 13 on disarmament, Sir John Simon, Secretary for Foreign Affairs, said that everyone would agree it was desirable to enter into an agreement, and make effective its observance, against the use of poison gas in warfare. It was an example of 'qualitative' disarmament, contrasted with 'quantitative' disarmament, aiming at a limitation of the number and size of ships and the calibre of guns. Sir John Simon's declaration was received with cheers, and his argument was reinforced in the debate by Mr Winston Churchill, who laid stress on the indiscriminate character of gas warfare, entailing death and wounds not merely to combatants but also to the civil population, men, women, and children, far removed from the area of hostilities. He pointed out that the acceptance among the leading authorities of different countries of the bombing of open towns would introduce a new idea into warfare, "an idea not compatible with any civilised decency". Are we to allow ourselves to be led, step by step, into contemplating such hideous episodes as part of the ordinary give and take of war?

The question is one with which our chemists—and by the same token our physicists and bacteriologists—who create in their laboratories the raw material, *fabrika fabris*, for scientific warfare, are directly concerned, a question which has caused searchings of hearts and consciences, not resolved by ordinary appeals to patriotism. Dr Delisle Burns's letter published this week in our correspondence columns affords evidence of these misgivings. But it is safe to say that men of science as a whole would not approve of any limitation of the scope and character of scientific research into poisons or any other branch of science which may find application in warfare. No Pope of Geneva must be allowed to compile an *index expurgatorius* for men of science. "Why, sir," said Dr Johnson, "that knowledge may, in some cases, produce unhappiness, I allow. But, upon the whole, knowledge, *per se*, is certainly an object which every man would wish to attain." Moreover, as Major Lefebure points out in "The Riddle of the Rhine", if every chemist in the world became a pronounced pacifist, new chemical warfare substances would undoubtedly arise as a normal outcome of research.

It is well to know, however, that the question of disarmament is being studied in all its aspects, officially and unofficially. The report of the Inter-Parliamentary Union on "What will be the Character of a New War?" (P S King and Son) includes

No 3266, Vol 129]

a section on chemical and bacteriological warfare, by Dr Gertrud Woker, of Switzerland, setting out the general preparations for war, expert views on the effects of chemical warfare, the medical effects of poison gas, and protection of the civilian population. Reference is made to the Report of the American Government on the proposals of the Mixed Committee of the Preparatory Disarmament Commission, in which the view is expressed that the absolute prohibition of training men in the use of chemical weapons in the widest sense would put an end to chemical and medical studies and research, so that such a measure could not possibly be put into practice. In 1924-25, the United States budgeted for an expenditure of 8,700,000 dollars on chemical defence measures. The great chemical industries, that country asserts, are bound together by their common capital and collaborate to supply each State, under the auspices of the military authorities, with the materials for national defence should the need arise.

Retaliation over enemy territory appears at present to be the only effective defence against chemical warfare in its application to cities. Arming the whole civilian population with masks is, according to one expert, "unthinkable". The provision of ventilated underground refuges is also impracticable. Air manœuvres over London have proved incontrovertibly we are told, that in the case of serious attack, a great part of London would be destroyed. Of 250 aeroplanes taking part in a night attack, only sixteen were discovered by searchlights. Prof Langevin has come to much the same conclusion in regard to Paris. He estimates that 100 aeroplanes, each carrying a ton of gas, could in an hour cover Paris with a gas cloud 20 metres thick, and if there were no wind, Paris would be annihilated. Prof Noel Baker in his book "Disarmament" (1926) says that the "Berlin bombs" prepared for use in the 1919 campaign would have killed every person in the open within 600 to 800 metres of the spot where the bombs exploded.

Progress is continually being made not only in the potency of chemical poisons but also in the art of mixing poisons to produce desired effects. Chlorine, the first gas used, is now superseded because its action is too sudden and its presence in the atmosphere too obvious. Mustard gas, used in the production of indigo, still retains its evil pre-eminence, for no method of counteracting some of its effects has been discovered. Dr Gertrud Woker concludes her report with a statement that, as things stand at present, war mania

would aim only at the complete and unscrupulous destruction of the enemy. "How long", she asks, "is the flower of each nation, and even every nation as a whole, to be sacrificed to this Moloch?"

Is the picture as black as painted? Is the gloom as unrelieved as even Sir John Simon—for whose *aequanimitas* in these difficult times the nation has every reason to be grateful—would have us believe? For an answer we may turn to an article by James E. Mills on chemical warfare in the April issue of *Foreign Affairs*, a quarterly review published by the American Council for Foreign Relations. In reality, he says, the propaganda against it notwithstanding, gas is the most humane weapon existing to-day in actual warfare. He proves by statistics that the proportion of deaths resulting from gas is far below the general proportion, as 2 per cent to 24 per cent in the case of American casualties. Gas does not mutilate, and it seldom causes extreme pain, those gases which poison without pain being preferred. Its use can be controlled, for example, tear gas will disperse a mob without fatalities unavoidable by the use of machine guns. It is a relatively cheap weapon, and thus makes for equality between large and small nations. "It is possible to assert", he claims, "that the new and powerful weapons of war made possible by science may be a gain to the world." Gas warfare is particularly powerful as a defensive weapon, for reasons which will be obvious. He thinks the dangers of attacks on cities are over-estimated. *Omne ignotum pro magnifico!*

Research on new poisonous compounds cannot be limited, for they play a necessary part in the development of insecticides, fungicides, germicides, disinfectants, preservatives, fumigants, and drugs. It has been estimated that the destruction caused by insect and animal pests in the United States reaches the astonishing total of more than two billion dollars a year. The bubonic plague in India alone cost 8,000,000 lives in the first ten years of this century. As becomes a writer who is able to discuss a question in a scientific spirit, Mr Mills concludes his article with a constructive suggestion. Whether a nation at war under present conditions would drench with poison gas the great cities of an enemy country, with the full knowledge that retaliation would follow, may be left an open question. No objection should be taken, he suggests, to the use of tear gas in war, owing to its non-fatal character. So far as protection can be afforded by treaty, he thinks that the use of poison gas should be allowed only in a nation's own territory as a means of defence. In this way, civilian

populations would be protected, if treaties were observed

Disarmament must be studied scientifically—coldly and dispassionately, without “laziness, haziness, craziness”, *surtout* without any trace of hysteria. Dr Cyril Norwood, headmaster of Harrow, in his presidential address last January to the Science Masters’ Association, appealed to “scientists” to create a community “which will put spell-binders and slogan-manufacturers of modern politics and journalism out of commission”. We are gratified that our own scientific men, with knowledge and experience, have made contributions to the discussion of disarmament satisfying these criteria. Particularly we would cite Major Victor Lefebure’s “Scientific Disarmament a Treatise on the Facts of Armament”, reviewed in *NATURE* of April 4, 1931. Our reviewer sounded a note which finds an echo in the present article. “Our failure to grapple with the facts of disarmament”, he wrote, “still allows politicians to find an easy refuge in moral and economic platitudes”. Disarmament, as Major Lefebure insists, is a technical matter, requiring close and continuous study by scientific methods, especially to secure the extension of the ‘conversion lag’ between the issue of war and the exploitation of the vast resources placed at the disposal of the combatants by science and industry. Science has discovered the poison it will discover the antidote.

Let us continue our journey, holding the dim taper put into our hands, singing songs of comfort as we go along. May it light us to a world where there shall be no more war between nations—and between people living in the same street! Spell-binders, slogan-manufacturers, schoolmen, babbling sophists merely inspissate the gloom.

### W. H. Dines's Scientific Papers

*Collected Scientific Papers of William Henry Dines, B.A., F.R.S.* Pp. x + 461 (London: Royal Meteorological Society, 1931) 15s. net

THE Royal Meteorological Society is to be congratulated on its decision to reprint the scientific papers of Mr W. H. Dines as a memorial to that eminent meteorologist. The book, which has now appeared, fulfils its purpose admirably and is a credit to the Society as well as an honour to one of its most distinguished fellows. England owes a great deal to its band of amateur men of science, and meteorology probably owes more to the amateur than any other of the major branches of science. Mr W. H. Dines was an amateur in the best sense

of the word. He took up meteorology because it made its own appeal to him, no doubt influenced to some extent by the meteorological work of his distinguished father, Mr George Dines. This compilation of his papers brings home to the reader what a large part Dines played in the development of scientific meteorology in Great Britain, but it also helps those of us who knew the man and read each one of his papers as it appeared to see his work as a whole, and to judge how much of it will be of permanent value and how much of it was laying the foundations on which others have built. It is probably in the last respect that Dines made his greatest contribution to science. Throughout his scientific life Dines was a pioneer, he had the instincts of a pioneer, and the methods of a pioneer. His tools were always of the crudest, without any refinement and without any unnecessary accuracy, but capable of doing the job for which they were designed.

Dines’s method of measuring wind pressure by the use of a rotating arm driven by an old second-hand steam engine in the open air will appear crude in the extreme to the worker in a modern aerodynamic laboratory with its wind tunnels and delicate balances, but his method of eliminating the velocity by balancing the wind pressure on the plate against the centrifugal force, both of which depend on the square of the velocity, was a stroke of genius. With this crude apparatus Dines provided data of the wind pressure on plates of different sizes and shapes which were used by engineers and meteorologists until the advent of aviation raised aerodynamics to a separate science. The nine papers on anemometry which form the main part of Section I of the book are valuable records of the first steps in this new science, although they had all been written before aviation had appeared on the scene as a practical proposition. Most of them, naturally, have now only a historical interest, but it would be well if the younger workers in our aerodynamic laboratories would read them to see what can be done without elaborate instruments.

Towards the end of the nineteenth century meteorologists on the Continent and in America had commenced to investigate the upper atmosphere by means of balloons and kites, but no work was being done in the British Isles. This was largely due to the want of money, for the instruments were expensive and many were lost. This was an unknown country which had a great attraction for Dines’s pioneering spirit. He took up kite-flying with great energy. The kites used on the Continent were expensive, fragile structures, so he devised his own kites, which were inexpensive.

and by comparison unbreakable—in any case, it cost little to repair them. He built a winding gear which was a marvel of ingenuity but which caused engineers to smile. He bought another steam engine (Dines loved a steam engine, especially the one which sometimes drove his motor-car) to drive the winding gear, and above all, he designed a meteorograph recording pressure, temperature, humidity, and wind which cost less than a tenth of the instruments used in Germany and America. Later on, when the discovery of the stratosphere shifted interest from the lower to the upper atmosphere, he abandoned kites for balloons. Here again he developed an instrument of which the chief characteristic was cheapness combined with sufficient accuracy.

With these simple and inexpensive instruments Dines carried out the work which forms Section II of the collected papers. The early experiments and instruments are fully described, and a series of papers gives the results obtained, first with kites and then with balloons. Finally, the whole work is summed up in a paper entitled "The Characteristics of the Free Atmosphere", published in 1919, which is still the chief source of our information about the upper atmosphere over the British Isles.

In 1922, Mr. Dines passed on his work on the upper atmosphere to his son, L. H. G. Dines, who is still in charge of this work at Kew Observatory. But Dines could not give up his interest in meteorology, it was only transferred, and this time to another branch which was sadly in need of a pioneer. A great deal of work had been done for a number of years by many eminent men on the part played by radiation in the distribution of heat in the atmosphere, but it cannot be said that they had got very far. It is a difficult subject and one requiring a whole army of pioneers to blaze a way through a very forest of physical difficulties. The third section of the book is devoted to papers describing his work on radiation, which commenced in 1917 and continued to the time of his death. The characteristics of this section are similar to those of the two already described: the approach to a difficult and almost unexplored subject, the design of instruments, the record of careful observation, and a valuable discussion of the results obtained. This work is also being continued at Kew Observatory.

The final section of the book deals with a number of miscellaneous papers, the chief of which is, probably, an address delivered before the Sanitary Institute so long ago as 1895, which received much public attention at the time because of his insistence

on the necessity for a low temperature and fresh air if health is to be preserved.

In order to save expense, a method of reproduction of the original papers has been adopted which is somewhat unusual in Great Britain, to quote from Sir Richard Gregory's preface, "To have set up the papers again in a uniform type would have involved the Council in greater expense than was contemplated when the project of publishing the volume was conceived. It was decided, therefore, to adopt the less costly method of lithophotography or 'offset' printing for the work. By this process the original pages are photographed, and the plates thus made are used for printing, with necessary adjustments of portions of pages, and with new or supplementary matter set up in type in the usual manner." I think there will be general agreement that the experiment has been entirely successful. The printing is obviously not quite so sharp as in the originals, but the majority of readers would not notice this unless their attention were directed to it. Personally I welcome this reproduction of the papers in their original form, for many of them made a strong appeal to me when they were first published and it is pleasant to come across the old diagrams and the old familiar type. The pleasure in reading again these old friends would have been much less if they had been re-dressed, even if in better clothes.

G. C. SIMPSON

### Scottish Medical History

*History of Scottish Medicine* By Dr. John D. Comrie. Published for the Wellcome Historical Medical Museum. Second edition. Vol. 1. Pp. 400. Vol. 2. Pp. 401-852. (London: Baillière, Tindall and Cox, 1932.) 50s. net.

IF the history of medicine in other countries is so full of human interest as Scottish medical history is shown to be in this work, we can understand its fascination. The appeal is not merely medical but also covers the whole range of the allied sciences. Moreover, a nation's medical history is so intimately associated with that of its people and its progress, that laymen, as well as physicians and men of science, will find instruction and enjoyment in these volumes of Scottish medical history.

Dr. Comrie, the author, has been for the past twenty-four years lecturer on the history of medicine in the University of Edinburgh. The book shows him to possess highly specialised knowledge of his subject, combined with the ability to clothe his facts in a fascinating literary garb. He is obviously convinced that illustrations are an

essential adjunct to the appreciation of historical records, serving, as they do, not only to gratify the eye but also to make the retention of facts easier and perusal of the work more pleasurable. His illustrations are lavish, they are obviously also authentic and apt. A special word of praise may be accorded to their quality and clearness of reproduction. This part of the work, as well as the writing, has obviously been done by a master hand. We refer particularly to this point because it happens, more often than not, that well-written works of this kind are spoiled, or lowered in value, by poor and inadequate illustrations.

The fact that the work is published for the Wellcome Historical Medical Museum indicates that exceptional resources have been available to the author in addition to those he himself could command. Further, it is obvious that the initiation and personality of Sir Henry S. Wellcome, who contributes an interesting foreword, have been moving forces in the production of these two handsome volumes which contain, not merely a clear, concise, and complete historical review of Scottish medicine, but also establish themselves as the standard work on this subject.

The period covered is a very wide one. It goes back to the stone and bronze ages, during which we learn, from photographs of remains discovered in Scotland, that trephining and other complicated operations were carried out at that remote time by means of crude flint and metal instruments.

Early monastic and medieval medicine, with its interesting admixtures of folklore, herbalism, and superstition, affords much interesting reading and the opportunity of reproducing curious Gaelic medical manuscripts, in colour and otherwise. The translations of these early medical writings display their quaintness. For example, we read

"*Margarita, i.e.* a pearl. This stone is cold dry, and is found in a shell. And it grows in this way. When the shell opens it takes in its fill of poisonous dew, closes around it, and turns it into stone. The pearl that has a natural hollow in it is best, if also white. It is comforting in heart affections, and is put in electuaries. And if you wish to make the pearl white, give it to a pet pigeon to eat, and let it be left in its crop (stomach) for three or four hours. Then cut up the bird and remove the stone, and it will be pure, clear, brilliant thereafter."

In the fifteenth and early sixteenth centuries public health regulations for the prevention of infectious disease were instituted, and it is recorded as a result that plague was stamped out of Scotland in 1648.

Reference is made to the interest taken by James IV of Scotland in alchemy, in the pursuit of which he was assisted by a physician named John Damian. This leads to a description of the transition from alchemists to chemists.

So the story proceeds, for the maintained interest justifies the use of the word 'story' for this fascinating history. We read of the origins of the Scottish Colleges of Physicians and Surgeons, and of the universities and medical schools which established the reputation of Edinburgh, Glasgow, and other Scottish cities throughout the world. We read about the foibles of the early professors, which are illustrated by anecdotes and contemporary caricatures, and finally we have placed before us, in picture and story, a panorama of Scottish pioneers in medicine and the allied sciences.

The "History of Scottish Medicine" will interest everyone who loves history or science. To the student it will be doubly attractive, because its charm of style is supplemented by a business-like method which provides very full references to all sources of information, and an index which is an example of what this part of a work of reference should be.

#### A Mycological Classic

*Selecta Fungorum Carpologia of the Brothers L. R. and C. Tulasne*. Translated into English by W. B. Grove. Edited by Prof. A. H. Reginald Buller and Dr. C. L. Shear. Vol. 1. Pp. xxx + xxv + 247 + 5 plates. Vol. 2. Pp. xxiii + 302 + 34 plates. Vol. 3. Pp. xviii + 206 + 22 plates. (Oxford: Clarendon Press, London: Oxford University Press, 1931.) 126s. net.

THE foundations of knowledge of the fungi as living plants were securely laid in the sixth decade of the last century by the work of Anton de Bary and the two Tulasne brothers. That of de Bary has had the widest influence, aided materially by the English translation, the "Comparative Morphology and Biology of the Fungi, Mycetozoa and Bacteria", which has been the standard textbook of English-speaking mycologists for more than forty years. The great folio volumes in Latin of the Tulasnes have been, no doubt, dipped into by many an eager young mycologist, and their magnificent plates were widely used, but the Latin is not easy and few can have had the courage to attempt systematic reading of it.

At last, after seventy years, the three folios of the *magnum opus* of the brothers, the "Selecta Fungorum Carpologia", have been translated into

English in a form and style which challenge comparison with the originals, and are a worthy monument to English learning and English printing. The production of these sumptuous volumes was made possible by the financial support of some half-dozen American and British patrons of science, and in Mr W B Grove a translator was found who combines in an unusual degree Latin scholarship with mycological knowledge. The Oxford University Press has rivalled the original production of the Imperial Press at Paris and faithfully reproduced the work in the almost lost grand manner of typography and in the technically excellent collotype copies of the famous engraved plates. The editors, Prof A H R Buller of the University of Manitoba and Dr C L Shear of Washington, may well feel satisfied with the result.

Louis René, the skilled microscopist and deeply learned student of fungi, and Charles, the superb draughtsman and scarcely less ardent mycologist, worked, as they lived, in closest harmony. When the first volume of the "Carpologia" was published in 1861, spontaneous generation was still an open question, the fungi being, of all plants, those that were held by some of the famous men of science to illustrate best the origin of organisms from the disordered juices or putrefying elements of the matrix in which they appeared. It was the aim of the brothers to show that every fungus arose from a pre-existing one, reproduced by seed-like spores, however much polymorphism might make it difficult to follow the process. They were the first to study development and to trace through different stages the gradual course of evolution that is characteristic of many fungi. This volume may be considered to have established finally the claims of the fungi to be regarded as separate living plants, propagating their like. It is enriched by a wealth of notes, covering almost the whole range of the fungi and bearing witness to the extensive knowledge of these organisms possessed by the authors.

In the closing pages of the first volume and in the two following ones, more than 200 species of Ascomycetes are described, nearly 150 of these being figured, including all those that were regarded as new to science. Most of the descriptions are based on close field collecting and repeated observation of the association or succession in Nature of the different forms that were linked into the one life-history, supplemented by the excellent microscopic preparations of one brother and the artistic ability in depicting them of the other. Methods of growing the fungi in artificial culture were not then available and the complicated succession of

spore forms was perforce followed mainly in the field. It is natural that some of the life-histories have not stood the test of accurate proof afforded by pure culture work, and it is perhaps a reproach to mycology that others must still be classed as not proven. But it is astonishing how many were rightly interpreted and how little escaped these indefatigable workers. The discussion on spermatia and the obvious disappointment of the authors that they were unable to assign to them with certainty the sexual functions that they believed them to possess, is interesting reading after seventy years, when these functions have but recently been established in the rusts and are still only suspected in other fungi.

The "Carpologia" may well be regarded as, in the words of its translator, "one of the supreme triumphs of science." Observers as minute and accurate, artists as dexterous, engravers as wonderful, printing as superb, have indeed existed—but nowhere else can they be found in such a perfect combination. This is high praise, but who shall say that it is not justified?

#### Photographic Methods

- (1) *Photography its Principles and Practice* By C B Neblette. Second edition. Pp xxii + 615 (London: Chapman and Hall, Ltd, 1931) 30s net.
- (2) *Wissenschaftliche Photographie eine Einführung in Theorie und Praxis* Von Prof Dr E v Angerer. Pp viii + 185 (Leipzig: Akademische Verlagsgesellschaft m b H, 1931) 12 80 gold marks.
- (3) *The Technique of Colour Photography* By Frank R Newens (Blackie's "Technique" Series) Pp x + 101 + 6 plates (London, Glasgow and Bombay: Blackie and Son, Ltd, 1931) 4s 6d net.
- (4) *Photographic Amusements including Tricks and Unusual or Novel Effects obtainable with the Camera* By Frank R Fraprie and Walter E Woodbury. Tenth edition revised and enlarged. Pp. viii + 271 (London: Chapman and Hall, Ltd, 1931) 15s net.
- (5) *The Amateur Cinematographer's Handbook on Movie Making* By Robert Dykes. Pp 109 + xix (London: British Periodicals, Ltd, n d) Paper, 2s, cloth, 3s 6d.

IT is a regrettable fact that good textbooks of photography are rare. The first two of the five books in the group under review are, therefore, specially welcome.

(1) Mr Nebllette has been a teacher of photography for some years. His book is already well known and is considered to be one of the best elementary textbooks of photography available in English. It sets out and explains in a straightforward way the principal photographic processes and apparatus. It is therefore invaluable as a reference book. The book also contains a considerable amount of theoretical discussion. The chapters on sensitometry and the theory of development contain an account of the contributions made by Hurter and Driffeld to our knowledge of the behaviour of photographic materials. Attention is directed in this new edition to the unsuitability of the Hurter and Driffeld (H and D) method of computing 'speeds', and the reader is referred to various recent papers in which the difficult problem of the interpretation of sensitometric data is discussed more fully. This method is employed throughout the book. The main principles are stated, as a rule, fairly clearly, and an inquiring student is then referred to a list of more detailed books and papers on special points. Indeed, the book is very well documented, each chapter has a list of related general works, and in the appendix there is a forty-page bibliography of most of the important scientific papers on photographic subjects. In addition, there is a good author and subject index.

Some of the theoretical discussions do not, however, reach a very high level. The chapter on photographic emulsions is confusing. The discussion of the chemical mechanism of development is marred by a few paragraphs which are incomprehensible. We are told, for example, that "The ionised hydrochinon loses two anions which unite with and neutralise the two silver cations forming metallic silver, the two oxygen ions combine to form quinone and the bromine anion unites with the sodium cation to form sodium bromide" (p 256).

(2) Prof. von Angerer gives us also an excellent introductory textbook of photographic science. It is not really an elementary textbook, the net has been cast far wider than for Mr Nebllette's book, and in a small space a vast collection of facts about photographic materials and apparatus is brought together and discussed in a way which is admirable. The use of photographic methods as aids to research, for example, in spectroscopy, receives considerable attention. In a very considerable degree these two books are complementary.

The remaining three books deal in a practical way with their special branches of photography.

(3) That of Mr Newens is a very clear and pleasantly written account of colour photography

as it may be practised by the amateur. The various methods are thoroughly explained by coloured diagrams, and the working instructions are plainly set out. No attempt is made to explain, in anything but the barest qualitative way, the theory of colour photography.

(4) Mr Fraprie has brought up to date an old book "Photographic Amusements" has now reached its tenth edition. It was first published in 1896. As its name implies, it describes a variety of photographic tricks. Some of these are, of course, trivial enough, just suitable to amuse a child, but many useful workshop methods are described. Notable among the latter is the process known as 'player type', by which full-size copies of drawings may be made without distortion. Of the newer amusements included in this edition is that of trick cinematography, a field of surpassing opportunity. The book affords ample evidence that photographs are not always truthful.

(5) Mr Dykes has chosen a rather misleading name for his book. Anyone who imagines that the "Amateur Cinematographer's Handbook" is a handbook of the conventional type, with neatly tabulated, easily found information, will be disappointed. It is merely a somewhat rambling, though quite interesting talk about amateur 'movie' making. There is little attempt at arrangement, and the descriptions of apparatus are not very clear.

### Short Reviews

*The Fauna of British India, including Ceylon and Burma* (Published under the Authority of the Secretary of State for India in Council) Edited by Lieut.-Col J Stephenson. *Cestoda*. Vol. 2. By Dr T Southwell. Pp ix + 262. (London: Taylor and Francis, 1930) 15s.

In this volume, Dr Southwell gives a systematic account of the super-family Tæmoidea (or Cyclophyllidea), which comprises a dozen families, including several of great importance, as they contain parasites of man and of domestic animals. The author regards as untenable the subdivision of the genus *Tænia*, as suggested by Hall, into three genera—*Tænia*, *Multiceps*, and *Echinococcus*, based chiefly on larval characters—pointing out that when a diagnosis is required of a worm passed, for example, by a dog, no information is available whether the larval form is a cysticercus or a cœnurus. He holds that the identification should be possible on the morphological characters of the adult worm. The genus *Tænia* is accepted in its widest sense, and, owing to the impossibility of devising a satisfactory key, a table showing the principal characters of the known species is given.

The cœnurus of *T. multiceps* is well known to

occur in the brain of sheep, and the cœnurus of *T. serialis* in the subcutaneous tissues of the rabbit. Dr. Southwell directs attention to the discovery by Gaiger (1907) of a cœnurus in the connective tissue of the goat, which was held to be that of *T. serialis* (later named by Hall *T. gaigeri*), and the finding by Dey (1909) of the same stage in the connective tissue and also in the brain of the goat in India. He regards the species *multiceps*, and these others, *serialis* and *gaigeri*, as very closely related, and possibly identical, and suggests that the goat provides conditions in both brain and connective tissue for the development of the larval form, whereas in the sheep and in the rabbit the larval form develops respectively in only one of the sites.

For most of the species, Dr. Southwell not only states the principal structural characters but also notes the mode of infection of the host and the site of the larval form in the intermediate host. A classified list of Cestodes from India, with their hosts, a classified list of the hosts with their Cestodes, and an adequate systematic index conclude this useful volume. The illustrations, with the exception of the photograph on p. 27, are clear and adequately lettered.

*Fourth Congress of the Universities of the Empire, 1931. Report of Proceedings.* Published for the Universities Bureau of the British Empire. Pp. vii + 260. (London: G. Bell and Sons, Ltd., 1931.) 21s. net.

In this volume a number of current university problems are clearly set out and competently discussed with a wealth of illustration and argument from many widely differing points of view. Organised as it was, in the light of experience gained in previous similar congresses, ample opportunities for informal interchanges of views and experiences being provided at London and elsewhere during the week preceding the scheduled meetings which took place at Edinburgh on July 7-10, the fourth quinquennial gathering of representatives of seats of learning in all parts of the Empire was an ideal forum for the discussion of such matters.

The first subject of discussion was the university graduate in commerce and industry. This was introduced by Sir Robert Waley Cohen, of Cambridge, who justified its prominent place in the agenda by reference to the world-wide economic revolution now in progress necessitating the re-laying of the very foundations of commerce and industry, and the consequent need, in this field, of men of high character and trained intellect. In subsequent sessions the Congress dealt with the conditions of admission to universities, facilities for overseas students in British universities, general honours degrees, the Ph.D. and other post-graduate degrees, and post-graduate study in medicine and surgery.

The inaugural addresses, with which each day's proceedings opened, ranged over a wider field, and of one (Lord Meston's "A Layman looks at the University") the chairman observed that the author had put his finger on all the major problems which those responsible for the conduct of university teaching have felt to be pressing upon them in

the last few years. Although, naturally, 'laymen' took but a small part in the proceedings, the record as a whole is eminently readable and there are few pages that have no appeal outside university circles.

*Úvod do Radioaktivity.* Napsal Dr. F. Běhounek a Prof. Dr. J. Heyrovský. Pp. 116. (Praha: Jednoty Čs. Matematiků a Fysiků, 1931.) 24 Kč.

It was in pitchblende from the mines of Jáchymov (St. Joachimsthal) in Bohemia that Prof. and Mme. Curie first discovered radium. The ores from these mines now yield radium preparations representing two to four grams of the pure element annually. In spite of the interest in the subject, the present volume is the first book by Czech men of science on radioactivity. It deals with the discovery and phenomena of radioactivity, the preparation of radium products and their physiological action, geophysics, cosmic radioactivity, and the technique followed at the Czech mines and extraction plant and at the Prague Radiological Institute.

Prof. Běhounek accompanied General Nobile's expeditions to the north pole in 1926 and 1928, and his experiments on radioactivity of the atmosphere in the arctic and at high altitudes is embodied in the chapters on geophysics and cosmic radioactivity. Prof. Heyrovský is best known for his polarographic researches with the dropping mercury cathode, and this method has found application in the examination of radium-barium salt mixtures.

The authors have introduced several unusual features in their treatment of the subject. Thus, stress is laid upon the experimental aspect of radioactivity and theoretical considerations are dismissed very briefly. The general reader will be particularly interested in the account and photographs of the methods of extracting radium from the large quantities of ores needed, and in the procedure in studying the use of this element in medical treatment.

*The Annual Register: a Review of Public Events at Home and Abroad for the Year 1931.* Edited by Dr. M. Epstein. Pp. xv + 316 + 169. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1932.) 30s. net.

THE history of the world, which it is the main function of this annual volume to place on record, has gone through a troubled year, with many changes and upheavals in the old order of things, but the "Annual Register" maintains its old form and arrangement. British and Imperial history occupy, in a most readable narrative, about one-third of the book. Then comes the history of foreign States in about the same compass, followed by the usual chronicle of events, surveys of literature, art, drama, science, finance, and commerce, and finally the short biographies of eminent men and women in the year's obituary. The Constitution of the new Spanish Republic is given in full. The survey of the year's science occupies about eleven pages, divided between the biological and physical sciences. It is noteworthy that this work of reference has now reached its hundred and seventy-third year of issue.

## The Hereditary Transmission of Acquired Characters\*

By Prof J B S HALDANE, F R S

"Enfin les efforts faits par le besoin pour obtenir des facultés nouvelles, se trouvant aidés du concours des circonstances favorables, créent avec le temps les organes nouveaux qui sont propres à ces facultés, et qu'ensuite un long emploi développe"

LAMARCK, *Discours d'ouverture de l'an XI*

"Nil ideo quoniam natumst in corpore ut uti Possemus, sed quod natumst id procreat usum"

LUCRETIUS, *De Rerum Natura*, IV 834

THE tendency of men, animals, and plants to resemble their parents has been known for some thousands of years, although it is only since the time of Mendel that it has been realised that this is only half, and not necessarily the most important half, of genetics. Given that principle, men naturally argued somewhat as follows. A fat pig generally has fatter children than a thin pig. If we fatten up this thin pig, his children will be fat. This is a straightforward argument, as good as most used in politics. But it is, as we shall see, fallacious. The difference between a fat and a thin pig may be due to two causes. The two pigs may be of the same breed, but have had a different diet, or they may be of different breeds, but have had the same diet. Finally, of course, both causes of difference, external and internal, may be operating. Now, those who, like Lamarck, believe in the hereditary transmission of all acquired characters, take the view that if fatness has been produced for some generations by the external cause of diet, it will later go on being produced by internal causes when the external cause is removed. There is nothing impossible in this supposition, but if we put it that way, its *a priori* probability appears less.

As the result of experimental work, some of which I shall summarise, the majority of geneticists take the view that characters acquired as the result of external influences are rarely inherited, so rarely that the exceptions are of little importance either for the explanation of evolution or the practical problems of the breeder or eugenicist.

Last year Prof E W MacBride restated the case for Lamarckism in a discourse under the title of "Habit, the Driving Factor of Evolution"†. Prof MacBride's contributions to the science of embryology have been most distinguished, and his apparently heretical views on the historical process of evolution, for example, concerning the descent of the vertebrates from a common stock with the echinoderms, have been confirmed by subsequent work. But just as the best of historians may not be the best judge of the politics and economics of his own day, so an eminent student of the history of evolution may conceivably be mistaken as to its causes. These must be decided on by observing the

changes which actually occur in living organisms under controlled conditions.

I shall begin by giving an example of one of the rather rare cases where an acquired character is unquestionably inherited. If we cut off the growing point of a young tomato plant it produces new shoots. A few of these regenerated shoots are somewhat abnormal. The leaves are larger, and if these shoots are cut off and rooted, a new race of tomato is produced. It differs from the original stock in the following respects. The leaves are thicker, less dissected, and have more anthocyanin. The fruits are smaller but more numerous. The whole *tempo* of the plant is slower. It does not start growth so quickly, but continues for a longer time, and finally reaches a larger size‡. What is more, not only do the abnormal plants transmit the character by vegetative propagation, but if their flowers are self-fertilised the seedlings resemble the abnormal parents. They can only be crossed with the original type with great difficulty, and the hybrids are extremely sterile.

Now, if we examine a dividing nucleus of the ordinary tomato, we find 24 chromosomes. The abnormal type has 48, or double this number. Such plants are called tetraploids, because they have four similar sets of chromosomes, instead of two as in normal tomatoes. We know that the chromosomes are responsible for most, if not all, of the heritable differences between different tomatoes. By our injury we have provoked a stable and self-perpetuating rearrangement of the physical basis of heredity. Where this is possible, acquired characters are inherited.

Induced tetraploidy has doubtless been of some importance in plant evolution, and possibly in animal evolution. But it does not produce very striking changes. Moreover, there is no suggestion that they are adaptive, that is to say, that the tetraploid plants are better off than the diploid in any way, in particular, they do not appear to resist mechanical injury any better. The importance of the Lamarckian hypothesis for evolution lies in the possibility that adaptive changes, such as undoubtedly occur in the life of an individual, are handed on to its offspring.

It is also worth noting that in this case the change is only found in the descendants of a particular cell the nucleus of which has failed to divide. It is not transmitted to other parts of the plant. Now, in the higher animals the cells which will form the future germ cells are cut off at an early stage from the rest of the body, and are carefully shielded from change by a series of processes regulating the temperature and chemical composition of the blood going to them. This argument appealed to Weismann. But it does not apply to the higher plants, where the cells of any growing point may give rise to germ cells. In any event, it is not a very sound

\* Friday evening discourse delivered at the Royal Institution on April 22. (Since the lecture was written, I find that Prof W E Agar has covered much of the same ground and anticipated many of my conclusions in the Braisford Robertson memorial volume of the *Australian Journal of Experimental Biology* (1932) — J B S H.)  
† NATURE, 127, 933, June 20, 1931.

‡ I must thank Dr Sansome for permission to quote his unpublished observations.

argument, even in higher animals, as the environment of the germ cells is not absolutely constant

I will now cap my positive example with some negative ones. If plants or animals are inbred for many generations, they approximate to what is called a pure line. Within any such line, differences are not inherited. All members have the same hereditary make-up. The differences between them are due to environment, and are not handed on to the offspring, as appears from Table I (from Johanssen). The progeny of the heaviest beans chosen within the line were no heavier than those of the lightest. Within such a line neither Lamarckian transformation nor Darwinian selection produces any measurable effect.

Exactly the same results were obtained by Wright within pure lines of guinea-pigs. The guinea-pigs born of old mothers had more white in their coats and fewer toes than the average, but their offspring did not resemble them in these respects. Clearly a transformation of a pure line would be a much more notable achievement than

be called an instinct, a tropism, or a reflex, according to taste. Now, it is a well-known fact that cave-dwelling animals are often blind and colourless. Payne bred *Drosophila* in darkness for 69 generations. After ten generations he believed that he had diminished their tendency to fly towards a light. But after 69 generations there was no change in colour or structure, and the effect on behaviour, as measured on 1000 flies, was negligible. The flies were given ten minutes or more to adapt themselves to light, and were then placed at one end of a dark tube nine inches long, the other end of which was illuminated. About a quarter of the flies did not react within a minute, and were 'counted out'. This proportion was not altered by breeding in darkness. On the other hand, the speed of reaction was very slightly increased. There is certainly no suggestion that the flies had lost the tendency to move towards light through disuse.

The alternative explanation of blindness in cave-dwellers is that animals suffering from hereditary blindness have no tendency to leave a cave, and hence their descendants populate it. It is interesting that a race of the same fly, selected on account of a peculiar body colour, does not move towards light, and might therefore remain in a cave where normal flies would tend to leave it.

We now turn to some of the experiments on which the neo-Lamarckian

TABLE I

| Year | No. of Beans | Mean Weight of Parents |       |            | Mean Weight of Offspring |              |               |
|------|--------------|------------------------|-------|------------|--------------------------|--------------|---------------|
|      |              | Light                  | Heavy | Difference | Parent Light             | Parent Heavy | Difference    |
| 1902 | 145          | 600                    | 700   | 100        | 631.5 ± 10.2             | 648.5 ± 7.6  | + 17.0 ± 12.7 |
| 1903 | 252          | 550                    | 800   | 250        | 751.9 ± 10.1             | 708.8 ± 8.9  | - 43.1 ± 13.5 |
| 1904 | 711          | 500                    | 870   | 370        | 545.9 ± 4.4              | 566.8 ± 3.6  | + 20.9 ± 5.7  |
| 1905 | 654          | 430                    | 730   | 300        | 635.5 ± 5.6              | 636.4 ± 4.1  | + 0.9 ± 6.9   |
| 1906 | 384          | 460                    | 840   | 380        | 743.8 ± 8.1              | 730.0 ± 7.2  | - 13.8 ± 10.8 |
| 1907 | 379          | 560                    | 810   | 250        | 690.7 ± 7.9              | 676.6 ± 7.5  | - 14.1 ± 10.9 |

After Johanssen. Weights in milligrammes

anything done in a mixed population, because in the latter case selection is known to be effective, and it is up to the Lamarckian to prove that he has not exercised selection.

The two experiments which have lasted the greatest number of generations have both been performed on quickly breeding arthropods. Agar bred the little water-fleas *Simocephalus* and *Daphnia* for 101 and 79 generations respectively. These animals reproduce by parthenogenesis, under the conditions of Agar's experiment, the life-cycle being completed in a week or a little longer. They swim by means of their second antennæ. If one branch of these is cut off when the animal hatches, the feather-like setæ are usually, though not always, regenerated. It might have been expected that after a hundred generations the progeny of the operated animals might have shown an increased aptitude for regeneration. This was not the case. If anything, they regenerated very slightly worse than the controls, but the difference was not significant. Agar also tried the effect of selecting those animals which regenerated best. He got no effect at the end of forty generations. This was to be expected, as he worked with a clone, within which, as within a pure line, there are no heritable differences.

It might be hoped that better effects would be obtained where the character studied was of a more psychological kind. The fly *Drosophila melanogaster* generally moves towards a light. This may

ian case is based. Except those of McDougall, which are in a class by themselves, none of these has been conducted on approximately pure lines. Since we know that in a mixed population selection is effective, we shall see whether this cannot account for the observed changes. I will therefore consider the experiments cited by Prof. MacBride.

Durken worked with *Pieris brassicæ*, the cabbage white butterfly, the pupæ of which become green when the larvæ are kept under yellow, orange, or green glass. This discovery was not made, as MacBride states, by Durken, but by Wood in 1867, and very fully described by Poulton in 1887. In a typical experiment of Durken's, 4 per cent of the pupæ reared in normal light were green, as were 63 per cent of those reared in orange light. Only the moths emerging from the green pupæ were bred from, and these gave 98 per cent green when the caterpillars were kept in orange light, and 48 per cent in normal daylight. Now, one cannot prove that Durken had not observed the transmission of the effect of the light. But there is no evidence for this hypothesis. He had selected the green fraction of the pupæ, and naturally enough he got more greens in the next generation. Selection is generally quite effective except within a pure line, and there is not a shadow of evidence that Durken observed anything but the effects of selection.

For comparison, let us study a more scientifically

conducted experiment of the same kind, namely, the late Dr Bateson's experiment (posthumously published from his notes by Sir Daniel Hall) on 'bolting' in sugar beets and mangolds. On an average, about 5 per cent of the plants in a field of sugar beets bolt, that is to say, they throw up a stem and set seed during their first year, so that the roots are denuded of sugar and worthless. The rest behave as biennials. Mangolds show a similar phenomenon. It was known that early sowing promotes bolting. Now, Bateson, we may assume, started out with the hypothesis that bolting may be due to internal or external causes. So, instead of sowing mangolds in the open in April, he sowed them under glass in December or January, and planted them out in April. Thus any plant with an inherent tendency to bolt was given the fullest opportunity to do so. Sutton's Prize Globe mangold gave only 2 bolters out of 390 when sown in April. But when sown in December, 8 out of 19 bolted. The 11 non-bolters were used for seed, and none of their progeny bolted, even when sown in January. However, some seedlings from this family were subjected to severe temptation to bolt by sowing in December. Ten out of 136 (a much smaller proportion) bolted, but 213 of the progeny of the non-bolters refused to bolt when sown in January. In the case of sugar beet, the proportion of bolters was greater, and four generations were needed to eliminate the habit.

Bateson also made the converse experiment of trying to establish a race which always bolted. He did not get any appreciable increase of bolting when he selected the progeny of plants which had bolted as the result of early sowing. But by sowing seed of 12 plants out of 312 which had bolted when sown in April, he got 41 per cent of bolters. All this is entirely intelligible on the theory that bolting, in so far as it is an acquired character, is not inherited. If Durken had bred from the pupæ which refused to turn green even in orange light, he would no doubt have been able to eliminate the tendency to turn green, and if he had bred from those which turn green in ordinary light, he would presumably have obtained a more striking change in the next generation than was actually found. In order to prove the Lamarckian theory, it would be necessary either to start with a pure line or not to practise selection. Harrison, who worked with the turnip white butterfly, *Pieris rapæ*, which normally gives about 20 per cent of green pupæ, obtained more striking effects than Durken, as he only appears to have eliminated 7 per cent in one generation and 5 per cent in the next, and yet obtained 31 pupæ, all green, in normal daylight. While Harrison's case is thus far stronger than Durken's, it cannot be regarded as conclusive unless similar results are obtained without selection, either artificial or natural.

(To be continued)

### The Transport Problem in the United States

IN the century and a half which has elapsed since the American steam-boat pioneers, Fitch and Rumsey, began their experiments on the Delaware and Potomac rivers, transport in the United States has undergone many remarkable changes. From the work of those pioneers, in the course of years, came a magnificent fleet of river steamers, her engineers next gave the country the most extensive railway system in the world, while to-day the automobiles are so numerous that there is one for every five of the population, and transport by air is making rapid progress.

America is what it is largely because of its transport, without which its prairies would still be uncultivated and its mines unexploited. One of the landmarks in the history of that transport was May 10, 1869, when the last spike—a golden one—was driven in the railway which connected the Atlantic coast with the shores of the Pacific. On that occasion Philadelphia rang the old Liberty Bell, New York fired a hundred guns, Buffalo sang "The Star-Spangled Banner", and there was even a thanksgiving service in Trinity. There then seemed no end to the benefits to be gained from the railways, which to-day, by the irony of fate, are faced almost with bankruptcy.

Like our own railway system, that of the United States was built up entirely by private enterprise, and the present position of the railways is much the same as our own, some think it is somewhat more complex. What that position is, and what remedies

are suggested so that the railways can continue to fulfil their part in the national economy, are well stated in three contributions printed in the first issue for the current year of the *Proceedings of the American Philosophical Society*. The three papers are entitled (1) "The Railroad Situation. Some Suggestions as to the Way Out", (2) "A Way for the Railways to Keep Out after they are Out", and (3) "Co-ordination as a 'Way-out' of the Transportation Crisis"—the respective authors of which are Dr E. R. Johnson, Mr A. B. Johnson, and Mr G. L. Wilson. Of the three papers, the first is much the longest and gives a record of all the factors of the problem.

The United States railway system has some 250,000 miles of track, and the rolling stock includes about 67,000 locomotives, 57,000 passenger cars and 2,500,000 freight cars, the results of the development of a hundred years. The public roads include 3,000,000 miles of highways, of which some 700,000 miles are surfaced and about 128,000 miles are mainly of concrete. About 50,000 miles of streets are constructed or rebuilt annually, the expenditure on which reaches 2,000,000 dollars.

The number of automobiles of all kinds registered in the United States at the end of 1931 reached the astonishing figure of 23,042,840, the result of thirty years' development, and the number of companies engaged in freight traffic services runs into thousands. There are no complete statistics of the freight carried by motor vehicles, but not only are

fruit, vegetables, and live stock now conveyed by road, but also such things as coal and cotton. Of the 4,000,000 bales of cotton grown in Texas in 1930, 1,200,000 reached the ports by motor vehicles. But severe as is the inroad made on the freight traffic of the railroads by motor wagons, still more severe is that due to the private motor car and the motor buses. In 1920 the passenger earnings of American railroads were nearly 21 per cent of their total operating revenues, but in 1930 this figure had fallen to 13·8 per cent, and the showing for 1931 was even worse.

Added to the competition from the roads is that due to the carriers by water, for inland and coast-wise traffic. At the time the Panama Canal Act of 1912 was passed, several railroad companies had steamship lines on the Great Lakes and on the Pacific and Atlantic seaboard. By that Act, however, the companies were prohibited the use of the Canal for vessels owned by them, and other restrictions were placed on their maritime activities. At the close of the War, too, the United States possessed a large surplus of ships. Many of these were sold at a low figure and placed in service, while the Government itself entered the business of inland water transportation. The schemes have never paid their way, and, says Dr Johnson, "it is hard to justify the continuance of business operation on this basis by the Government in competition with private enterprise."

Traffic has not only been leaving the rails for the roads and waterways, but also for underground pipelines for distributing oil, natural gas, and gasoline. Formerly nearly all petroleum was sent by freight cars, and it involved a large tonnage. In 1929 only 4·5 per cent of the production was transported by rail. There are now 100,000 miles of crude oil pipelines in the United States, 65,000

miles of pipelines for the distribution of natural gas, and in 1931 there were also 3800 miles of gasoline pipelines. The rapid increase in the use of oil and gas has had a marked effect on the coal output of the country, and it has been estimated that in 1929 natural gas was substituted for about 77,500,000 tons of bituminous coal.

As to civil aviation in the United States, a recent return shows that American air transport companies now operate over routes with a total mileage of 51,000 miles, and the machines cover a total distance of 150,000 miles every twenty-four hours.

The problem of co-ordinating the great and varied transportation services of the United States, it will thus be seen, is a very complex one. It is one dealt with by Dr Johnson and Mr Wilson in their respective papers, both of which are worthy of the attention of the authorities in Great Britain. In reviewing the constructive and corrective measures required, Dr Johnson mentions the reduction of unprofitable train services, the operation by the railways of both passenger and freight motor services, a reduction in the competition among the railways themselves, the consolidation or grouping of the railways into a limited number of systems, the co-ordination of rail, road, water, and air services, and the regulation of all transport agencies by the Government, according to a sound and equitable national policy. What co-ordination means and how it can be effected is dealt with fully by Mr Wilson, who says "The trend towards co-ordination has proceeded to the point that we can predict that the great railroads, steamship companies, electric railways, and other specialised carriers will tend to become *transportation* companies offering a variety of transportation services to shippers and travellers that will supply the needs and fit the pocket-books of their patrons."

### Polar Lights\*

By Prof S CHAPMAN, F.R.S.

MANY of the principal facts concerning the polar lights, or aurora, have long been known. For example, John Dalton, the great chemist, who observed the lights carefully for many years, and thought deeply upon them, was well aware of their close connexion with the earth's magnetism as shown by their occurrence mainly in regions centred at the magnetic (rather than the geographical) poles, by their tendency to be extended in the direction transverse to the magnetic meridian, by the near agreement between the direction of auroral rays and the local direction of a freely poised magnetised needle, and by their parallelism, in time of occurrence and in intensity, with magnetic disturbances or storms. His ideas as to their height, on which Cavendish had made careful measurements, were also in general accord with modern determinations.

Modern observations of auroræ have advanced

our knowledge chiefly by establishing the height and situation with incontrovertible accuracy, by the methods of Størmer and his followers, and by the interpretation of the beautifully coloured auroral light, with the aid of the spectroscope and the great body of modern knowledge concerning atomic and molecular spectra.

Much remains to be done before the full fruits of the study of the auroral spectrum are garnered, but two main facts are established: a large part of the spectrum consists of bands due to singly ionised nitrogen molecules, while the famous green line, a standing challenge to spectroscopists for many decades, has been shown by McLennan to be emitted by neutral atomic oxygen, he, his colleagues, and others have traced the line in detail to its source in a particular transition occurring in the oxygen atom. Through the initiative of another active investigator of the auroral spectrum, Vegard, the Rockefeller Foundation has instituted an auroral observatory, maintained by the Norwegian Govern-

\* Substance of a lecture delivered at the annual general meeting of the British Science Guild on May 25

ment, at Tromsø, special attention will be devoted at this well-equipped and favourably situated observatory to this side of auroral research. A further remarkable observational discovery concerning the aurora, due to Størmer, is the recognition that the specially high auroræ, sometimes seen in the west after sunset, or in the east before sunrise, are in the part of the atmosphere, beyond the earth's shadow, still traversed by the sun's rays.

On the side of theory, the advances have been of comparatively recent date. Birkeland laid the foundations, by his speculations and experiments, on which Størmer has reared a great mathematical superstructure, developing the hypothesis that the aurora is due to electrically charged particles from the sun, these are deflected by the earth's magnetic field towards the polar regions, thus explaining the geographical incidence of auroræ. Størmer has deduced from this hypothesis the existence of the two auroral zones, and many other observed features of the aurora. But valuable and successful as the present theory is, it suffers, as Schuster indicated, from a great and deep-lying defect. Of the forces which guide the particles, the theory considers only the electromagnetic, whereas there will also be important electrostatic forces, which the theory ignores, the latter arise from the mutual influence of the particles, which must be partly positive and partly negative, in nearly equal numbers. A new theory must be built up, taking both sets of forces

into account, this promises to be exceptionally difficult, and only the merest beginning has yet been made. It is to be hoped that, in the future development of the work, much of the existing theory will find a place, being preserved in a larger structure, as has happened in many other branches of physical theory, but of this it is still too soon to judge.

At the present time we stand, it is hoped, on the eve of a further advance in the observation and theory of the aurora, and of its associated phenomenon, magnetic disturbance. Expeditions are now proceeding to take up their stations at many points in and near the arctic circle, in connexion with the new International Polar Year for scientific research on magnetism, auroræ, and meteorology. With modern instruments and methods, a great extension of the knowledge afforded by the first Polar Year, 1882-83, may confidently be looked for. The British magnetic and meteorological expedition, led by Mr J. M. Stagg, left for Fort Rae early in May, among other items of its programme is included the determination of auroral heights, from two stations connected by cable or radio. Another British expedition, under Prof E. V. Appleton, will leave shortly for Tromsø, to determine, by radio methods, the amount, distribution, and changes of ionisation near the auroral zone, its results should be of extraordinary interest and value for both auroral and magnetic research.

### Obituary

SIR THOMAS LEGGE, C.B.E.

THE death on May 7 of Sir Thomas Morrison Legge, late Senior Medical Inspector of Factories, deserves more than a formal note, for his official record in this capacity was coterminous with the chief reforms in factory hygiene which have occurred. In securing these he played an essential part.

Legge was the son of a distinguished Chinese scholar. After taking his degree with honours at Oxford, he investigated public health conditions in European countries, and described their municipal administration in a volume which may still be referred to with advantage. After serving as secretary of the Royal Commission on Tuberculosis, 1896-98, he worked in public health in Brighton, and afterwards was appointed the first Medical Inspector of Factories and Workshops, a post held by him for nearly thirty years. In this capacity he undertook many important investigations, among others, the relation of cataract to the glare in a glass-blowing factory, the causation of nystagmus, and the origin of various other industrial conditions, in which questions of compensation arose.

Legge gave the Milroy lectures before the Royal College of Physicians on anthrax, and some years later his distinction in industrial medicine was indicated by his receiving from the same College the Bisset Hawkins medal as a pioneer in public health. He was instrumental in securing the

establishment of an official disinfecting station for wool coming from anthrax-infected countries.

Legge's life-work was largely concerned with investigations of industrial lead poisoning and with securing regulations against these risks, and the record of steadily diminishing incidence of cases of lead poisoning year by year is eloquent testimony to the success of his work and that of his colleagues. In 1921 at Geneva thirty countries, including Great Britain, had agreed to a draft Convention, under which it was intended to prohibit the use of lead paint for internal painting. In 1927 Great Britain, however, while regulating the employment of lead paint, did not make its prohibition absolute, and Legge resigned his post at the Home Office in protest, a year or two before his appointment lapsed by flux of time.

Before and after his retirement Legge did valuable work in promoting industrial hygiene, by lecturing on his subject in America and in Great Britain. He held very strongly that for medical students industrial hygiene and poisoning were left almost entirely out of the medical curriculum. He was also insistent that the psychology of the worker should be more fully studied and considered.

Throughout his life, Legge took great interest in the artistic side of the worker's work, and outside his daily work he delighted in discovering examples of old church and other stained glass. In this subject he was, indeed, an authority, and had at one time a valuable collection.

Legge's outstanding personal characteristics were modesty and unyielding integrity. He was concerned with his work, not with credit that might come from it, and it is most satisfactory, therefore, that we can now recall with gratitude his extremely important contribution to the welfare of industrial workers in Britain and in other countries

A N

#### PROF OTTO FISCHER

WE regret to record the death on April 4, after a prolonged illness, of Prof Otto Fischer, who was associated for many years with his more famous cousin, the late Emil Fischer. From the *Chemiker-Zeitung* we learn that Otto Fischer was born in 1852 at Euskirchen, near Cologne. On leaving school, he studied for a short time with Kekulé at Bonn before proceeding to Strassburg, where he began his researches on the synthesis of hydrocarbons under Adolph von Baeyer, and where Emil had already begun his career. After graduating in 1874, Otto proceeded to Charlottenburg to work with Liebermann, but two years later he rejoined von Baeyer, who had in the meantime been called to Munich. In Munich the cousins Fischer worked upon the preparation of organic hydrazines and upon the dyestuffs of the triphenylmethane group. In 1882, Emil was appointed to the chair at Erlangen, but his health broke down and, in 1884, Otto was sent to act as his substitute. In the following year, Emil accepted the chair at Würzburg, and Otto

was appointed to succeed him at Erlangen. This post he held until his retirement in 1925.

In conjunction with his assistants and students, Otto Fischer published a considerable number of papers on organic chemistry—his favourite field of research being dyestuffs. In conjunction with Dr E. Hepp, of the Hochster Farbwerke, he investigated nitrosamines and nitroso-bases, the reactions of the iminazol-group, the safranines, indulines, and fluorindines. Later he worked upon the photosensitising dyestuffs of the cyanin group. He also investigated derivatives of pyridine, quinoline, and anthracene, and he discovered the drug kairine.

#### WE regret to announce the following deaths

Prof Fritz Drevermann, professor of palæontology in the University of Frankfurt-on-Main, and editor of the *Palaontologischen Zeitschrift*, on March 16, aged fifty-seven years.

Dr Carl Leo Mees, president emeritus of the Rose Polytechnic Institute at Terre Haute, Indiana, who was twice vice-president of Section A of the American Association for the Advancement of Science, on April 20, aged seventy-eight years.

Dr Roland Thaxter, emeritus professor of cryptogamic botany at Harvard University, and honorary curator of the Farlow Herbarium, who was a member of the National Academy of Sciences and foreign member of the Linnean Society of London, on April 22, aged 73 years.

### News and Views

#### Sir Henry Wellcome, F R S

At a meeting of the Royal Society on May 26, Sir Henry Wellcome was elected a fellow of the Society under Statute 12, which provides for the recommendation by the Council for election of "persons, who either have rendered conspicuous service to the cause of science, or are such that their election would be of signal benefit to the Society." Sir Henry, who was knighted last January for his public services, has been a generous and frequent benefactor of scientific research. In 1899 he founded the Wellcome Tropical Research Laboratories in Khartoum, where the late Sir Andrew Balfour worked for many years; he established in England in 1913 his Bureau for Scientific Research and Historical Medical Museum, and in 1914 the Museum of Medical Science, including Tropical Medicine and Hygiene; in 1920 he founded the Wellcome Entomological Field Laboratory. Last year, Lord Moynihan laid the corner-stone of the Wellcome Research Institution, where the Historical Medical Museum and Museum of Medical Science will be brought together under one roof, and facilities provided for research in medical zoology, parasitology, entomology, tropical medicine and hygiene—the corner-stone, as Lord Moynihan remarked, of a long life's work. Sir Henry Wellcome's election to the Royal Society is a fitting acknowledgment of one who has done as much as anyone in Great Britain to promote the advance of the science and art of medicine.

#### Scope and Needs of Medical Research

SIR WALTER MORLEY FLETCHER delivered the Friday evening discourse at the Royal Institution on May 27, taking as his subject "The Scope and Needs of Medical Research." He pointed out that medical research covers immensely wide and varied fields of scientific activity, indefinitely wider than the important part of it which concerns the healing profession as such. Its scope has been defined for Parliamentary purposes as dealing with "the proper development and the right use of the human body in all conditions of activity and environment, as well as with its protection from disease and accident, and its repair." The development of the body includes the relatively new and rapidly growing studies of genetics on one hand, and of nutrition on the other. For the right use of the body we are concerned with personal hygiene as well as with the intricate group of problems belonging to industrial life. Here research is organised under the Industrial Health Research Board. Protection from disease covers the two great fields of preventive and of curative medicine. It deals with the genetic and nutritional control of disease, as well as with studies of infective disease at home and in the tropics. This infinitely varied field of work calls at every point for the intensive application of the primary sciences. This is well illustrated by the study of rickets, the detection of its dietetic basis, and the discovery of the relationship of light radiation to the fat-like substance

in the skin from which vitamin D is produced. Further development has involved intensive team work by physicists, chemists, and biologists, leading to the production of calciferol, the actual substance of vitamin D. This has not only made important contributions to organic chemistry as such, but also has brought improved practical powers to the medical administrator.

ANOTHER example of intensive work has been in the study of the so-called viruses, which cause widespread and often ruinous diseases in men, animals, and plants. New physical methods have been devised for their optical study and their separation and measurement by means of filters. The better study of these minute particles has not only an obvious utilitarian value, but also has extreme intellectual interest. They are units, apparently alive and reproductive, yet far smaller than any living cell which has hitherto been regarded as the minimal organisation capable of displaying life and reproduction. The whole story of medical research, whether viewed in its wide extent or followed to its intensive studies, illustrates the absurdity of the artificial boundaries that at present tend to separate the different sciences. In the schools, as Lord Chelmsford's Committee has reported, the cleverer boys are 'caught' for physics and chemistry, while the scholarship system, especially at Oxford and Cambridge, encourages a narrow specialisation which is, unfortunately, continued during undergraduate life. Most physicists and chemists proceed throughout school life and to a university degree without ever becoming acquainted with the interest of matter endowed with life. Many students lose opportunities they might have welcomed for fruitful work in the biological field, and the whole cause of medical progress suffers. Of students who proceed to medicine, many are again lost from the research field because of the great attraction offered by the natural human interest of professional work, or because of financial needs or desires.

#### Institute of Physics

LORD RUTHERFORD, presiding at the annual general meeting of the Institute of Physics, said that in the short time since its foundation, remarkable progress has been made towards the achievement of the original intentions of its founders. There has been a rapidly growing recognition of the importance of the physicist, not only in the academic world, but also in industry, and Lord Rutherford considers that the Institute can justly claim some of the credit for this. The properly trained physicist has the power to form his judgment by performing experiments, and if it be a subject where little is known, the cost of the investigation may only be a matter of a few shillings. It is very important that such an Institute should include every type of physicist among its members, and naturally to physicists in some of the sheltered posts, such as colleges and universities, it is not quite clear what particular advantages can be gained by joining the Institute, when they already have so many facilities at their own door. But taking a long view, Lord

Rutherford said, it is the duty of every physicist to join the Institute, wherever he may be, and so help on the recognition of the profession that he represents. He looks forward to the time when membership of the Institute will be considered a necessary professional qualification. The standing of the physicist in the scientific world, not only of to-day, but also of to-morrow, depends upon the support that the Institute receives.

#### Reading Rooms at the Institute of Physics

PRIOR to the annual general meeting, Lord Rutherford opened the new reading rooms at the Institute of Physics. Through the generosity of the Royal Commissioners for the Exhibition of 1851, some rooms have been allocated to the Institute for this purpose, and these have now been comfortably furnished. The Joint Library Committee set up by the Institute, the Physical Society, and the Optical Society has arranged that the libraries shall be combined for the mutual benefit of all, and thus a large number of periodicals and other books are already available for the use of members of the Institute and its participating societies. In addition, a limited number of textbooks and reference books are included in the library. In the course of his remarks, Lord Rutherford said that the opening of these rooms is another example of the co-operation of the participating societies through the Institute, which was one of the purposes for which the Institute was founded. Some of the rare old books belonging to the Physical and Optical Societies were open for inspection during the afternoon. It is hoped that authors and publishers will present suitably inscribed copies of their books, and in this way those whose attention has been directed to new books by the reviews published in the various journals of the Institute and its participating societies will have an opportunity of examining the books more carefully before procuring their own copies.

#### Game Animals of the British Empire

THE new gallery at the Natural History Museum, which is intended for the exhibition of whales, in replacement of the temporary building erected thirty-four years ago, was finished last autumn, but the economic crisis has interfered with the original plans, and, owing to lack of money, the Trustees have been unable to arrange for the renovation and removal of the large whale models. They decided that, in the circumstances, the gallery might usefully be employed for a comprehensive exhibit of the game animals of the British Empire. The open floor of the gallery has been divided into three parts, devoted to specimens from Africa, Indo-Malay, and Canada and Newfoundland respectively, the first of them being about as large as the other two combined, they themselves being equal. On the walls are suspended more than five hundred horns and skulls, some of the former being the 'record', that is, the largest known for the particular animal. Among the horns shown is the magnificent pair of the Indian buffalo which were included in the Sir Hans Sloane collection received in 1753 and are prominent among the limited number of

zoological specimens which have lasted to our day. With the exception of a white giraffe which has been lent by Rowland Ward, Ltd., all the specimens are drawn from the Museum collections. They show to much greater advantage in their present setting than crowded together in glazed cases in the Mammal Galleries. The exhibit, which has been arranged by Capt J. G. Dollman, was opened to the public on May 31.

#### New Botanical Collections

THE Department of Botany, British Museum (Natural History), has received some noteworthy additions during the last two months. His Majesty the King has placed on permanent loan a further collection of Nepal plants presented to him by His Highness the Maharaja of Nepal. The present consignment numbers 253 specimens, which were collected by Prof K. Sharma, Major L. Dhwoj, who was responsible for the previous collections, died during the expedition. The value of the collection is that it is from previously unexplored mountains. Another collection which will add to our knowledge of the floristics of the Himalayan region has been presented by Capt F. Kingdon-Ward. It consists of 1233 specimens, and is from the Upper Irrawaddy and the Burma-Tibet frontier. A valuable addition is the gift of the Boswell-Syme British Herbarium by Mr. Frederick J. Hanbury. This contains about 20,000 sheets, in fourteen mahogany cabinets, and will be kept as a separate collection. Boswell-Syme (1822-1888) was the editor of the third edition of "English Botany", and the specimens on which his remarkably accurate descriptions were based are in the collection. The herbarium was purchased by Mr. Hanbury on Boswell-Syme's death, and is in excellent condition. British botanists will now be free to consult the remarkably long series of species which are rarely well represented in modern herbaria. Mr. A. Vernay has presented a set of plants obtained on the Vernay-Lang expedition to the Kalahari desert. This area is very poor floristically, and the 264 species, including twenty type gatherings, are consequently of value in extending our knowledge of distribution.

#### Acquisitions at the Natural History Museum

AMONG the chief recent acquisitions in the Zoological Department of the British Museum (Natural History) are 60 mammals and 590 birds obtained by the Vernay-Lang Expedition to the Kalahari Desert, presented by Mr. A. S. Vernay, the mammals include specimens of 11 forms recently described as being new to science by Mr. Austin Roberts of the Transvaal Museum. Another important gift received from Mr. Vernay is a collection of 184 mammals, 29 reptiles, 34 fishes, and 500 butterflies obtained by Capt Beresford Holloway, who accompanied Mr. Vernay on his recent expedition to the Malay Peninsula. This collection comprises many rare species, including a specimen of the rare *Rhinoceros sondaicus*, which is now being mounted, at the expense of the donor, for exhibition in the Museum. Purchases for the Department of Geology include a specimen of

the teeth of an extinct shark, *Edestus*, from Devonian rocks of Rhenish Prussia. The median teeth of *Edestus*, instead of falling away after use as in all other sharks, remained attached to their successors, forming in the course of time an external dental spiral which must have hung over the point of the jaws and sometimes contained no less than 150 teeth. Prof. G. Vibert Douglas has collected and presented to the Department of Minerals a large series of rocks illustrating the geology and mineralisation of several mines in the 'copper belt' of Northern Rhodesia and Katanga. Samples of volcanic dust which fell after the recent eruptions (April 11-12) in the Andes have been presented by the *Times* Publishing Co. and by Messrs H. W. Nelson, Ltd.

#### British Science Guild

AT the annual meeting of the British Science Guild held on May 25, Sir Samuel Hoare was re-elected president for the ensuing year, and affirmed his faith in the aims of the Guild. The annual report shows a year of useful work. Perhaps its most interesting feature is the attempt which the Guild is making, in conjunction with the Association of Scientific Workers, to provide an adequate channel for bringing before Parliament the views of scientific men. A Science Advisory Council is being set up, and it is intended that this Council shall be in some sense comparable with the Federation of British Industries, in the sense that it shall be the liaison body for providing contact with Parliament in connexion with scientific and technical matters coming before the House. The success of the projected Council will, of course, depend on the degree in which it enjoys the co-operation of scientific and technical societies, a number of which have already agreed to participate. The extent of its activities, however, will be mainly determined by that of the funds placed at its disposal, and in this aspect the matter has yet to be put on a satisfactory basis.

#### Research and Industry

IN a recent article in the *Journal of the Textile Institute*, on "Cotton Research and Academic Physics", Dr. F. T. Peirce points out that the tendency of men of science to get into ruts of thought is partly responsible for the tardiness of the academic mind to appreciate and interpret the problems of technology in a way that is essential for the interpenetration of science and industry. On the other hand, while as one consequence of specialisation every research worker is accustomed in his reading to slur over matter which he cannot or need not understand, the industrialist is apt to be offended if he encounters matter which is incomprehensible to him even though the practical conclusions are clear. Without claiming that scientific research is a complete cure for all the troubles of industry, Dr. Peirce urges that it is a method of securing the most effective use of available resources, and shows how, within the experience of the cotton industry, impersonal scientific methods have succeeded in saving efforts and resolving difficulties in the relations of firms or branches of the industry with

employees and between service departments Co-operation may ultimately lead the ideal of team work to merge in that of 'group work', groups having only their own ignorance or inefficiency as enemy, and in organisation by technical processes rather than by sciences

THE matter of publication is not without concern to the relations of science and industry, as pointed out by Dr Peirce, and a generous policy of publication for lines of pure scientific interest has a stimulating effect on the research staff from which the industry itself is the first to benefit. Publication assists in securing the recognition and interest from the universities, which are essential for open discussion, for combating the natural secretiveness of industry, and for creating a technical literature in which systematic cross reference becomes possible. These and other problems relating to the scientific reputation of the individual, the place of individual initiative and originality in co-operative research, are aspects of the relations between science and industry which are a modern phase of the conflict between authority and liberty. Much also remains to be done in redressing the present neglect of the borderland sciences, and cotton itself is of special interest in the borderland of physics. Finally, Dr Peirce suggests that by overcoming the technical difficulties of industry the scientific worker may remove obstacles to the development of beauty, and thus contribute to the artistic as well as to the humane aspect of industry.

#### Social Discontent and its Remedy

It is not altogether a new explanation of the social ills of the day to find a psychological rather than an economic explanation, but the theme is one that may well be stressed, and is ably expounded by Mr H. A. Bruce in a paper on "The Sources of American Discontent" (*Proc Amer Acad Arts and Sci*, vol. 67, No. 3, Feb. 1932). The social evils and discontent which Mr Bruce cites as being prevalent in America to-day are no less evident in many parts of Europe, and he finds the chief cause to lie in modern industrialisation, which not only narrows and starves the needs of the individual life, but also results in that crowding which leads to crowd mentality and all its drawbacks. The present state of affairs leads to discontent, adds to the prison population, the numbers of mental and nervous wrecks, and takes a mounting toll of suicides and lives shortened by bodily diseases promoted by mental stress. Mr Bruce admits the seriousness of the problem and the difficulties of solution when national policies are determined by majorities infused with the crowd spirit and on an arrested level of mental activity, but he makes the suggestion that the crowd spirit may itself be used to contribute to the acceptance of a wiser philosophy of life than is summed up in making money, spending money, and amusing oneself. Intensive education of a far-spreading kind is the agency to apply in changing the outlook of industrialised peoples, and leading them to an appreciation of values other than those which prevail to-day.

#### Hydrogen and its Uses

DR E. F. ARMSTRONG recently delivered a lecture on hydrogen and its uses before the Royal Society of Arts (*J Roy Soc Arts*, May 6). Two important methods of preparation of hydrogen are from water gas and coke oven gas. The carbon monoxide in water gas is oxidised to carbon dioxide by passing a mixture of the gas and steam over a catalyst containing iron oxide, the hydrogen of the reacting steam being set free. The small residue of carbon monoxide is removed by absorption under 200 atm pressure. The preparation from coke oven gas depends on purification by washing and fractional cooling, whereby first the methane and then the carbon monoxide is removed. The cost of production by either method under the most favourable conditions is about 1s per thousand cubic feet of hydrogen. The principal uses of hydrogen are for the hydrogenation of fats, in which liquid oils are converted into solid fats by taking up hydrogen in the presence of small quantities of nickel, the hydrogenation of other organic materials, including mineral oil, tar, and coal, and the production of synthetic ammonia. The conversion of coal into oil by treatment with hydrogen under pressure involves the use of an elaborate and costly plant, and so far as the production of petrol is concerned, the cost is put down at 7d-8d per gallon, as compared with a price of less than 2d per gallon at the oilfield. The prices may alter in future in favour of petrol from coal. If hydrogen is ever required in larger quantities by the oil industry, it could be obtained from the methane of natural gas or refinery waste gas, which readily reacts with steam to form hydrogen and carbon dioxide.

#### The National Physical Laboratory

THE Report of the National Physical Laboratory for the year 1931 is an illustrated quarto volume of 131 pages (London: H.M. Stationery Office, 15s. net). As usual, it gives a readable and interesting account of the progress of the work of each department without introducing technical details, and equally as usual, that progress must be gratifying to the Board and to the staff. The new physics building is now in use and the old quarters of physics are occupied by electrical standards. The compressed air tunnel building is completed, the new tank will be completed this year, and the new acoustics building has been commenced. Dr W. Rosenhan has left to take up other work, Prof C. H. Desch of Sheffield succeeds him, while Dr W. E. Dye has been lost by death. Ninety-seven official papers by members of the staff have been published during the year in the scientific or technical journals or in the proceedings of societies. We note the determination of the yard and metre in terms of the wave-length of the red cadmium line, the accurate measurement of time for radio frequencies, and an international agreement as to colour standardisation. Routine tests of almost all types have, with few exceptions, decreased. In the watch tests, the success of one Swiss firm is very remarkable.

### Land Conditions in Iraq

SOME valuable information regarding the irrigated and non-irrigated land in Iraq is contained in a report by Sir Ernest Dowson on "Land Tenure and Related Questions" (Baghdad Iraqi Government, 4s 6d). These statistics, which are shown also on large scale maps accompanying the report, were collected by the Irrigation Department, and show the immense possibilities for the extension of agriculture when conditions are favourable. It would appear that about twenty per cent of the total area of Iraq can be regarded as productive. This includes a northern rainfall zone covering about nine per cent, and a southern irrigation zone covering about eleven per cent. Not more than a fifth, and often as little as a tenth, of these zones are cultivated in any one year. An estimate of the rural population, for which complete accuracy is not claimed, puts the density of population so low as 19 per square kilometre in the rainfall zone, and about 35 in the most typical areas of the irrigation zones. These figures, especially the latter, are far below the potential population of the land, and compare unfavourably with the far greater density of population and higher productivity of similar lands in Egypt. Sir Ernest Dowson also comments on the lack of accurate topographical surveys in Iraq and the incompleteness of even the major triangulation. The report contains various recommendations regarding methods of land tenure, and naturally stresses, in this connexion, the need of further surveys.

### The Harpy at the London Zoo

OF the two well-known and remarkable neotropical birds of prey, the condor is a familiar menagerie exhibit, but the harpy always rare. The specimen the London Zoological Gardens has recently received being only the third exhibited during this century, although the species was shown early in their career. Although commonly called an eagle from its large size, the harpy is in form, coloration, and habits a giant goshawk, allied to the tropicopolitan group of hawk-eagles (*Spizaetus*). Like these, it presents the remarkable peculiarity of showing much more white in the immature plumage than in that of the adult, in fact, the present specimen, in its gull-like livery of white and grey, is curiously like a very different bird which is lodged next door to it in the Birds of Prey Aviary—the East Asiatic and Australasian white-bellied sea-eagle (*Circus leucogaster*). The ruff and crest of the harpy, however, give it a character quite unique among the Falconidae, and it is this species, rather than the golden eagle, which is the analogue of the lion among beasts, especially as its feet and talons are unrivalled for size and power in the whole series of birds of prey.

### A 'Deaf Speaker'

A NEW device which will aid the deaf to hear radio and gramophone music has been invented by Prof. F. Bedell, the well-known physicist of Cornell University. He calls it the 'deaf speaker' because it serves a function similar to a 'loud speaker' in a radio set. It does not broadcast sound, but carries vibrations of

the requisite amplitude and frequency to anyone who holds the receiving part of the apparatus with his teeth or pressed against his forehead or a cheekbone. From a summary of a radio talk reported by Science Service of Washington, D.C., on May 5, we learn that Prof. Bedell, working on the theory that most people who hear badly have a defective middle ear, sought to bring the sound waves to the inner ear by some other channel. He found that it could be done by bone conduction to the inner ear of the listener. It was not sufficient to transmit vibrations of the same frequency as the actual sound waves to the inner ear of the listener. They must first be adjusted to the requisite loudness and frequency. It is stated that this adjustment is substantially what takes place in the normal middle ear. Prof. Bedell's deaf speaker steps up the force of the sound waves very appreciably. Since some people are deaf to high tones and others cannot hear lower tones, the deaf speaker is provided with a device for altering the frequency. At a recent demonstration at the National Academy of Sciences, Prof. Bedell showed two kinds of receiving instruments, in one of which the receiver is held between the teeth and looks like a long tube, while the other consists of a flat disk held against the forehead or a cheekbone. The disk type has made it possible for deaf people with the aid of a microphone to hear their own voices. This apparatus is said to be very useful for teaching the deaf. It is portable, but is rather too large for everyday use.

### Earthquake in the Western Pacific

A STRONG earthquake occurred in the western Pacific on the morning of May 14. Its records were confused with those of another earthquake in the West Indian region, but the position of its epicentre has now been determined with the arrival of additional records from seismological stations surrounding and in the Pacific. It lies in about lat. 4° N, long. 130° E, as determined by the seismologists of the U.S. Coast and Geodetic Survey (Wire Report of Science Service, Washington, May 16). This point lies at sea, south-east of the island of Mindanao in the Philippines. The earthquake was clearly a severe one, as it is reported to have been felt distinctly to a distance of about 600 miles from the epicentre.

### Congress of Quaternary Geology

A MEETING of the Association for the Study of the European Quaternary will be held in Leningrad on Sept. 1-7. There will be two short excursions during the Congress and a long excursion from Sept. 8 until Sept. 29. Special arrangements have been made by the organising committee for the reception of members, and it is requested that geologists, archaeologists, and others who wish to attend should send in their names to the Secretary, Mr. K. Lebedev, V.O. Sredny Pr., 72-6, Leningrad 26. Particulars relating to the Congress, with programme of excursions, etc., can be consulted in the Library of the Museum of Practical Geology, 28 Jermyn Street, London, S.W.1, or at the Office of Intourist, Bush House, Aldwych, W.C.2.

## Announcements

PROF W A BONE, professor of chemical technology in the Imperial College of Science, will deliver the Bakerian Lecture before the Royal Society on June 9, taking as his subject "The Combustion of Hydrocarbons"

At the anniversary meeting of the Linnean Society of London held on May 24, the following officers were elected *President*, Prof F E Weiss. *Treasurer*, Mr F Druce, *Botanical Secretary*, Mr J Ramsbottom, *Zoological Secretary*, Lieut-Col J Stephenson. The Linnean Gold Medal was presented to Prof E S Goodrich

THE second conversazione of the Royal Society this year will be held in the rooms of the Society on Wednesday, June 22

At the annual general meeting of the Institute of Physics held on May 24, the following were elected to take office on Oct 1 next *President*, Lord Rutherford, *Honorary Treasurer*, Major C E S Phillips, *Honorary Secretary*, Prof A O Rankine. The other vacancies on the Board were filled by the election of Prof H S Allen and Dr C V Drysdale as vice-presidents, and Mr R A Watson Watt and Mr D Orson Wood as non-official members. Sir Frank Dyson and Sir William Bragg were elected honorary fellows of the Institute

From the interest derived from the invested capital of the Sir George Beilby Memorial Fund, at intervals to be determined by the administrators representing the Institute of Chemistry, the Society of Chemical Industry, and the Institute of Metals, awards are made to British investigators for distinguished original work in science, preference being given to investigations relating to the special interests of Sir George Beilby, including problems connected with fuel economy, chemical engineering, and metallurgy. Applications must reach the Convener, Sir George Beilby Memorial Fund, Institute of Chemistry, 30 Russell Square, London, W C 1, not later than June 14

THE eighty-fifth annual meeting of the Palaeontographical Society was held in the rooms of the Geological Society, Burlington House on May 27, Dr F L Kitchen, vice-president, in the chair. The report announced the completion of the monograph of fossil Macrurous Crustacea, by Mr Henry Woods, and recorded the publication of further instalments of the monographs of Corallian Lamellibranchia, Gault Ammonites, and Cambrian Trilobites. During the year, the Society received a small bequest from the estate of the late Dr Charles W Andrews. Mr L R Cox, Prof A Morley Davies, Prof W B R King, and Mr H Woods were elected new members of council, and Dr F A Bather, Mr Robert S Herries, and Sir A Smith Woodward were re-elected president, treasurer, and secretary respectively

THE Institute of Physics announces that the British Optical Instrument Manufacturers' Association (B O I M A) Prize for the best paper published in the *Journal of Scientific Instruments* during the year 1931

is to be equally divided between Mr H C H Townsend, of the National Physical Laboratory, for his paper on "A Daylight Factor Integrator", and Prof E W Marchant, Mr J K Burkitt, and Mr A H Langley, of the University of Liverpool, the joint authors of the paper, "A Portable String Galvanometer for use at Moderate Frequencies", and the Institute of Physics Prize for the best contribution to the laboratory and workshop notes in the *Journal* has been awarded to Mr F W Kirkby, of the Royal Aircraft Establishment, Farnborough, for his note, "Improved Method of holding Mirrors for Sextants and other Instruments"

THE next series of eight lectures and demonstrations at the London School of Hygiene and Tropical Medicine on tropical hygiene, for men and women outside the medical profession proceeding to the tropics, will be given by Lieut-Col G E F Stammers on June 14-23. Particulars can be obtained from the Secretary of the School, Keppel Street, Gower Street, W C 1

APPLICATIONS are invited for the following appointments, on or before the dates mentioned—A temporary assistant teacher of nautical subjects at the Nautical School and School for Fishermen, Boulevard, Hull—The Education Offices, Guildhall, Hull (June 11). A University reader in education at the Institute of Education (incorporating the London Day Training College)—The Academic Registrar, University of London, South Kensington, S W 7 (June 13). Evening teachers in fitting and machining and workshop processes and planning at the Wandsworth Technical Institute—The Secretary, Technical Institute, Wandsworth (June 13). A full-time lecturer in civil engineering in the Building Department of Rutherford Technical College—The Director of Education, Education Office, Northumberland Road, Newcastle-upon-Tyne (June 13). An assistant instrument maker in the Department of Physiology of University College, Cardiff—The Registrar, University College, Cathays Park, Cardiff (June 15). A professor of bacteriology in the University of Durham College of Medicine, Newcastle-upon-Tyne—The Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne (June 18). A lecturer in the chemistry department of the Heriot-Watt College, Edinburgh—The Principal, Heriot-Watt College, Edinburgh (June 20). An assistant master at the Mining and Technical Institute and Boys' Junior Technical Day School, Neath, with the qualifications of an industrial chemist and possessing a degree in applied science, including metallurgy—The Director of Education, County Hall, Cardiff (June 21). A professor of medicine in University College, Galway—The Secretary, University College, Galway (June 30). Junior assistants under the directorate of explosives research, and a junior assistant under the directorate of ballistics research, of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S E 18. A full-time junior teacher for engineering subjects at the Oldham Municipal Technical College—The Director of Education, Education Offices, Oldham

### Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

#### Eland-Ox Hybrid

THE crossing of the eland and domestic cattle has been reported fairly frequently, and some years ago several cases were alleged in Southern Rhodesia. After a prolonged correspondence (1923), in which assistance was given by the local magistrate, the late Mr W Farrer, it was concluded that the reported hybrids were not authentic. The owner stated that they were almost indistinguishable from domestic cattle, and the fact that tame bull elands will readily serve domestic cows seemed a sufficient explanation of the alleged hybridism.

FIG 1—Bull eland, Afrikaner cow, and hybrid calf, Malpas Farm, Orange Free State

At the Government Experimental Farm at Cedara, Natal, attempts at crossing have had no result.

It would appear, however, that a successful cross has now been obtained (March 1932) at Malpas Farm, owned by Mr R E Helme, Westminster, Orange Free State, under conditions which would seem to preclude any possibility of doubt. On this farm there were half-a-dozen Afrikaner cows, but no bull of any description, except a bull eland which had been obtained from the Zoological Gardens, Pretoria, some three years ago, and this animal had been bred in the Gardens. Mr Helme, who is a Cambridge graduate and a scientific man, assures me that he has no doubt whatever as to the paternity of the male calf, and in a personal letter states, "It looks extraordinarily like an Afrikaner. The chief points of difference are the small pointed ears, slender limbs, heavy dewlap and a fawn colour mark on the side" (Fig 1).

The rhinarium would appear to be like that of the ox, but there is some development of the dorsal hump of the eland.

It is, of course, doubtful if the hybrid will prove fertile, but the cross is of considerable scientific interest, since the eland is really very different from the genus *Bos* in many important anatomical characters—and, so far as I am aware, a successful cross be-

tween two mammalian species of different genera has not previously been recorded.

From the general aspect of the young calf it would appear that the *Bos* characters will be markedly prepotent over the eland characters.

In this connexion it would be interesting to ascertain as to how far the chromosome complex of the eland differs from that of domestic cattle, but I do not know if any observations have been made even on the latter.

Pietermaritzburg,  
April 12

ERNEST WARREN

#### Origin of Insects from Crustacea

THE problem of the origin of insects has for long remained unsolved. In recent years, interest in it has considerably increased and I have myself brought forward arguments<sup>1</sup> which, while still admitting the possibility of a descent from Crustacea, tend rather to the view that insects and Crustacea have no very close relationship.

The supporters of the theory of a crustacean origin for insects rely chiefly upon the attempt to prove that the insect leg was originally a biramous appendage of the type found in the Malacostraca, in other words, that it originally possessed a true exopodite as well as an endopodite (the main shaft of the leg). It has long been known without a shadow of doubt that the lobes of the insect maxillæ are merely endites or gnathobases developed from a uniramous stalk. The only structures which can reasonably be claimed to be exopodites are the *coxal styles* found on the middle and hind legs of the family Machilidæ. These styles closely resemble the *abdominal styles*, found in Machilidæ and other Thysanura, and believed to form part of the reduced abdominal appendages.

So far as I know, nobody has ever succeeded in hatching any Machilid from the egg or in otherwise dis-

covering the first instar of these insects. Heymons once stated (1897) that the abdominal styles of *Lepisma* did not appear until after the insect had hatched from the egg, but he was silent about the coxal styles of *Machilis*.

The position has become something of a 'stalemate', and further argument has appeared to me useless until such time as the first instar of a Machilid could actually be discovered. I have, therefore, fixed my attention on this point for the past two years. Thanks to the co-operation of Mr Royce Cannon, a student of the University of Queensland, success has at last been attained. Machilidæ are very rare insects in Australia, but Mr Cannon succeeded in discovering a locality near Brisbane where, amongst deep rubble and decaying leaves below a sheltered wall of rock, a species of *Allomachilis* could always be found. He has recently sent me specimens of the first, second, and many subsequent instars. I am now able to state definitely that this insect hatches from the egg with its abdominal styles fully formed, but *without any sign of coxal styles*. The second instar, like the first, is devoid of coxal styles, and it is only in the later instars that these organs are formed. At no time do they possess muscles, whereas the abdominal styles are provided with muscles from the very start.

We are, therefore, justified in concluding (1) that the abdominal styles are *not* serially homologous with the coxal styles in Machilidae, (2) that the abdominal styles are parts of the original embryonic appendages, and (3) that the coxal styles are certainly *not* parts of such original appendages, but are merely

FIG 1—*Allomachilis* sp., Brisbane, Queensland. A Middle leg, first instar. B Middle leg, from specimen two-thirds grown. cx, coxa, fm, femur, st, coxal style, t, tendon of claw, tb, tibia, tr, trochanter, ts, tarsus (unjointed in A, three-segmented in B). A,  $\times 40$ , B,  $\times 75$ .

secondarily developed *spurs* without any muscle supply and having a deceptive resemblance in form to the abdominal styles.

For the benefit of those interested in the general problem, I append herewith a table showing the correct interpretation of the various limb processes in insects which, at one time or another, have been claimed by supporters of the theory of crustacean origin of insects to be true exopodites.

| Appendages                              | Process claimed to be Exopodite                 | Correct Interpretation                                                                                                                                                                   |
|-----------------------------------------|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| First maxillæ                           | Lacinia                                         | Endite (Gnathobase)                                                                                                                                                                      |
|                                         | Galea                                           | Endite (Gnathobase)                                                                                                                                                                      |
| Second maxillæ                          | Glossa                                          | Endite (Gnathobase)                                                                                                                                                                      |
|                                         | Paraglossa                                      | Endite (Gnathobase)                                                                                                                                                                      |
| Middle legs                             | Coxal style (Machilidae only)                   | Coxal spur without musculature                                                                                                                                                           |
| Hind legs                               | Coxal style (Machilidae only)                   | Coxal spur without musculature                                                                                                                                                           |
| Gonapophyses of ninth abdominal segment | Inner valve (female) (Claimed by Crampton only) | Either (a) telopodite (endopodite), the dorsal valve then being the limb-base carrying a style, or (b) secondary process of the limb-base, the style representing the reduced telopodite |
| Cerci                                   | Paraproct (Claimed by Crampton only)            | Secondary outgrowth of the eleventh sternite, <i>not</i> part of an appendage, the cerci being the complete appendages of the eleventh segment                                           |

I think the accompanying table shows conclusively that there is now not a shred of evidence left, from a consideration of the appendages, that insects were ever derived from ancestors possessing biramous limbs of the Malacostracan type. That being so, it

seems to me that the theory of the crustacean origin of insects is now effectively disposed of, and attention should be directed to more promising lines of inquiry.

### Nuclear Spin of Phosphorus from the Band Spectrum

THE extensive band system of  $P_2$  in the ultra-violet is easily produced with considerable intensity by an uncondensed discharge through pure phosphorus vapour contained in a quartz tube. Regularities in the frequencies of the band heads were first found by Geuter, but the correct quantum designation of the bands has only recently been established by the work of Jakowlewa<sup>1</sup> on the absorption and fluorescence of the more refrangible part of this system. Two years ago, Herzberg reported, in a letter to NATURE, that a sudden breaking off occurs in the band progressions associated with various upper vibrational levels (at  $v' = 11$  with the present assignment of vibrational quantum numbers), which can only be attributed to predissociation<sup>2</sup>. Herzberg also found that the rotational lines of the bands of highest observed  $v'$  stop suddenly, as was to be expected in consequence of the predissociation.

Since an alternation of intensity in the band lines should be observed in the spectra of molecules composed of two like atoms, provided the nuclear spin is finite and not too large, we have obtained high-dispersion spectrograms of the  $P_2$  bands in an attempt to detect this. Although no alternation has been mentioned by previous investigators, our plates showed clearly that the intensities alternate in a ratio which we estimated at 3:1 in our first report on this work<sup>3</sup>. Since then, we have obtained better plates in the second order of a 21-foot grating, and carried through the analysis of the rotational structure by means of the combination principle. The newer results leave no doubt that the alternation of intensities is real, and that the nuclear spin of the phosphorus atom must be  $\frac{1}{2}$ , as required by the

alternation ratio of 3:1. Quantitative intensity measurements, which are now in progress, will almost certainly confirm this. Furthermore, we find that the odd numbered rotational levels ( $K'' = 1, 3, 5, \dots$ ) of the lower state have greater statistical weight, and since this state is  $^1\Sigma_g^+$ , like the normal state of nitrogen, the complete wave-function of the molecule must be antisymmetrical,  $A_n$ , and the nuclei obey the Fermi-Dirac statistics.

A great many of the bands in the longer wavelength part of the spectrum, which can be studied with the grating, show marked perturbations of the rotational structure. Some of those which are sufficiently regular to yield reliable values of the band constants have been measured, including the following: 6,22 ( $\lambda$  head 2970.75), 6,23 (3028.00), 8,27 (3166.14), 8,28 (3228.65), and 9,28 (3183.84). From these we find, as preliminary values  $B_v'' = B_v' - a(v' + \frac{1}{2}) = 0.3045 - 0.00152(v' + \frac{1}{2})$ ,  $B_v' = 0.2410 - 0.00165(v' + \frac{1}{2})$ . The value of  $B_v''$  gives the moment of inertia of  $P_2$  in its normal state as  $90.8 \times 10^{-40}$  gm cm<sup>2</sup>, and the internuclear distance,  $r_v'' = 1.88 \times 10^{-8}$  cm. The latter figure is unexpectedly large, if we compare it with the  $r_v''$  of  $S_2$  ( $1.603 \times 10^{-8}$  cm) and with that predicted by Morse's empirical rule ( $1.5 \times 10^{-8}$  cm). There is no ambiguity, however, in the determination of our values of  $B_v$ . The bands are of the simple  $^1\Sigma, ^1\Sigma$  type, consisting of singlet

*P* and *R* branches, and only one assignment of rotational quantum numbers fulfils the combination principle exactly. Our conclusion as to the type of electronic transition involved agrees with that reached by Herzberg<sup>4</sup> as the result of unpublished work. A cursory examination of the breaking off of the rotational structure for bands with  $v''=10$  and 11 also confirms his statements in this connexion. We do not propose to investigate the detailed effects of predissociation in this spectrum, as we understand that Dr Herzberg is continuing his work in this phase of the problem.

### Disintegration of Atomic Nuclei

THE epoch-making results as to the disintegration of atomic nuclei recently obtained in the Cavendish Laboratory serve to recall the experiments of Prof J N Collie and his fellow-workers made twenty years ago. In some of these experiments it was thought that helium and neon were produced by sending powerful electric discharges through exhausted tubes. Sir William Ramsay observed the presence of helium in an old X-ray tube. Little information is available in the published accounts as to the potential difference employed in the experiments or as to the previous history of the (aluminium) electrodes. It was generally supposed that the balance of evidence was against such transformations, but it is possible that the failure of other investigators to reproduce the results of Collie may have been due to the fact that the precautions which they took resulted in an insufficient supply of swift protons in the discharge tube.

Be that as it may, taking into consideration the old and the new experiments, I should like to suggest that the aluminium nucleus, for example, may yield neon on disruption, in accordance with the process

In his report<sup>1</sup> of the discussion on the structure of atomic nuclei at the Royal Society, Dr Ellis emphasises the uncertainty in speculating about such processes as

but, in view of the possibility of the nucleus being built up of shells in a fashion somewhat resembling the electronic structure of the chemical atom, the suggestion that the neon nucleus is present in aluminium seems worthy of consideration.

In the second place, I should like to enter a caution as to accepting the particles of mass unity discovered by Dr Chadwick in beryllium 'radiation' as representing the ultimate neutron. In a paper<sup>2</sup> on quantum magnetic tubes in rotation, published in 1925 and described in my book on "The Quantum and its Interpretation", I developed a suggestion due to Prof E T Whittaker, that the difference between positive and negative electric charges might be interpreted as arising from different directions of rotation of the tubes. In the admittedly crude model there described, the mass of the neutron, in which there is no rotation of the tubes, would be the arithmetic mean of the masses of the proton and the electron. It therefore seems possible that the corpuscle of mass unity is composed of two neutrons. For, according

to the hypothesis mentioned, the neutron is a magneton, and magneton pairs are likely to occur. Electron pairing is now recognised as an important factor in molecular structure, and may be attributed to the magnetic properties of the electron.

Experiments in an inhomogeneous magnetic field may serve to show that the corpuscles of Dr Chadwick possess a magnetic moment, but probably the magneton pair would constitute a neutral magnetic system of small magnetic moment. Further search might be made for particles of about half the observed mass and possessing a magnetic moment.

### Oscillations of the Methane Molecule

FROM a consideration of the infra-red absorption data, Dennison<sup>1</sup> assigned 1304, 1520, 3019, and 4217 as the fundamental frequencies of the methane molecule, the highest, 4217, representing a symmetric expansion of the tetrahedron. In the Raman spectrum of methane, however, 4217 fails to appear, and we have instead a frequency 2918 recorded as an intense and sharp line, which is inactive in infra-red absorption and is therefore to be identified with a symmetric oscillation of the tetrahedron. I have accordingly suggested in a recent paper<sup>2</sup> that the fundamental frequencies of methane are 1304, 1520, 2918, and 3019, the frequency 4217 being merely a combination of the first and the third fundamentals.

Striking evidence in support of the new assignment is now forthcoming from observations made by me on the state of polarisation of the Raman lines. It is found that 2918 is nearly completely polarised ( $\rho=0.08$ ), whereas the line 3019 is nearly unpolarised ( $\rho=0.8$ ), thus presenting a complete analogy with the state of polarisation already ascertained for the third and fourth fundamentals in the case of the tetra-chlorides. It is interesting to note that in the Raman spectra, 3019 appears accompanied by vibration-rotation components, while the more intense 2918 fails to exhibit them.

### Swarming of Collembola in England

THE swarming of certain species of Collembola has been previously noted in Europe by several authors, notably Nicolet,<sup>1</sup> Low,<sup>2</sup> Linnaniemi,<sup>3</sup> Latzel,<sup>4</sup> and Handschin,<sup>5</sup> and more recently J M Brown,<sup>6</sup> in a paper in the *Naturalist* for 1921, recorded several instances of this occurring in the north of England. The species in which he observed this phenomenon were *Podura aquatica* L., *Hypogastura viatica* (Tullb.), *Hypogastura purpurea* (Lubb.), *Anurida maritima* Lab., *Isotomurus palustris* (Mull.), *Sminthurides malmgreni* var. *elegantula* Reut., *Sminthurinus aureus* var. *ochropus* Reut. All except the *Sminthurinus* and *Hypogastura purpurea*, which were found on an old stone wall, are recorded as occurring on water.

In January this year I found two instances of the swarming of *Onychurus armatus* (Tullb.). On Dec 4, 1931, considerable numbers, mostly of the adult form of the species, were noted in a heap of dead leaves in a garden in Balham. By Jan 18, 1932, the numbers

had greatly increased, so that parts of the heap were covered over with a creamy-white layer of the insects. The swarm was at the time composed of a very high percentage of immature forms. From about two cubic inches of mould I obtained some 130 individuals. The species is one which, as Brown observes, is known to be gregarious in its habits, but this is, I believe, the only recorded instance of its swarming.

Two other instances of this phenomenon were witnessed in the London area in the late autumn of 1931. The first of these was the occurrence of large numbers of *Hypogastura viatica* (Tullb.) on a small pool of stagnant water on Wimbledon Common in October. They appeared in such numbers as to form a black band to a width of one foot or more around the margin of the pool. This swarm was composed almost equally of adult and immature forms. The second of these two likewise occurred on Wimbledon Common. In September 1931 great numbers of *Sminthurus viridis* (Linn.) were seen on an old wooden post which, although only 4 ft high, had on its surface several hundred individuals, one side being almost completely covered.

In most of these cases of swarming (if not all) the factor producing this phenomenon would seem to be the relative abundance of the food supply. It may be supposed that an exceptionally suitable food supply of small extent and, in the case of winter breeding species like *Onchururus armatus*, a spell of mild weather, increases the reproductive activities of the species, resulting in large numbers of immature forms which on a habitat of limited extent cause the appearance of the swarm. Other explanations of this swarming of *Collembola* would seem to be those of migration, as suggested by McNamara,<sup>7</sup> or possibly the sudden cessation of controlling influences. This last may perhaps go some way towards accounting for the swarming of *Sminthurus viridis* recorded above, as Lubbock<sup>8</sup> states that it is attacked by a small red mite which if fairly numerous in any locality might become a controlling factor of a very potent kind.

It is a significant fact, and one having some bearing on explanations, that all the species in which swarming has been recorded are gregarious.

### Internationalism and Science

WHEN in South Africa last year, I tried to understand the politics of that country, turning largely on the differences between the British and the Dutch South Africans. Discussing the relative merits of two great South African leaders, I was told that one stood for the Empire, the other for South Africa, or that one was a practical politician, the other was not. But the substance of the matter seemed to be this, that one was predominantly intellectual, the other predominantly emotional. Now, when crossing the ocean, I much prefer a captain who guides the ship by means of his intellect, to one who does it by his emotions. We can scarcely think otherwise of the ship of State. Yet the emotions are very precious to us all, and to a very great extent we live by and for them.

Science, belonging to the intellectual sphere, must from its very nature be international. The scientific fraternity is the true International. But the emotional part of our nature is necessarily personal, or local, or national, rather than international. The arts serving our emotional needs should be similarly personal or local, and when they lose that quality they often deteriorate.\* A very good example is the world fashion in clothing, causing 'well-dressed' young women to appear alike, whether in Central Asia or South America. On this basis we can understand why the Dutch South Africans cling to their peculiar language, a thing at first appearing so perverse and so useless. They do not wish their 'culture', the emotional side of their nature, to be submerged by the tide of Anglo-American 'civilisation'. I will not say that this justifies the use of Afrikaans in South Africa or Irish as the standard language of Ireland, but at any rate the motive has a genuine basis in the desire to preserve something of value.

In the field of religion we have a similar conflict. The Churches serve as an outlet for the emotional nature of man on a high plane, and are in that sense a necessity for his well-being. But on the intellectual side they offer us a conflict of doctrines having a traditional basis, which for the most part wither away when exposed to the light of modern science.

The general outcome is this, that science is and must be the leading international cult, and must be our guide in the practical affairs of life. But scientific men must recognise the limits of internationalism on the emotional side, and the positive disadvantage of trying to make all people *feel* alike. Thus the British should adopt and absorb everything of value in American science, but would be quite justified in excluding the American cinema, which tends to create an emotional attitude which is not British, or at any rate not in accordance with the ideals on which the future of Britain should be established. I recently heard a very able speaker, just returned from Europe, discuss what the students of Europe *think*. His discussion was very illuminating, but he was principally describing what they *feel*. That they should feel keenly and ardently is well enough, but it is dangerous to the public peace when they have only *felt*, but imagine themselves to have *thought*. To separate these two great functions of the mind, and give each its proper place, appears to be fundamental for human progress on sound lines.

### Stokes's Formula in Geodesy

I QUITE agree with the opinion expressed by Mr. Gulattee of the Survey of India<sup>1</sup> that Stokes's formula for the elevation of the geoid above the spheroid of reference is rather sensitive to systematic errors in gravity. The proper course seems to be, however, not to abandon Stokes's formula but to try to rid of error the reduced values of gravity, so that the results of applying the formula may be trusted.

The reason for this statement is that Stokes's formula furnishes the only known method—accurate or not—for obtaining the absolute elevations of the geoid referred to the spheroid without making some hypothesis as to the distribution of densities within the earth. The deflexions of the vertical can, in the nature of the case, give relative elevations only. Further—

more, until we can perform at sea operations equivalent to our triangulation and astronomical measurements on land, Stokes's formula furnishes the only means of obtaining the distance between the geoid and the spheroid over the oceans, that is, over nearly three-quarters of the area of the globe, unless again we resort to hypothesis. For example, the geoid may be computed for any region, whether on land or sea, by assuming a definite theory of isostasy. Interesting specimens of the contours of the geoid computed on the theory of isostasy may be found in the "Geodetic Reports of the Survey of India", vol 5, and in the *Geophysical Supplement to the Monthly Notices of the Royal Astronomical Society* (vol 3, No 1, Jan 1932).

Even with the admitted sensitiveness to the effect of error in reduced values of gravity, and with the consequent uncertainty in the geoid heights, the formula may be accurate enough to give valuable information about certain geophysical questions to which even a rough answer may be of value. For example, is the geoid over the deeper parts of the oceans depressed below the spheroid of reference, as the theory of isostasy would require, or is it raised above the spheroid, as certain observations of gravity at sea, admittedly too few to be conclusive, would seem to suggest? Is the form of the geoid more nearly a triaxial ellipsoid than an ellipsoid of revolution? Or more accurately stated, does the ellipsoid most nearly representing the earth as a whole deviate from an ellipsoid of revolution sufficiently for the deviation to have substantial geophysical significance?

Of course, as Mr. Gulattee suggests, Stokes's formula may be useful for determining relative or differential elevations of the geoid above the spheroid. It seems to me, however, that in regions where triangulation and astronomical observations are available the deflexions, as determined from these, ought to give a better idea of the differential elevations from Stokes's formula. The main value of the latter is for absolute elevations.

#### Errors in Thermal Measurements

PROF. PARTINGTON directs attention<sup>1</sup> to errors which are likely to be present when resistance thermometers are used in measurements of heats of adsorption. He does not refer to thermocouple thermometers directly, but he includes in his references papers which describe their use. Although calorimeters in which such thermometers are used are far from perfect, the situation is not quite so black as his letter might lead one to believe. For example, results have been obtained with these thermocouple calorimeters which agree with those of the ice calorimeter.<sup>2</sup>

The nature of the errors met with in measurements of heats of adsorption depends to some extent on the type of adsorption studied. Where adsorption is very rapid, care must be taken that the following conditions hold. It is essential that (a) the calorimeter be completely surrounded with objects at a constant temperature, (b) that the gas be admitted to the centre of the adsorbent and not to the sides of the mass, and (c) that sufficient length of the thermocouple leads be immersed in the adsorbent. (a) and (c) can be tested by the admission of an inert gas which will change the temperature in the neighbourhood of the junction

unless the enclosure is at constant temperature, or if appreciable quantities of heat are conducted away by the thermocouple leads outside the calorimeter. When such precautions are taken, no maxima are obtained on the differential heats of adsorption curves similar to those recorded in results of earlier work.<sup>3</sup> When a high vacuum is obtained after adsorption, as is the case for the adsorption of oxygen on charcoal, the rate at which heat is distributed throughout the calorimeter is slow. In this case, it takes two to five minutes before the rate of cooling obeys Newton's Law. This causes an uncertainty in the value deduced for the heat of adsorption of not more than 5 per cent, and in some cases the error may be much less than this.

Where adsorption is not very rapid, (b) is an unnecessary precaution.<sup>4</sup> Since adsorption is slow, it is, however, necessary to make continuous measurements of pressure and temperature simultaneously in order that suitable corrections can be made to the cooling curves. In such cases, however, since adsorption usually occurs at high pressures, the thermometric lag is generally small.

The development of thermocouple calorimeters for measurements of heats of adsorption is of importance since these afford the best means of measuring these values at temperatures other than room temperature.

#### Free Ethyl

THE demonstration by Paneth and his collaborators of the existence first of the methyl<sup>1</sup> and quite recently of the ethyl<sup>2</sup> radicals in the free state has not, so far as we are aware, received independent confirmation. As apparatus capable of giving high streaming rates at suitable pressures being available in connexion with other researches which are engaging our attention in these laboratories, it appeared of interest to repeat the thermal dissociation of lead tetraethyl.

The material supplied by British Drug Houses was fractionated in a vacuum before use, and the operations were carried out in hydrogen, especial precautions being taken to ensure the absence of oxygen and moisture in the gas or on the surface of the apparatus. The velocity of the gas stream was 7.5 metres per second at pressures varying from 1.3 mm through the transparent silica tube of 6 mm internal diameter in which the phenomena were observed. So far as they went, our results confirm entirely the experiments of Paneth and Lautsch,<sup>2</sup> namely (1) the removal of lead mirrors was readily detectable 10 cm away from the source of the aggressive agent, (2) there was reformation of material which in turn yielded a mirror on heating, (3) an approximate measurement of the life period gave a result of the same order as that found in the original experiments.

### Carbon Monoxide from Carbonates

IN the course of an investigation of the stability of certain ketylic derivatives we have found that carbon monoxide is produced in quantitative yield through the interaction of metallic sodium with certain non-polar carbonates. Thus, sodium reacts readily with a warm xylene solution of diphenyl carbonate with the formation of sodium phenoxide and carbon monoxide, as indicated by the following equation

The evolution of carbon monoxide proceeds quite smoothly and the gas is obtained in a state of high purity. In fact, the reaction is well adapted for the laboratory preparation of pure carbon monoxide. It is also interesting to note that the gas as thus prepared is so dry that it does not explode on 'sparking' with dried oxygen.

The above reaction also occurs with alkyl carbonates, such as ethyl carbonate.

We have obtained evidence to show that the reaction occurs through the intermediate formation of ketylic derivatives. The dimeric forms of these derivatives, containing the phenoxy group, are unstable and suffer rapid decomposition with the elimination of sodium phenoxide. On these premises, it is interesting to note that the immediate precursor of carbon monoxide is the unknown oxide,  $\text{C}_3\text{O}$ .

Work along these lines is in progress in this laboratory, and further details will be published elsewhere.

### Electrostatic Explanation of the Phenomenon of Flotation

PROF KAMIENSKI suggests<sup>1</sup> that the adsorption of certain organic substances at the surfaces of platinum, graphite, and galena is due to an electrostatic attraction between them and globules of an emulsion formed by the organic substance. It is claimed that these solid surfaces are positively charged and that the emulsion is negatively charged. He then proposes that such an action is the basis of flotation.

This explanation of the basis of flotation is unsatisfactory. Adsorption of xanthates occurs readily from true solutions of their alkali salts, and flotation is possible in the absence of any emulsification. Moreover, the author himself states that there is a decrease in the potential of the surface, even when the emulsion is so dilute that its character is lost. It is uncertain what is meant by this change, but if it means a transition to true solution, the experimental results become very interesting in another connexion. They would then hint that adsorption from solution is accompanied by a decrease in the potential of the surface, from which it might be argued that negative ions—presumably xanthate ions—are adsorbed. This conclusion has been reached on other grounds.

### The Cry of Tin

THE experience of Dr Chalmers<sup>1</sup> with regard to the 'cry' emitted by cadmium and tin during plastic deformation agrees exactly with that of Mathewson and Phillips<sup>2</sup> obtained in coarsely crystalline zinc. In 1927 they recognised and discussed a silent process of simple slip which was unproductive of twins, and,

furthermore, a type of deformation which caused both a 'crackle' and multiple twinning.

In his letter, Dr Chalmers states that he has not been able to produce a cry with any metal crystallising in a cubic system, for which twinning does not take place. Lest there be any ambiguity, it may be said that cubic metals sometimes show mechanical twinning, the Neumann bands of  $\alpha$ -iron being a case in point. During experiments involving the cold-rolling of crystals of iron containing 1.8 per cent of silicon, I distinctly heard a crackling sound from the metal, and subsequent examination showed the presence of twins.<sup>3</sup> That this is no unique observation is evident from the work of Mathewson and Edmunds<sup>4</sup> on silicon-bearing iron, but they take the matter somewhat further. In their 1928 paper we read "Single crystal strips with cubic planes nearly parallel to the surface, cracked noticeably when pinched between rolls but produced only a few bands. When rolled on dodecahedral planes, virtually all the deformation occurred by a quiet slipping process." It may be pointed out here that compression or rolling of iron crystals on (011) faces produces much more strain-hardening than compression on cubic faces.

Dr Chalmers observes that the 'cry' was only noticed in aggregates which exceeded a certain crystal grain size. I have observed that in  $\alpha$ -iron the larger the grain size the greater is the ease of production of Neumann bands, and the smaller the resistance of the metal to failure by shock.<sup>5</sup> Ordinary fine-grained iron only twins at room temperatures by impacting, but the addition of certain other elements both enlarges the grain size and permits of the production of twins by static deformation. The elements which behave in this way are phosphorus, tin, silicon, and aluminium, and it is perhaps not without significance that metallurgically they may roughly be described as deoxidisers.

### Isotopic Constitution of Lead

As described in a previous communication,<sup>1</sup> we have found from the hyperfine structure of the lead spectrum that the ordinary element contains, in addition to  $\text{Pb}^{208}$ ,  $\text{Pb}^{206}$ , and  $\text{Pb}^{207}$ , a fourth isotope,  $\text{Pb}^{204}$ , with an intensity of 1 per cent. Owing to the presence of mercury (particularly  $\text{Hg}^{204}$ ) in the discharge, the first analysis of lead by means of the mass spectrograph could not detect this new isotope. Recently, Aston<sup>2</sup> has repeated his analysis and reported  $\text{Pb}^{204}$ , together with four other weaker isotopes (209, 203, 205, and 210).

As our communication was not mentioned by Aston, we wish to point out that his data concerning  $\text{Pb}^{204}$  are in good agreement with ours. Although, according to Aston's results, 209 is just sufficiently intense to be observable by our method, our plates show no indications of its presence. With regard to 203 and 205, which are also the mass-numbers of the thallium isotopes,<sup>3</sup> it should be mentioned that thallium was always present in spectroscopically appreciable quantities in all our samples of ordinary ('accumulator') lead. We therefore consider that the possibility of a contamination of the sample by traces of thallium should not be overlooked before the mass numbers 203 and 205 are finally attributed to lead. This point illustrates an advantage of the spectroscopic method, as the wave-lengths of the spectral lines are determined

chiefly by the external electron configuration of the atom—the isotopic effect enters only as a part of a hyperfine structure of the individual multiplet lines

On account of the increased attention now being given to the study of very rare isotopes (abundances less than 1 in 1000) we would like to suggest that, in investigations where the isotopes of neighbouring elements (present as impurities) might cause difficulty, the preparations should be submitted to a spectroscopic analysis before the results are considered as final. As is well known, the sensitivity of the spectroscopic method surpasses that of any chemical test

### Activated Adsorption of Hydrogen

THE great revival of interest in adsorption measurements, carried out in connexion with catalytic experiments, which is manifested by the Oxford meeting of the Faraday Society, and by other similar publications, has prompted us to announce some results which we have obtained

The adsorptions of hydrogen, hexane, cyclo-hexane, and benzene, at temperatures up to 450°, have been measured on a large number of metallic oxides. Attention has been primarily concentrated on substances which have known catalytic activities in hydrogenation, and on those which have not already been inspected by Prof Taylor in Princeton. We have discovered that extensive 'activated' adsorption of hydrogen occurs with oxides of molybdenum, vanadium, chromium, and tungsten, and with metallic tin and cadmium

Adsorption of hydrocarbons at high temperatures (up to 450°) is now found to be a still more general phenomenon, and takes place with every metal or metallic oxide which we have inspected so far (Cr, Ti, Fe, Cu, Mo, Zn, Cd, Ca, Zr, Mg, Sn, Co, Al, Mn, and W). The velocity and extent of the adsorption vary greatly in different cases, and are also considerably influenced by the presence of impurities, complications due to interaction of hydrogen with the solid have been avoided by pretreatment of the latter

It is hoped to give an account, *in extenso*, of these experiments in the near future, as they should provide an interesting contribution to the study of catalysis

### Interaction of Flavones and Anthocyanins

ROBINSON and Robinson<sup>1</sup> have recently directed attention to the existence of 'co-pigments' which, entering into loose combination with anthocyanin pigments, modify their colour

In the course of my genetic experiments on *Dahlia variabilis*, it was found that the ivory flavone in the flowers apparently had the property of changing the anthocyanin colour in the direction of blue, for example, cyanin alone gives almost a chocolate colour but with ivory flavone the colour is bluish-purple. Apparently ivory flavone acts as a co-pigment for cyanin and pelargonin in *Dahlia*

Recently I have tested, *inter alia*, the crude pigment extracts from flowers of widely different plants (for example, *Dahlia*, *Primula* spp., *Pelargonium*, *Tulipa*, and *Pulmonaria*). In a number of cases the ivory flavone pigments, independent of hydrogen ion concentration, have been found to bring about modification of anthocyanin colour. The blueness disappears on heating the solution, but returns on cooling. The ivory flavone effect may be additional to that of co-pigments, other than flavone, already present. Reciprocal differences were found in certain cases

Further, in *Dahlia* there is an inverse correlation between the production of flavones and anthocyanins, the interaction being reciprocal, but to the advantage of the flavones, thus if much flavone is produced, then little anthocyanin is formed. The same phenomenon occurs in other plants. Anthocyanin intensity, therefore, may depend to a considerable extent on the presence or absence of flavones

Changes in the hydrogen ion concentration of the sap have long been known as one cause of flower colour variation. Differences in the specificity of the anthocyanins constitute another. In view of the universal distribution of flavones, it seems probable that they will be found to comprise an important and hitherto unrecognised source of variation in both flower colour and intensity. A full account of these experiments will be published elsewhere

### Science and Disarmament

AN article in *NATURE* of April 4, 1931, pointed out the connexion between science and the preparator for war, in reference to Major Lefebure's book "Scientific Disarmament". I understand from friends of mine, who are scientific workers, that in all countries some men of science regard as important the problem of their own moral responsibility for the use of scientific knowledge in preparation for war. Deliberate application of science in the development of armaments is transforming the nature of weapons and the general character of war. As Major Lefebure has shown, the gravest problem is the development of new types of weapon, and yet neither the official policies of governments nor the proposals of unofficial bodies seem to envisage this problem

Would it not be possible to form a small group of chemists, physicists, and other scientific workers of standing, in Great Britain—and also in France, Germany, and the United States—in order to make some public statement against the application of research to the improvement of gunnery, bombing, and chemical warfare? Such a statement would have influence in directing the minds of students of science towards their moral responsibility for the use of new knowledge, and the Disarmament Conference, now in session at Geneva, would be assisted if scientific workers, who provide the means for increasing the destructiveness of war, were to indicate publicly the gravity of the danger. It is obviously quite useless to abolish old armaments, if new and more deadly types of weapon are to be produced by the application of scientific research to such an end

## Research Items

**Mummers' Plays**—Mr H Coote Lake has published a study of English mummers' plays with reference to the *Sacer Ludus*, in *Folklore*, 42, No 2. The mummers' plays are performed by villagers and others over the whole of England, the south of Scotland, and the north of Ireland, but there is no standard version and all sorts of perversions have crept in. A large number of versions—one collection contains thirty-three—have been printed, and probably many more have not been collected. Although they differ verbally and incidentally, the essential structure is the same, conforming, it is suggested, to the formula of an old European ritual dance or *Sacer Ludus*, a primitive magic rite in which the death and resurrection of summer was acted, in order that, as the actor who took the part of summer was slain and revived, so the summer, which had been slain by winter, might be revived. The comic doctor, who revives the hero, is a characteristic feature of the English play, and also appears in a folk play of Thessaly. He is a survival of the primitive medicine man. The Turkish knight, who in the English play fights with St George, is represented in the Thessalian version by a character with a black face who molests the bride and slays the bridegroom. He is often thought to be derived from a dark character representing winter. A Thracian play represents a blend of a mummers' play and the Plough Monday celebration. In a considerable proportion of the plays there is a 'recognition' of the dead man, which dramatically is unnecessary. If, however, the mummers' play is to be identified with the mimetic rite, this recognition becomes the very germ of the drama.

**Marriage Conditions in Palestine**—Dr Hilma Granqvist has made a close and detailed study of marriage in the Mohammedan village of Artās over a period of three years between 1925 and 1931, of which the results have been published by the Societas Scientiarum Fennica, Helsingfors (*Commentationes Humanarum Litterarum*, 3, 3). Dr Granqvist's method has been to work by concrete examples, and she quotes her informants' words in verbatim translation, so that her information and deductions may be checked against one another. The subject is studied under three heads: age of marriage, choice of a bride, and marriage by consideration. The births of a boy and of a girl are greeted with a blessing on the 'bridegroom' or 'bride' as the case may be, and it is a usual practice for the girl thereupon immediately to be bespoken by the father of a boy. Provided the boy, or his parents on his behalf, make the customary gifts at the great feasts in after years, this promise, which has been guaranteed by witnesses and ratified by the gift of a handkerchief or the like and a present of money to the bride's father, is never broken, unless in exceptional circumstances. The marriage takes place at an early age—formerly even before puberty, until government action intervened. One of the reasons for early marriage which carried great weight was the fact that the Arabs have no female servants and it was desirable that the mother of the household should have additional female help. It also afforded the mother-in-law an opportunity to mould her son's wife to the ways of herself and the family. The marriage of the children of two brothers was the type of alliance most favoured, the interests of the family or clan being best served by such a marriage. The fathers arranged the marriages, and individual choice or love played no part.

**A Red Indian 'Buffalo Drive'**—In the ages before the domestication of cattle and the cultivation of

crops, an outstanding problem for the ill-armed hunter must have been the provision of the community's food supply. Special interest, therefore, is attached to devices for supplementing the food-supply, particularly where they involve co-operative action or careful planning. Both are commemorated in an ancient Indian 'buffalo drive' on Ox-Bow Ranch on Strickland Creek, not far from the boundary of Yellowstone Park. It was used perhaps only two or three hundred years ago, but the fifteen hundred stone arrow-heads found at the spot indicate a people whose culture was still that of a stone age. The drive was formed by two lines of stone piles approximately a quarter of a mile apart at the open end and converging over a mile of prairie until they ended some fifty feet distant from each other. The bison were herded into the open end and constrained to follow the smooth track between what seemed to them natural barriers, and these instead of terminating in a circular pound as was usually the case, ran sheer to the edge of a precipice in the lava rock, over which the stampeded herd rushed to its doom. The distribution of stone arrow-heads beneath the cliff showed how the Indians finished off the maimed animals. A steatite bowl and the arrows from the excavations made on the spot by Barnum Brown and his party (*Natural History*, vol 32, 1932, p 75) indicate that the hunters were the Shoshone Indians and not the Blackfoot tribe which inhabited that territory at the advent of white men.

**Salmon of the West Coast of Scotland**—The extensive investigations made by the Fishery Board for Scotland into the life-history of the salmon have been devoted mainly to the rivers of the east coast. Observations made in the Grimeista district in the Isle of Lewis indicated that a significant difference might be found in the biology of the salmon on the west coast. Accordingly, a number of examinations have been made by Mr P R C Macfarlane of salmon from the River Dee in Kirkcudbrightshire in the years 1928 and 1929 (*Fisheries, Scotland, Salmon Fish*, 1931, No 2). The results indicate that there is slightly more growth shown by the west coast fish in their first year in the sea than by the east coast fish. This is taken as a possible indication that salmon from the two coasts of Scotland frequent different feeding grounds in the sea, and do not migrate to a common ground in the ocean. The parr from the river under survey also showed a considerably greater growth than do those of the Spey and Aberdeen-shire Dee.

**Chromosomes of *Sorghum***—In a study of the somatic chromosomes of the genus *Sorghum*, Prof C L Huskins and Mr Stanley G Smith (*J Genetics*, vol 25, No. 2) find that the wild species and cultivated varieties examined all have twenty chromosomes, except the Johnson grass, *S. halepense*, which has forty. All, without exception, have a single pair of A chromosomes of peculiar character. The cultivated sorghums came from tropical Africa, while *S. halepense* is Mediterranean. Since it has but one pair of A chromosomes, it is probably an allotetraploid, having arisen from a cross between a diploid *Sorghum* and some other genus without an A chromosome. The evidence indicates that all the diploid wild and cultivated species of *Sorghum* will cross readily, while there is great difficulty in crossing Johnson grass with the diploid forms, and the progeny from such crosses are almost sterile. In the root tips examined, a number of tetraploid segments and one

octoploid segment were found in diploid roots. The general results are in accordance with and confirm the views already held by systematists regarding the relationships of these forms.

**Loch Doon 'Granite' of Galloway**—The igneous complex of Loch Doon has been described by C. I. Gardner and S. H. Reynolds (*Quart. J. Geol. Soc.*, 1932, pp. 1-34). The authors find that the plutonic rocks range from true granites in the central ridge to norite at certain parts of the margin, the major portion of the mass being tonalite. These three types seem to be the result of three successive intrusions in order of decreasing basicity. Numerous minor intrusions penetrate the complex and the sedimentary rocks surrounding it. They include relatively large bodies of hybrid or dioritic character and small dykes of porphyrites and mica-, hornblende-, and augite-bearing lamprophyres. Some of the dykes, however, are metamorphosed and thus appear to be pre-plutonic. Metamorphism of the sediments has resulted in the production of mica-cordierite-hornfels. The spreading out of the metamorphic aureole to include the Burnhead mass indicates an underground extension of the plutonic rocks at no great depth, and suggests that the mode of emplacement of the complex may be laccolithic.

**The Humboldt Current**—The generally accepted explanation of the Humboldt Current of the Pacific coast of South America, as being derived mainly from the westerly drift of the Southern Ocean and only partly by upwelling of cold water, is questioned by the researches of the R. R. S. *William Scoresby*. In a note in the *Marine Observer* for June, it is recorded that this ship was engaged in surveying the Humboldt Current during the winter of 1931. The current was not found, at that season, south of Valparaíso, which seems to dispute the view that the surface drift of the Southern Ocean feeds it, and favours the secondary cause, namely, the upwelling of cold water due to prevailing south-east and southerly winds. The current reaches its maximum width and greatest strength, about twenty-five miles a day, off Peru. It finally disappears about five degrees south of the equator, underneath the warmer waters of the El Niño current that sets south. The El Niño waters occasionally pass inside the cold Humboldt waters, with disastrous consequences to the climate of Peru. It must be remembered, however, that the Humboldt Current has always been known to be very variable from year to year, and its seasonal fluctuations take it well south of Valparaíso in summer and even in winter, but at that season at a considerable distance from the coast.

**Air Movement and Weather**—Sir Napier Shaw has contributed a paper entitled "St. Martin's Summer in England in 1931" to *Beiträge zur Physik der freien Atmosphäre* (Band 19). It was written in commemoration of the birthday of V. Bjerknes, whose name is familiar to meteorologists mainly on account of his important contributions to dynamical meteorology. The extraordinary spells of unseasonable warmth that occurred during the last two months of 1931 were due largely to the occurrence of long spells of southerly or south-westerly wind of subtropical if not of tropical origin; this paper discusses a part of this period centring around Nov. 3. It is shown that the gales experienced in the south-east of England on that day travelled from west of Portugal in 24 hours, that the motion of the air stream underwent acceleration, and that the adjustment of horizontal pressure gradient to velocity at once took place. This air-stream reached Scandinavia and Finland a day later.

There was nothing very abnormal in the circumstances attending these events, the value of the paper lying chiefly in the discussion of the dynamics of moving air that centres around them. Sir Napier's views on these matters, particularly in regard to the greater importance to be attached to the air movement than to the distribution of areas of high and low pressure to which the movement gives rise, have nowhere been more clearly expressed. It is shown that under the conditions existing in an atmosphere that is almost unconfined, the energy represented by the pressure distribution is of secondary importance in atmospheric circulations.

**Demonstration of Wave Groups**—A description of an apparatus for explaining the nature of wave groups has been sent us by Dr. D. B. Macleod of Canterbury College, Christchurch, New Zealand. A circular aluminium disc of about 20 cm. diameter was hollowed out and a sine wave cut on the inner portion so that a given number of waves fitted into the circle. A second disc was left solid, and a wave cut on the outer edge. The discs were then mounted, one in front of the other, and rotated at a speed great enough to eliminate flicker. Arrangements were made so that the speed of each could be varied separately. The discs were illuminated by a beam of parallel light from a lantern, and thus silhouetted on a screen. A wave group then appeared on the screen, and its velocity, forward or backward, could be controlled by adjusting the speeds of rotation. The number of waves on a disc may be so few as one, the curve then being a cardioid, or so many as eight or nine. The apparatus can be used to make clear many properties of wave groups, and, by suitably choosing the number of wave-lengths on each disc, can be made to give general ideas of the application of these properties to the electron and to quantum orbits.

**Superconductivity for Alternating Currents**—The work of Prof. J. C. McLennan and his associates on superconductivity at high frequencies (*NATURE*, Dec. 12, 1931, p. 1004) has now been described more fully (*Roy. Soc. Proc.*, May). Measurements were made on lead, tin, and tantalum by the reactions of oscillatory circuits made of these, and immersed in the refrigerant, on a tuned oscillator outside the Dewar flask. The effect of using the high-frequency current instead of direct current is twofold: the abruptness of the transition from ordinary conduction to superconduction as the temperature is progressively lowered is markedly diminished, and the temperatures of both onset and effective completion of superconduction fall. With increase in frequency, the transition temperature becomes lower, and it is calculated by extrapolation of the experimental results for tin that the transition would not occur until the absolute zero was reached for a frequency of about  $10^9$  cycles per second. The apparent failure of metals to become superconductors at sufficiently high frequencies is supported by the fact that no evidence of an abrupt change corresponding to superconductivity has ever been observed with light waves. A number of additional experiments which had to be performed to verify that the frequency effect was not due to some subsidiary cause are also described.

**The Red Nitrogen Band Spectrum**—The partial analysis of the rotational structure of these bands by S. M. Naudé (*Proc. Roy. Soc.*, May) is interesting both for the information which it furnishes about the nitrogen molecule and for the time during which these bands, which are amongst the best-known of spectra, have defied complete analysis. Even now, only a section of the system, in which there is com-

paratively little overlapping, has been analysed, an idea of its complexity being given by the fact that a resolving power of 180,000 was not sufficient to show all the existing fine structure. Each band consists of three groups of nine branches, the electronic transition being of the  $^3\Pi-^3\Sigma$  type, and the usual information has been derived from the data for the size and other properties of the molecule. Consecutive lines of the branches have alternating intensities in the ratio of approximately two to one, thus showing that the nitrogen nucleus is spinning with unit angular momentum, a conclusion which has also been reached from the study of some bands of the ionised nitrogen molecule. In making this analysis, much assistance was obtained from the quantum theory of molecular structure, which, as with atomic spectra, permits of prediction of the types of terms and, for molecules, the details of rotational structure likely to be encountered.

**Artificial Production of a Penetrating Nuclear Radiation.**—Mr. Webster's observations on the secondary radiation produced in beryllium and other light elements by bombardment with polonium  $\alpha$ -particles (*Roy. Soc. Proc.*, May; see also *NATURE*, March 12, p. 402) are an excellent example of the type of work which is usually required now to obtain new knowledge of atomic nuclei, and has only become possible through recent advances in technique with special precautions to eliminate spurious effects. The low efficiency of production of the secondary radiation, which ranges from 0.5 quanta per million  $\alpha$ -particles for magnesium to 30 quanta for beryllium, is here aggravated by the small ionising power of the product; the intensity of the effect ultimately measured when this is cut down by screens to measure its penetrating power is very small indeed. A strong  $\alpha$ -particle source is necessary, and the measurements must be made in a place free from serious radioactive

contamination. Two detecting instruments, both highly sensitive, have been used, a Geiger-Müller tube counter and a high pressure ionisation chamber, the latter being usually preferred. The counter does not appear to be fulfilling the high expectations it aroused when it was first devised—at least in the form usually employed—and is usually described as somewhat erratic in action. The full interpretation of Mr. Webster's results must remain uncertain, until it can be decided how much of what he has observed is due to neutrons and how much to  $\gamma$ -rays, but his extensive experiments will certainly serve as a sound basis for future work.

**Biological Test for Rhamnose.**—Aldo Castellani and F. E. Taylor in 1917 described a 'mycological' method for the identification of various sugars and other carbon compounds, based upon the fermentations exerted on these substances by diverse species of *Monilia*. Castellani now describes a bacillus which ferments rhamnose with gas production, but does not produce gas from twenty-eight other substances tested; these included eight other sugars, six alcohols, two glucosides, inositol, dextrin, inulin, and several starches (*Ann. de l'Institut Pasteur*, T. 47, p. 297; 1931). This bacillus, obtained from human faeces, is a small aerobic, non-spore, non-motile, Gram-negative organism which is named *B. rhamnosifermentans*. If this organism ferments a solution which reduces Fehling's solution, in all probability it contains rhamnose. The method employed is to prepare a sterile one per cent solution of the substance to be tested in peptone water in a Durham's fermentation or other tube, inoculate with the *B. rhamnosifermentans*, and incubate at 37° C. for four days; gas production indicates the presence of rhamnose. Suggestions are given whereby a mixture of sugars, etc., might be identified by the use of this and other fermenting organisms.

### Astronomical Topics

**Detection of Kopff's Comet.**—Another of the numerous periodic comets due this year has been detected. Mr. Bobone found Kopff's comet at Cordoba (Argentina) in the following position:

|                  | R.A. (1932-0).                                    | S. Decl.    | Mag. |
|------------------|---------------------------------------------------|-------------|------|
| May 25-0788 U.T. | 15 <sup>h</sup> 11 <sup>m</sup> 18.8 <sup>s</sup> | 26° 11' 12" | 12   |

It is rather brighter than was expected. The concluded date of perihelion is Aug. 21.40 U.T.; this is 0.24<sup>d</sup> later than Mr. Kepinsky's prediction, and 1.08<sup>d</sup> later than Mr. Cripps's in the "B.A.A. Handbook". This comet was discovered in 1906, and seen again in 1919 and 1926.

**Cometary Observations at Yerkes Observatory.**—Prof. G. van Biesbroeck gives much attention to observations of comets, chiefly by photography with the 24-inch reflector. *Harvard Card* 189 contains a series of observations of Nagata's comet made by him during February, more than eight months after perihelion. It was of magnitude 15½ and had a faint coma, 25" in diameter, with a central condensation. The positions indicate that the period of 267 years, found by Crommelin in the autumn, is somewhat too short, but the orbit is definitely elliptical, with a period of a few centuries.

A telegram distributed by the I.A.U. Bureau, Copenhagen, announces that Prof. van Biesbroeck detected Grigg-Skjellerup's comet on March 6 at 1<sup>h</sup> 30.3<sup>m</sup> U.T. Its position for 1932-0 was R.A. 5<sup>h</sup> 31<sup>m</sup> 49.3<sup>s</sup>, S. Decl. 5° 3.0'. Magnitude 16. This is the fourth observed apparition of the comet, the others being 1902, 1922 (when its periodicity was dis-

covered), 1927. As the period is very close to five years, the circumstances of each return are nearly the same.

**Distribution of Stellar Luminosities.**—The distribution of absolute magnitudes for stars brighter than magnitude 6.0 has been investigated by Strömberg in a series of papers in the *Astrophysical Journal*. These have dealt separately with groups of stars within narrow limits of spectral type, using a valuable new statistical method which employs peculiar motions, parallactic motions, and radial velocities. He now summarises his previous results (*Astrophys. J.*, 75, 115) and brings together on one diagram the luminosity curves for all the different spectral types. Several very interesting features which had been suggested in the earlier investigations now appear more definitely in the assembled results. The distinction between normal giants and dwarfs (or 'main sequence' stars) is, of course, evident; but the existence of an intermediate group ('faint giants') also appears for the types  $M_0$  to  $F_0$ . At type A all these three groups merge together and carry on the main sequence to a maximum luminosity of -2.9 for early B stars. On the side of greater luminosity, two other fairly well defined sequences occur, termed respectively 'bright giants' and 'super-giants', which are found throughout nearly the whole spectral range. The latter attain absolute magnitudes as bright as -8 for early B stars. The gap between bright giants and normal giants is very definite, and the author suggests that this may represent a region of instability connected with cepheid variation and outbursts of novæ.

### The Mond Photographic Equatorial of the Norman Lockyer Observatory

ON Saturday last, May 28, in the presence of a distinguished assembly, Sir Frank Dyson, Astronomer Royal, opened at the Norman Lockyer Observatory, Salcombe Hill, Sidmouth, a new building containing a unique photographic equatorial presented to the Observatory, together with the dome and building itself, by Dr. Robert L. Mond. The Observatory was founded nearly twenty years ago by Sir Norman Lockyer and Sir Francis McClean, and it first bore the name of the Hill Observatory. It was afterwards formed into a corporation under the Companies (Consolidation) Act of 1908, and Norman Lockyer's name was given to it as a memorial of the great work done for science by that renowned astronomer.

The site of the Observatory, at a height of 560 feet on the top of Salcombe Hill, and with an unbroken horizon in every direction, was presented to the Observatory by Sir Norman and Lady Lockyer. Hitherto, the two main instruments have been a twin telescope with object glasses of 12 and 10 inches aperture, presented by Sir Francis McClean, and a telescope of 10 inches aperture, presented by Sir Norman Lockyer. Each of the two telescopes is fitted with a prismatic camera—one 12 in. and the other 9 in.; and the Observatory now possesses a collection of 6458 spectra taken with these cameras. From the beginning, the Observatory has been built, equipped, and maintained entirely by private contributions, and one of its most generous supporters is Dr. Mond, who has now added to his gifts the new photographic equatorial illustrated in Fig. 1.

The construction of this instrument was suggested by the director of the Observatory, Dr. W. J. S. Lockyer, and the work has been carried out by Messrs. Cooke, Troughton and Simms. Dr. W. H. Stevenson made a thorough optical examination of the Zeiss lenses selected for mounting to form the photographic battery, and he afterwards again visited the Observatory to complete the very accurate adjustments required of the optical axes of the lenses in relation to the planes of the photographic plates. The following are extracts from his report on the new telescope and the kind of work it is capable of doing:

"The instrument has been designed for the photography of relatively large regions of the sky on a small or moderate scale. This particular class of instrument may be said to have been introduced by the late Prof. Barnard, and to have its prototype in the famous Bruce photographic equatorial, designed by him and used for his well-known photographs of the Milky Way. As will be seen, the Mond equatorial is in many re-

spects similar to the Bruce. Details of the optical equipment are shown in this accompanying table:

|    | Lens.            | Focal Length.<br>Cm. | Aperture.<br>Cm. | Size of Plate.<br>Inches. | Area Covered in<br>Degrees. | Scale of Plate<br>per Inch. |
|----|------------------|----------------------|------------------|---------------------------|-----------------------------|-----------------------------|
| 1. | Zeiss Triplet    | 120                  | 17.1             | 10 × 12                   | 14 × 12                     | 1.1"                        |
| 2. | Zeiss Triplet    | 70                   | 14.0             | 8½ × 6½                   | 17 × 13                     | 2.1"                        |
| 3. | Zeiss Triplet    | 50                   | 10.4             | 6½ × 4½                   | 18 × 13                     | 2.9"                        |
| 4. | Zeiss Anastigmat | 25                   | 7.0              | 5 × 4                     | 30 × 24                     | 6.4"                        |

There is also a 4-inch guiding telescope fitted with double sliding eye-end with bright and dark illumination to field.

"The equatorial mounting, which is of the German

FIG. 1.—The Mond Photographic Equatorial.

type, is of very massive construction, the lower half of the mounting weighing 1 ton 6 lb. That part of the casting which holds the polar axis overlaps the vertical portion very considerably, as in the Bruce mounting. This allows of complete and uninterrupted circumpolar motion at all declinations. The driving circle is very accurately cut, and is of generous proportions, its diameter being 27½ inches. The polar axis is mounted in ball bearings, and the whole instrument, when unclamped, will move at the lightest pressure of one finger.

"Setting in R.A. can be done very comfortably from floor level, the circle being let into the south side of the mounting and geared to the lower end of the polar axis. This circle is divided to five minutes of time, and the Declination circle to single degrees. Both circles are read by simple pointers, verniers and fine divisions being unnecessary for this type of instrument.

"The clock, which is driven by a weight falling in

a steel frame outside the Observatory, will run for about  $2\frac{1}{2}$  hours without re-winding. It is controlled electrically by a seconds pendulum mounted in the vestibule. Slow and rapid motions in R.A. are provided by means of a specially geared electric motor, working on the driving-worm independently of the clock.

"In recent years several American and continental observatories have added small-scale photographic instruments to their equipments, but it is believed that the Mond equatorial is the first of its kind to be erected in Great Britain.

"The uses to which the instrument can or will be put include the photography of meteors, comets, and large nebulosities of the galactic type. In addition, the search for new minor planets, comets, variable stars, and novæ can be undertaken with such an apparatus with a greater hope of success than where an instrument of greater power but smaller field of view is used. Even unsystematic work with this battery of cameras may be of considerable ultimate value."

At the opening ceremony, Sir Richard Gregory, chairman of the Council of the Observatory, said he hoped that the wide and intelligent public interest now shown in astronomical subjects would lead to increased support for the Observatory, in which valuable work in astronomy is being carried on with instruments and funds provided by private donors, and without the aid or control of State or other official institutions. Private benefactions have provided the United States with the finest observatories in the world, with the result that we owe to American astronomers some of the most important observations made in recent years in solar and stellar astronomy, particularly in the field of astronomical physics. It is perhaps too much to expect similar munificent support for astronomical research in Great Britain, but it ought not to be too much to hope that an observatory like that on Salcombe Hill, in which many notable contributions to

progressive knowledge have been made, should be placed in such a financial position that the maintenance of its activities will be ensured.

In the course of his remarks, Sir Frank Dyson said: "It is now ten years since I had the honour of unveiling here the tablet to Sir Norman Lockyer. There can be no doubt that his spirit pervades the Observatory. Constant observation seems to be the rule, and there are more fine nights here than we have at Greenwich. Dr. Lockyer produces for us with regularity valuable papers on stars with bright hydrogen lines. He is making constant observations of stars in which the intensity of the components of these lines varies. A star in Camelopardalis, Bradley 448, he observed through the entire cycle 1925-30 of its variability. He has also discussed  $\phi$  Persei and a number of other stars, and has discovered a number of new stars with bright hydrogen lines. Mr. Edwards is repeatedly bringing out spectroscopic parallaxes of early type stars. The influence of the Observatory is felt as far away as Canberra, where Mr. Rummer is carrying on valiantly under difficult financial conditions. I am quite sure Sir Norman would have been delighted to see how the work, in which he was so greatly interested, is being developed."

Dr. R. G. Atkin, director of the Lick Observatory, said that he always read with great interest the papers describing the spectroscopic and other observations and results achieved at the Observatory, and he congratulated the Council upon the addition of a most useful instrument to its equipment. Dr. Mond, in his reply, referred to his long association with Sir Norman Lockyer and Dr. Lockyer, and said that he regarded the new instrument as an astronomical 'robot' which would faithfully record celestial appearances and events over wide fields of view while the staff of the Observatory was carrying on the routine spectroscopic work on individual stars, and the photographs thus obtained would be of permanent value for astronomical reference and discovery.

### International Committee of the History of Science

THE fourth annual conference of the Comité International d'Histoire des Sciences was held in Paris on May 13-16, under the presidency of Prof. Karl Sudhoff. Among those present were Mme. Hélène Metzger, Prof. P. Diepgen, Prof. F. Faddegon, Dr. E. J. Holmyard, Prof. Louis Massignon, Prof. Aldo Miel (permanent secretary), Prof. E. Mittwoch, Prof. A. Raymond, and Prof. D'Arcy W. Thompson. The meetings were held at the Centre international de Synthèse (12 Rue Colbert), and, apart from formal business, were devoted entirely to the history of the sciences in medieval Islam. The president, Prof. Sudhoff, read a paper on Constantine, the first to transmit Muslim science to the West, and described the part played in this transmission by Maurus and Urso, two early schoolmen of Salerno. Prof. Massignon, in a brilliant discourse, pointed out the contrast between Greek and Muslim conceptions of numbers, and suggested the importance of Manichaean ideas in early arithmetic.

The present state of research into Arabic mathematics, astronomy, and physics was fully described in a report by Prof. Faddegon, and similar reports on geography, cartography, and medicine were presented by Profs. Ferrand, Renaud, and Mittwoch. The chairman of the sub-committee for Arabic studies, Prof. Julius Ruska, was unfortunately not able to attend the conference, but his report on Arabic alchemy was read by Prof. Diepgen. Though much has been done in recent years, particularly on the Jabir problem, the Emerald Table of Hermes, and the Turba

Philosophorum, it was evident from Prof. Ruska's report that the full elucidation of Muslim alchemical ideas and practice will require many years of intensive effort. In the course of the discussion, it was suggested that an urgent need is the detailed investigation of the numerous works of Andamun al-Jildaki, while a catalogue of Arabic alchemical manuscripts in Spain is greatly to be desired. The possibility was mooted of establishing a central card index of Arabic technical and scientific terms, to supplement the meagre information on this subject contained in the standard dictionaries of Lane, Dozy, etc. A collateral index of alchemical and other signs was also considered desirable.

A further problem that the Comité regards as worthy of close attention is the assessment of the influence upon Muslim scientific thought of the doctrines of Gnosticism, Neoplatonism, and Manichæism, the latter in particular, according to Prof. Massignon, has left very distinct traces in Muslim alchemical theory. The question of the systems of transcription of Arabic words gave rise to considerable difference of opinion, but it was generally felt that no single system is likely to attain universal adoption, however desirable such uniformity may be.

On Saturday, May 14, members of the conference were given a delightful reception at the Sorbonne, by the Institut d'études islamiques and the Institut d'histoire des sciences. The next annual meetings of the Comité will be held at Warsaw (1933) and Berlin (1934).

## The Provincial Universities of Great Britain

IN the October (1931) issue of the *Universities Review*, Prof E R Dodds opened a discussion on the question, "What is Wrong with the Modern Universities?" Further articles in the April issue carry the matter on another stage. These outspoken essays are in general agreement as to there being ample grounds for the implied assumption of failure to realise an ideal, and incidentally testify to the value of Dr Abraham Flexner's recent work, "Universities American, English, German", in stimulating thought on the subject.

Most students of the modern universities are, according to Prof W M Tattersall, whose presidential address to the Association of University Teachers is reproduced in the April issue of the *Review*, uncivilised and, in a broad sense, uneducated. They are conspicuously lacking in that *bildung* which Flexner holds to be characteristic of the product of the ancient universities. Prof Tattersall attributes this largely to the fact that only a small percentage of the students are able to live in colleges or hostels, the larger number living either at home or in lodgings. Pending or failing the provision of a complete and compulsory residential system, an organised effort should be made to promote informal and social contacts between staff and students. He suggests, and the scheme is not without precedents, that the students should for this purpose be allotted in groups to members of the staff, each of whom would act in the capacity of 'moral' tutor to the group assigned to him (or her).

In an article headed "University Uniformity", in the same issue, Prof R C McLean observes that the root of the trouble with our local universities is that they are so intensely local. He is in favour of spells of wage-earning during the study years and migration between universities. Two other articles discuss the same problem with special reference to the large proportion of the students of the modern universities who are destined for the teaching profession.

The teacher-training departments occupy in the modern provincial universities a position peculiarly favourable for estimating the effects of the educational processes at work in the arts and pure science departments. The diploma course of these departments includes graduates from many different schools of the university, and while pursuing it they show 'the mettle of their pasture'. It is fitting, therefore, that there should be two articles by members of the staffs of teacher-training departments, namely, Profs F A Cavenagh and J F Duff. Both are of opinion that students suffer from being over-taught in the effort to cover the whole of the ground defined by an elaborately prescribed syllabus, with the result that they have little time for spontaneous learning.

Since lectures cannot be dispensed with or the lecture programme greatly reduced while the students are so numerous in proportion to the staffs, the remedy, suggests Prof Cavenagh, lies in improving the lectures. Too many university teachers give but little thought to their teaching as an art in itself, regarding skill in teaching as something that comes by itself or is beneath the notice of a competent scholar. The 'research' fetish, moreover, has largely ousted the ideal of the well-educated, well-read student with more than one intellectual interest. Both articles direct attention to the evil results that follow in many cases the choice by students of a highly specialised course merely because it seems the only avenue to the goal of a 'good honours degree', notwithstanding that a less specialised course would be more congenial and of greater practical utility.

## University and Educational Intelligence

CAMBRIDGE—The Managers of the Balfour Fund have made the following grants: (1) £100 to I T Sanderson, of Trinity College, for an investigation of the land vertebrate fauna of the Cameroons; (2) £30 to D L Serventy, of Gonville and Caius College, for a biological survey of the East Anglian estuaries.

W E Candler, scholar of Trinity College, has been elected to the Sheepshanks Exhibition.

The Council of the Senate recommends that the readership in ethnology be discontinued, and that there be established a William Wyse professorship of social anthropology, which shall be held in the first instance by Col T C Hodson, of Christ's College.

The General Board recommends that the subject of pharmacology be placed under the superintendence of the professor of physiology in the Department of Physiology, and that the University lectureship in pharmacology be transferred from the Faculty of Medicine to the Department of Physiology in the Faculty of Biology B.

The Board of Research Studies has approved Mr U R Evans, of King's College, for the degree of Sc D.

A Research Studentship at Emmanuel College, of the maximum annual value of £150, will be awarded in July. Preference will be given to candidates who have already completed one but not more than two years of research. Applications, including a statement of the proposed course of research, must reach the Master, Emmanuel College, Cambridge, not later than June 30.

OXFORD—On May 24, Congregation passed a decree acknowledging with gratitude the offer of the Rockefeller Foundation to contribute a sum not exceeding 2,300,000 dollars, together with an additional 10 per cent of the estimated cost of construction, towards the extension of the Bodleian Library, on condition that the University shall have received for the same purpose a total of £377,720 before the end of 1936. In proposing the adoption of the decree, the Warden of New College mentioned that the scheme included the addition of a new wing to the Radcliffe Science Library at the Museum.

THREE post-graduate scholarships in pure and applied science are being offered by University College, Nottingham. The value of each is £100, and they are tenable for one or two years. Forms of application, returnable by July 21, can be had from the Registrar of the College.

## Calendar of Geographical Exploration

June 5, 1594—Barents in the Arctic

A Dutch expedition, with William Barents (Willem Barentszoon) in charge of one ship, the *Mercuurius*, sailed from Texel to search for the North Sea route to the east. Barents on this voyage discovered and explored the northern part of Novaya Zemlya. Two of the other vessels that left the Texel on that date were in charge of Jan Huyghen van Linschoten, a distinguished Dutch mariner, and they penetrated into the Kara Sea. Linschoten's report resulted in the sending of a second Dutch expedition in 1595, which, however, was compelled by ice and contrary winds to return when it had barely entered the Kara Sea. A third Dutch expedition, this time organised by the city of Amsterdam, sailed on May 10, 1596, with William Barents as chief pilot. They discovered Bear Island and part of Spitsbergen, which Barents, however, thought was Greenland. On returning to Bear Island, Barents sailed south and the other ship

north Barents and his party were compelled to winter at Ice Haven, the first record of western Europeans wintering in the arctic. They suffered severely, though a lucky find of driftwood prevented them from dying of cold. In early June they started their return journey, their boats being in constant danger from floating ice. Barents, enfeebled by his winter hardships, died, but de Veer brought the vessels home in November 1597, being much helped by meeting the companion ship which had left them at Bear Island and now brought them supplies of food.

#### June 5, 1866 — Valley of the Mekong

An expedition sent out by the French Government left Saigon to explore the Mekong, Doudart de Lagrée being in command and F. Garnier accompanying him as geographer. They went up the Mekong to Pnom-Penh and examined the ruins of Angkor. Thence they reached the confluence of the Se-khong, which was examined as far as Siempang. Bassac was made a centre for expeditions to the Boloven plateau, the Se-don, and the divide between the Se-don and the Se-khong. From Bassac they continued up the Mekong to the Se-mum, and from Ubun, on that stream, Garnier made an overland traverse through Siemreap to Pnom-Penh. After other expeditions, the party reached Chieng Kong, but could proceed no farther because of rapids. They went north-east, and reached Yunnan on Dec. 21. De Lagrée died before the expedition ended, but Garnier made his way to the Yangtse-kiang and returned by sea to Saigon. This journey is memorable alike for the immense amount of new country opened up and for the wealth of geographical, ethnological, and economic data collected and afterwards published.

#### June 7, 1576 — Rediscovery of Greenland

Martin Frobisher sailed from the Thames in search of a north-west passage to China, the effort being a result of a pamphlet published by Sir Humphrey Gilbert arguing that such a passage must exist. On July 11 he sighted Friesland (Greenland), and in August reached 63° N., where he entered Frobisher Bay. He believed that this was the strait for which search had so long been made. Descriptions of the Eskimo and their customs are included in the narratives of this and subsequent voyages. Frobisher's interest in discovery was diverted to a search for gold in the region. On his second voyage in search of that metal he discovered, apparently accidentally, the channel now called Hudson Strait. Frobisher may be considered the pioneer of arctic navigation.

#### June 8, 1924 — Mt. Everest

G. L. Mallory and A. C. Irvine left Camp 6, altitude 26,800 ft., for their attempt on the summit of Mt. Everest, and N. E. Odell caught a glimpse of them before the mists enshrouded them. They never returned. Bad weather had been experienced on the march, and Norton, Somervell, and Mallory had, after heroic efforts, rescued four porters who had remained on the North Col and been cut off by a hurricane. Norton on June 4 had been attacked by snow-blindness, but Hingston and Hazard led the blind man successfully down the steep and difficult descent. A Gurkha officer and a Tibetan follower lost their lives. The attempts on Mt. Everest in 1921, 1922, and 1924 resulted in the survey of the Rongbuk glacier region, and in much new topographical information about the region. The work of Major R. W. G. Hingston threw much light on the struggles of animals to exist in high altitudes, while that of Heron and Odell contributed to the knowledge of the geology and glaciology of the region.

#### June 11, 1774 — Nootka Sound

Juan Perez sailed from Monterey in the *Santrago*, and reached lat. 55° N. On the return voyage he touched the harbour now known as Nootka Sound, in 49° 35', naming it San Lorenzo. In 48° 10' he sighted a peak which he called Santa Rosalia, the modern Mount Olympus.

ERRATUM — In NATURE of May 28, p. 805, the date of Livingstone's death is given as April 30, 1830, this should read April 30, 1873.

### Societies and Academies

#### LONDON

Royal Society, May 26 — E. V. Appleton and R. Naismith. Some measurements of upper atmospheric ionisation. Experimental work on the reflexion of wireless waves by the upper atmosphere has shown that if the frequency of waves, projected vertically upwards, is steadily increased, the Kennelly-Heaviside layer (Region E) is ultimately penetrated and reflexion takes place at the upper region (Region F). The critical penetration frequency varies diurnally and seasonally. From measurements of the critical penetration frequency made in south-east England, the maximum ionisation content of the Kennelly-Heaviside layer is at noon, and a minimum occurs just before dawn. The diurnal variation curves correspond very closely to the theoretical curves obtained by S. Chapman in his study of the atmospheric ionisation produced by a solar stream of monochromatic radiation. Summer noon ionisation is found to be about 2.5 times as intense as winter noon ionisation. — J. D. Cockcroft and E. T. S. Walton. Experiments with high velocity positive ions (1 and 2). In order to obtain high steady potentials for the acceleration of protons, a method has been developed by which the voltage of a transformer can be rectified and multiplied several times by an arrangement of valves and condensers. A rectifier system has been built consisting of four glass cylinders placed end to end and arranged in the form of a tower 12 ft. high, the cylinders containing suitable electrodes and hot filaments and being evacuated continuously. With this apparatus and four condensers, a potential of more than 700 kv. has been obtained, which is steady to within a few per cent. The method used is a special case of a more general method of transforming steady potentials from low to high voltages and in the reverse direction. The voltage of the rectifier is applied to an experimental tube which is built to allow positive ions to be accelerated by the full voltage available. Positive ions of hydrogen are directed down the axis of two glass cylinders and focused by suitable electrodes, current of the order of 10 microamperes being obtained. Protons having energies up to 710 kv. have been produced, and have been transmitted through a mica window into an experimental chamber at atmospheric pressure, where their ranges are measured (see also NATURE, April 30, p. 649).

#### PARIS

Academy of Sciences, April 18 — H. Douvillé. The formation of flints. The properties of colloidal silica suffice to explain the formation of flints, without the necessity of assuming a true solution of the silica. The same explanation may apply to pyrites. — C. Matignon, Dode, and Mlle. Langlade. Urea phosphate. Details of preparation, solubility, and hydrolysis of phosphate of urea,  $\text{CO}(\text{NH}_2)_2 \cdot \text{H}_3\text{PO}_4$ . — Louis Roy. The internal thermodynamic potential of an elastic

line with six parameters—Joseph Boucher A new, or slightly known, property of the radicles of germinated barley A suggested treatment for diabetes—Eugene Donard and Henri Labbe The existence in the malt dust of germinated barley of a substance possessing hypoglycæmic power and acting in a manner analogous with insulin The action was proved by experiments on rabbits—Long The geometric definition of a group of  $\Sigma$  surfaces—André Weil The series of polynomials of two complex variables—F Marty The second and third derivatives of a holomorph and univalent function in the circle unity—Alfred Rosenblatt The stability of the movements of Couette—Henri Porcin The stationary cavitations in a fluid in irrotational movement—J Peres and L Malavard Electrical analogies in hydrodynamics—Kivelisvitch The null velocities in the problem of three bodies—G Rougier A photoelectric photometer with amplification for the measurement of feeble illuminations The instrument is standardised by comparison with a stable light standard after each measurement, and has been applied to numerous observations on the moon—Émile Belot The origin and evolution of stars and amorphous nebulae, according to the dualist cosmogony—André Berthelot The unit of length employed in the first measurements of the earth's circumference From an examination of the data available, it is concluded that Posidonios and Ptolemy used the same unit of length as Eratosthenes, namely, the Egyptian stadium of 157.5 metres—Y Rocard Regulated valve oscillators—R Chevallier The magnetisation of ferromagnetic powders in weak fields—Th V Ionescu and C Mihul Free electrons of ionised gases in the magnetic field—Leon Dubar The constitution of the oxide of rectifiers and of photoelectric cells using cuprous oxide The rectifying layer has been submitted to examination by chemical, microscopical, X-ray, and electrical methods Cuprous oxide is a non-conductor, and the cause of the conductivity is disseminated throughout the mass in very small quantity This hypothetical cause of the conductivity, possibly  $\text{CuO}$ , can only be present as a solid solution or colloid solution—G Siadbei A new method of measuring very small angles of rotation The method is based on the reflexion from the curved surface of the air bubble in a spirit level An amplification of 400 is obtained—A Silveira The Raman effect in solutions of salts—J J Agarbiceanu The anti-Stokes term in the fluorescence spectrum—H Jedrzejowski An example of the mobility of radioactive atoms on the surfaces of solid bodies A study of the diffusion of polonium over the surface of platinum at various temperatures—Francis Perrin The existence of neutrons and the constitution of nuclei of light atoms—Pierre Auger The radioactivity of potassium—H Hering The heterogeneous equilibria in the system cadmium bromide, potassium bromide, and water—Martineau The oxidation of ethyl alcohol by air in presence of various binary or tertiary catalysts The catalysts used included charcoal-zirconia, charcoal-thoria, copper-cerium oxide, copper-thoria, and catalysts containing three constituents One catalyst containing carbon, thoria, and copper caused the production of aldehyde at the ordinary temperature—Raymond Buret Chlorine and phosphorus compounds derived from dibenzoylmethane—Mlle Madeleine Roy Cryoscopic researches on castor oil—Jacques Bourcart and Mlle Elisabeth David The series of Foraminiferous grits of Ouezzan (Western Morocco)—Y Milon The extension of Eocene siderolithic formations in the centre of Brittany—Thorai Tectonic outline of the eastern part of the Monts de Lacaune—P Fallot The connexions of the

series with Alpine facies identified between Sierra Sagra and Alicante—Albert Michel-Lévy The existence of pre-Cambrian formations in the Montagne Noire (Hérault)—R Bureau The daily variation of atmospheres at Paris, 1928-31 The respective influences of the sources and of the propagation—P L Mercanton The inversion of the magnetic inclination during geological epochs New proofs—Ad Davy de Virville The flora of the reefs of the roadstead of Saint-Malo—O Munerati The possibility of the beetroot producing seed the first year in Egypt and in other regions with a similar climate It is proved by experiment that a type with a marked tendency to seed the first year shows clearly the same tendency in regions where the production of seed the first year has never been proved before—A Maige The rôle of the plast and cytoplasm in the amylogen condensation—Paul Becquerel The latent life of the spores of mosses at low temperatures After 240 hours' exposure to the temperature of liquid nitrogen ( $-190^\circ \text{C}$ ) the moss spores all germinated with the same regularity as controls In further experiments on the dried spores of *Atrichum undulatum* and of *Dicranella heteromalla*, exposure for 9 hours in liquid helium at  $-269^\circ \text{C}$  and one hour at  $-271.16^\circ$  was found to leave the germinating power unaffected—Mlle A Dusseau A hybrid haplodurum resulting from crossing two *Triticum vulgare*—Jules Amar The coefficient of hydrothermal partition—Augustin Boutaric and Maurice Doladihe The principle of a physical method by means of which the transformations produced by dilutions in a serum may be followed—Neda Marinesco The effect of intense diathermy on plants—Maurice Nicloux The combustion of alcohol in the homeotherm The quantity of alcohol burnt in unit time, for unit weight of body is constant In white mice this constant is 0.65 mgrm per gram-hour—Henri Marcellet Oil of *Orthagariscus mola*, modifications due to parasites Abnormal proportion of cholesterol—G Warcollier and Aug Le Moal The accidental presence of acrolein in cider brandy—Mme S Lallemand The distribution of chloroform in the egg of the fowl in the course of the intoxication of the germ by this anæsthetic The order of magnitude of the cellular toxic dose—M Advier The existence in the blood of a convalescent plague patient of a principle breaking down Yersin's bacillus—R Pons and C Durieux The existence in the bubo of a convalescent plague patient of an agent of transmissible lysis, apart from its presence in the intestine—Ph Lasseur, M Pierret, A Dupaix, and C Maguitot Remarks concerning the correcting note of M Lakhovsky—Andre Pling Contribution to the study of the bactericidal power of metallic silver with respect to the typhoid bacillus and coli bacillus It is shown that metallic silver is slightly soluble in water (concentration of the order  $1 \times 10^{-5}$ ), and that this affords an explanation of its bactericidal action

## CRACOW

Polish Academy of Science and Letters, Feb 15—Lad Orlicz (1) A certain class of spaces of type  $B$ —(2) The theory of the differential equation  $y' = f(x, y)$ —(3) Contributions to the theory of orthogonal developments ( $Pt\ III$ )—C Zakrzewski and M Miesowicz Feebly damped short electric waves It has been known for some time that metallic tubes transform the damped electric waves produced by spark vibrators With tubes of different cross sections, short waves, only slightly damped, can be obtained The authors have been able to produce by this method waves of a wave-length of 50 mm—M Centnerszwer and J Szper The electrolysis of alkaline cyanides An attempt to put the prepara-

tion of the alkali metals by the electrolysis of the cyanides on a commercial basis—J Zawadzki and S Bretsznajder The course of the reactions between calcium oxide and sulphur dioxide and calcium oxide and carbon dioxide—J Tokarski New microscopic and chemical analyses of the phosphites from Grodno (Poland)—J Jarocki and Z Raabe Three new genera of Infusoria of the Hypocomidæ family (*Ciliata Thaumotricha*), parasites of fresh-water lamellibranchs—J Zacwilichowski The innervation of the sense organs of the wings of insects (3)

## SYDNEY

Royal Society of New South Wales, Dec 8—M B Welch, F A Coombs, and W McGlynn Notes on wattle barks (3) An investigation has been made of the tannin content of the barks of the principal species of *Acacia* belonging to the so-called 'decurrens' group Six species which can be recognised are described and a number of bark analyses are given *A mollissima* is the outstanding species with regard to tannin content, although *A decurrens* and *A Arundelliana* yield useful barks and may prove of value under conditions which are unfavourable to *A mollissima*—E Cheel and M B Welch A new species of wattle The new wattle is closely related to the 'silver wattle' (*Acacia dealbata*), but has longer leaflets and not so many pairs of pinnae, and the whole leaf has a fern-like appearance, which has prompted the colloquial name 'fern-leaf wattle' It has some resemblance to the 'tan-bark wattle' or so-called 'black wattle' (*Acacia mollissima*), but the 'fern-leaf wattle' flowers during July-August and has broad, flat pods, whereas the 'tan-bark wattle' flowers during November-December months and produces very narrow pods—M B Welch Notes on the shrinkage of wood A list is given of the lateral and volumetric shrinkages, densities, etc., measured on a number of the more important woods in use in New South Wales

## WASHINGTON, D C

National Academy of Sciences (*Proc*, vol 18, No 2, Feb 15)—Arnold Gesell The developmental morphology of infant behaviour pattern (with a demonstration of methods of systematic cinematography) Twenty-five or more children were examined at lunar month intervals, from four to fifty-six weeks of age, written and cinematograph records being taken to describe posture, locomotion, prehension, and so on An observation dome 12 ft in diameter with a special crib at the universal focal area has been built at the Yale Clinic of Child Development, the dome is encased in a white painted wire screen, and when illuminated, the observers and cameras outside the screen are effectively concealed Illustrative series from films taken are reproduced in the paper—Alan W C Menzies and D A Lacoss Allotropy of liquid benzene The data of other workers show that the rate of change with temperature of several physical properties alters abruptly at about 40° C—Wilder D Bancroft and John W Ackerman The fading of lakes and dyed fabrics An experimental investigation of the fastness of various dyes and mordants under different conditions—A Dorothy Bergner and A F Blakeslee Cytology of the *ferox-quercifolia-stramonium* triangle in *Datura* Differences of chromosome configuration have been found which are interpreted as due to segmental interchange—G W Beadle A possible influence of the spindle fibre on crossing-over in *Drosophila* Evidence is found of interference in the immediate neighbourhood of the spindle fibre—J L Walsh An expansion of meromorphic functions—A J Lotka Contribution to the mathematical

theory of capture (1) Conditions for capture Consideration of a system comprising one prey species and one predatory species—Edward V Huntington A new set of independent postulates for the algebra of logic with special reference to Whitehead and Russell's "Principia Mathematica"—D V Widder Preliminary note on the inversion of the Laplace integral—Francis D Murnaghan On the unitary invariants of a square matrix—Tracy Yerkes Thomas Conformal tensors (2)—Luther Pfahler Eisenhart Intransitive groups of motions—Solomon Lefschetz On certain properties of separable spaces—Eberhard Hopf Complete transitivity and the ergodic principle—Francis G Benedict, Edward L Fox, and V Coropatchinsky The incubating python a temperature study Sitting and broody hens were thought to have high temperatures, this has been disproved Lamarre-Picquot claimed in 1832 that the python coils about her eggs to supply heat for their incubation It has already been shown by Benedict and his collaborators that under ordinary conditions the body temperature of a snake is slightly below that of the environment Similar studies on an incubating python show that its body temperature is about 3° C above that of the environment It is suggested that the incubating python is an intermediate stage between non-incubating reptiles and birds in the scale of evolution from cold- to warm-blooded animals

## Forthcoming Events

## FRIDAY, JUNE 3

PHYSICAL SOCIETY OF LONDON AND OPTICAL SOCIETY (at Imperial College of Science and Technology), 2 30 to 5 30, and 7 to 9 30—Joint Discussion on Vision  
ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30—Dr J H Hutton Census of India, 1931 (Lecture)  
ROYAL SOCIETY OF MEDICINE (Disease in Children Section), at 5 30—Annual General Meeting  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof J C McLennan Electrical Conductivity of Metals at the Lowest Temperatures

## SATURDAY, JUNE 4

ROYAL OBSERVATORY, GREENWICH, at 3 30—Annual Visitation  
INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section)—Summer Outing to Southampton

## MONDAY, JUNE 6

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4 30—Sir Ambrose Fleming Some Recent Scientific Discoveries and Theories (Presidential Annual Address)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 5—General Meeting

## TUESDAY, JUNE 7

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr J W McNee The Liver and Spleen their Clinical and Pathological Associations (Croonian Lectures) (2)  
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30—Prof W J Sollas The Sagittal Section of the Human Skull Pt II Palæanthropic Skulls (Lecture)  
INSTITUTE OF BRITISH FOUNDRYMEN (Annual Conference) (at Newcastle-upon-Tyne) (continued on June 8 to 10)

## WEDNESDAY, JUNE 8

GEOLOGICAL SOCIETY OF LONDON—L R Wager Geological Work in East Greenland during the British Arctic Air-Route Expedition, 1930-31 (Lecture)  
UNIVERSITY OF OXFORD (in University Museum)—Dr R A Fisher Social Selection of Human Fertility (Herbert Spencer Lecture)

## THURSDAY, JUNE 9

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5—Dr J W McNee The Liver and Spleen their Clinical and Pathological Associations (Croonian Lectures) (3)

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 730—Annual General Meeting  
CHELSEA PHYSIC GARDEN—Dame Helen Gwynne Vaughan  
The Contribution of Plants to the Study of Heredity  
(Chadwick Lecture)

## FRIDAY, JUNE 10

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section)  
(Annual General Meeting), at 5—E Clarke Tay's  
Choroiditis

ROYAL SOCIETY OF MEDICINE (Laryngology and Otology  
Sections) (at Eye and Ear Hospital, Portsmouth)—  
Summer Meeting (*continued on June 11*)

## JUNE 16 TO 18

ANNUAL COLLOID SYMPOSIUM (at Ottawa, Canada)

## The Colonial Forests and their Staffs

AS will be remembered, one of the problems considered by the first Empire Conference of Prime Ministers which met in London was the question of forestry in the Empire and the method by which a common and consistent forest policy should be formulated and adhered to afterwards by the individual parts. Empire settlement in connexion with forestry was one of the aspects to which attention was given. These matters were fully considered by a Forestry Subcommittee which was set up.

One of the dangers inherent in a problem of this type is the almost inevitable prominence given to the utilisation side of the question, obviously the best understood, and, it may be added, the best propaganda, when forests and forestry are in question. An examination of the memoranda and reports published displays the rather overwhelming preponderance given to the question of the world's timber supplies and the possibility of the Empire (a) becoming more or less self-sufficient in timber supplies, (b) developing larger export markets of her tropical timbers. It was recognised that there existed social and economic problems which necessitated each country in the world formulating a policy which should maintain a sufficient area of forest under a conservative management, and this recognition has been growing in force amongst those administrators and specialists who have given attention to this matter in the British Empire. Important, however, as the question of the world's existing resources in timber undoubtedly is, the accompanying and correlated one—the protection from needless destruction of the world's remaining forests, especially in the tropical and subtropical regions, and their proper management—is equally imperative. On three separate occasions this matter has been brought up at meetings of the British Association—in 1850, 1920, and 1926, whilst serious consideration was given to it by foresters interested in tropical forestry at the World's Forestry Conference in Rome in May 1926 (*vide* NATURE, Jan 8, 1927).

As an outcome of the Oxford meeting of the British Association in 1926, Lord Clinton, chairman of the Forestry Subsection, drew up for the Council a short memorandum discussing the destruction of forests on hill slopes, with the well-known after-results, with especial reference to the tropical forests of the Empire. There was nothing new in this memorandum. The subject had been brought up before. But in the hands of so able

a man as the chairman of the Forestry Commission it was believed that the question would receive a sympathetic consideration. The Clinton memorandum was submitted to the Secretary of State for the Colonies, by whom it was communicated to the governors of the various protectorates and colonies.

There was apparently no longer any doubt in the minds of the responsible authorities at the Colonial Office, as there could not have been in those of the Subcommittee of the Empire Conference, that certain practices to which a considerable proportion of the tropical forests of the Empire were still exposed should be stopped, or, at the least, efficiently regulated. The best known of these, by which annually the forests so treated are losing their value or being threatened with total annihilation, are shifting cultivation, excessive grazing of domestic stock, and the annual firing of the forest lands.

As, after the War, the Colonial Office had commenced to recruit trained men for all the various local forest services in the dependencies under that Office, there did not appear to be any reason why the action taken in 1926-27 should not at length meet with a decided and firm response from the several local administrations responsible for these valuable, and in many cases as yet commercially untapped, tropical forests. It may be stated at once that genuine attempts were made towards taking steps to give effect to the Secretary of State's wishes in this matter. Moreover, there were one or two young services which had been inaugurated since the War in which there was no lack of eagerness to commence the steps necessary to grapple with the unchecked and improvident habits of the local populations.

It would be impossible to discuss here the differences which obtain in the ownership, methods of local utilisation, and so forth, of these tropical forests. These vary with colony and dependency. But there is no, or little, variation in the results of the increasingly rapid destruction and deterioration of the forests exposed to the practices above-mentioned. As was seen in India, where formerly a similar state of affairs existed, no forest service in the world can attempt successfully to introduce measures for the regulation, control, and eventual suppression of these injurious acts unless it is strongly supported by the civil authority and, nowadays, by the governor's legislative council, which body will include a number of non-official members.

There can be little doubt that the result of the

active and far-sighted policy of the Colonial Office during the last decade has brought the forests of the protectorates and colonies into a prominent position, and that there now exists throughout the country some knowledge of their importance, and also of possible careers for active young men who make themselves efficient by a university training. To this point it may be said, therefore, that recognition has been given to the need for the conservation and effective management of the Empire tropical forests. But has effective action, necessary in every colony, been taken? Has a forest staff of sufficient strength been recruited? Mere lip service to a recognition of the perils to which a colony will be exposed by the further unchecked destruction of its tropical forest areas, or important sections of them, will not stop the sacrifice, and, each year it is allowed to continue, the destruction, with erosion, etc., proceeds at a greater rate.

Owing to the world-wide financial stringency, government staffs, as also commercial staffs, are so far as possible being reduced and recruitment has been kept at the lowest possible minimum. In the case of the colonial services, the forests have been treated on the same basis as other departments. It may be asked, is this policy, even though the forest department budgets are showing a temporary deficit (for adverse trade immediately reacts on forest receipts), correct or even sound, in the case of a colony possessing capital in the form of undeveloped forest areas subject to abuses and deterioration? Even while admitting that every sound effort should be made towards retrenchment, if the wishes and sentiments expressed by the Empire Conference and ministers on the matter of stopping the long-continued destructive practices of the populations living in, or in the vicinity of, tropical forests were anything more than a pious expression of opinion between 1924 and 1927, how has the position changed? It would appear to be even more vital—the more so since a perusal of the annual reports of the heads of the various forest departments in the colonies and dependencies for the past six years or so will disclose an almost unanimous complaint about the paucity of the staff and the necessity of strengthening it if real conservation was to be introduced, though in a few cases there has been a considerable expansion. In how many of these colonies is the practice of shifting cultivation as rife as it was twenty years ago?

These queries are not put with any idea of a criticism of the Colonial Office authorities. Far

otherwise, as will appear. In a recent article on "Forests and the Economic Crisis" in the *Empire Forestry Journal* (vol 10, No 2, 1931), Sir Roy Robinson deals with what he aptly expresses as the blizzard blowing over forestry. Sir Roy asks what foresters can do, and enumerates five points, covering inaction or action. In one of these he says "If Forestry has proved an easy subject for drastic cuts it is because it had not made sufficient friends. In other words, our educational effort has not yet borne the desired fruits." It would appear that Sir Roy is regarding the matter chiefly from the point of view of forestry in Britain, where, apart from administrators and politicians, an educated forestry opinion in the public would be a strong asset. The position is, however, very different in the case of colonial countries, where an educated public opinion is non-existent, and where the point of view of the administration is the only one to be taken into account. Moreover, Great Britain does not possess any capital in the shape of large areas of undeveloped forests, which is commonly the case in the colonies.

This being so, the fact remains that in spite of the full recognition given to the importance of putting a stop to the destruction of tropical forest, a step which is only possible by having a strong forest department in the colony and backing it up with full official authority, forest staffs are actually being reduced, in a most drastic fashion, and recruitment stopped. In other words, in the interest of a perfectly understood and implicitly believed-in campaign of retrenchment, the development of the capital resources of a colony are being put back by a decade, whilst parts of the capital are subject to annual depreciation. Several instances could be quoted. The case of British Honduras presents some exceptional features and may be regarded as an extreme case, but it has the merit of exhibiting the problem in a manner calling for no expert knowledge upon which to base an opinion.

It is common knowledge that mahogany has been exported from British Honduras for several centuries. Not before 1922 was a small forest department inaugurated. Four years later this young department had six trained officers, the administration being placed under a Forest Trust. The forests were chiefly worked by lumbering companies on leases from government. The young department worked in well with the old methods and had begun to make a most promising headway. The *dénouement* exemplifies the purpose of this article and the question implied

Should a financial deficit in a colony possessing considerable areas of undeveloped valuable tropical forest, at present subject to annual and increasing destruction, justify the abrupt stopping or serious checking of the work in hand or urgently needing being taken up? The following shows what has happened in British Honduras.

Owing to a falling off in forest revenue, the Unofficial Members of the Legislative Council signed a petition on Jan 22, 1929, praying for a general curtailment of the forestry programme and reduction of Forest Trust expenditure. This petition, with comments by the Governor and his advisers,<sup>1</sup> was submitted to the Secretary of State for the Colonies, Lord Passfield. The reply was as follows, and is very instructive.<sup>2</sup>

"In another connection the attention of the Secretary of State had been brought to the disquieting probability that the revenue derived directly and indirectly from forest products will suffer very serious depletion at no distant date. For this reason, in addition to those adduced by the memorialists, he is convinced that the present structure of the Forest Department is heavier than the Colony's economic framework can sustain.

"At the same time, his Lordship is unalterably opposed to any amendment of the legislation governing the constitution, finance, and duties of the Forest Trust. British Honduras has depended upon its forest resources for 300 years, the approaching crisis in output will prove, it is earnestly to be hoped, of temporary duration, and the justification for providing machinery to regulate scientifically, so far as may be, the natural wealth of the Colony is as self-evident now as it was when his predecessor directed the creation of the Trust. His Lordship has accordingly reached the conclusion that the solution of the present financial difficulty is to be sought, not by altering the status of the Trust, but by curtailing its activities and consequent expenditure to the minimum consistent with the discharge of its routine duties, the preservation of its records, and the maintenance of the valuable experimental work already in hand. The adoption of this policy will ensure that when conditions justify the re-enlargement of the scope of the Trust, the nucleus of personnel and the knowledge and experience accumulated will be ready to hand. His Lordship ventures to express the hope that the Unofficial Members of the Legislative Council will exercise the foresight which their position as guardians of the Colony's destinies demands and will lend their willing support in the policy here outlined."

These orders involved a cutting down of the staff, several officers being transferred elsewhere, the loss of the experimental silvicultural work of great promise which had been commenced, for such work is doomed without the eye of the trained officer upon it, and the postponement of the

opening out of considerable areas of unknown forests in this Colony

Lord Passfield may be congratulated on his firm attitude. Nevertheless, until it is recognised that a temporary fall in revenue in the case of inadequately staffed forestry departments should not be met by cutting down expenditure, staff, and so forth, no efficient or rapid progress can be made in the development of potentially rich but imperfectly known forest areas, whilst the delay in introducing an efficient check on indiscriminate acts of destruction is yearly reducing the value of this often irreplaceable asset.

This view of the matter finds strong support in a question connected with Empire timber supplies. In the annual report of the Forest Products Research Board of the Department of Scientific and Industrial Research, the increased interest of the public in Empire timbers is commented upon. The writers, however, stress the opinion that the joint work of the Department and the Empire Marketing Board was not in itself sufficient to cover the necessities of achieving a general development and national use of Empire timbers. Unless production and marketing are closely co-ordinated with research, the work of the Board will be impaired. Amongst other suggestions, the one "that some enlargement of the facilities at the disposal of the Forest Services" is timely. It appears obvious that if production, marketing, and research are to be efficiently co-ordinated, the first step is to go to the fountain-head and maintain or appoint a forest staff of sufficient strength to manage effectively the tropical forest areas in the several colonies.

### Anthropology in Indian Administration

*The Lakhers*. By N E Parry. With an Introduction and Supplementary Notes by Dr J H Hutton. Published by direction of the Government of Assam. Pp xx+640+17 plates. (London: Macmillan and Co., Ltd., 1932.) 36s. net.

MR PARRY'S volume on the Lakhers, for more reasons than one, is a notable addition to the valuable series of monographs on the Naga and other tribes of Assam, published under the direction of the Government of that Province. Apart from its intrinsic merits as a further record of ethnographic facts, owing to the circumstances in which it came to be written, it affords an illustration of the kind of material—the information re-

lating to native life and institutions, the language, customs, and beliefs—which should be mastered as a background for the work of administration. The book, as Mr Parry explains, grew out of a series of brief notes collected with the object of recording those customs concerning which litigation most often arises among the people. The author speedily found, however, that custom was inextricably interwoven with the whole life of the people, and that anything short of a fairly complete knowledge of their daily life would give neither their point of view nor any idea of the practical effect of custom.

A further point in which Mr Parry's book is exceptionally valuable is that it records the life of a people whose institutions have undergone little, if any, serious modification as yet through European administration. It was in 1924 only that the last of the Lakher villages were brought under British control. It is probable that the Lakhers may not have occupied their present situation in the south-east corner of the Lushai Hills for any great length of time. Judging from the number of abandoned village sites, it is estimated that their settlement must have taken place between two and three hundred years ago. Be that as it may, their first contact with the British appears to have been in the forties of the last century, when, as a part of the tribes then known collectively as the Shendus, they were regarded as a powerful and warlike nation—a reputation which appears to have rested to a great extent on lack of knowledge and the difficulty of getting into touch with them, rather than on any very great achievement in their numerous raids. Lakher villages first came under British rule when the Lushai Hills district was formed in 1889. A period of raiding and punitive expeditions followed, culminating in great tribal unrest after the War, which was brought to a close in 1924 with the annexation of the hitherto independent villages lying between Assam and Burma.

Peoples relatively primitive and absolutely untouched by European civilisation, who may be studied in conditions such as have favoured Mr Parry, are becoming increasingly rare day by day. Anthropologists will be duly grateful to the author for seizing the opportunity of making this record of Lakher culture before any fundamental change had taken place. On the other hand, in modern conditions change is rapid, and while the static point of view may well prevail in certain departments of academic study, when it is desirable to apply the results of anthropological science

to a practical problem, as in administration, the dynamic point of view is essential. The questions which then become vital are the quality, degree, and direction of change which are likely to arise as a consequence of contact with European culture, and, of still greater moment, the repercussion of any modification of native custom which may have been introduced by administrative action.

On both these points Mr. Parry has information to record, which is all the more valuable because, administrative action having been confined to a minimum, the changes are few and readily isolated for purposes of study. The Lakhers themselves, though regretting their former freedom of action, admit that British rule has brought advantages in its train, especially in their freedom from ambush and raid, particularly during their beer parties. Now, as they say, they are no longer in danger of "being cut up while they are intoxicated." Although, on the whole, Lakher custom has been scrupulously respected, naturally an end has been put to the taking of human heads, which was customary on the death of a chief to terminate the mourning of his family and village. The mourning custom remains unchanged, but the head of a tiger, wild boar, or wild *mithun* (*Bibos gaurus* or *frontalis*) is now substituted.

In another direction also change has followed administrative action. The position and the importance of the chiefs have been affected by the liberation of the chief's slaves, or dependents, as Mr. Parry prefers to call them. Again, there is a tendency for the villages to become smaller. New settlements are founded by fission from the older with greater frequency than they were formerly, no doubt a result of the sense of greater security now enjoyed. It is probable, however, that in the long run the most lasting effect will follow from the new-found familiarity with and possession of money. This has accrued from the outlet now available for the disposal of the surplus production of rice in the recently annexed villages, where the inhabitants are more industrious and energetic than those of the villages which have been under British administration for some time.

At the risk of laying undue stress upon what is after all only one aspect of Mr. Parry's work, though undoubtedly of great importance, the question of cultural change may be carried a step further. Recent discussion of the place of anthropology in practical affairs has shown a tendency to disparage the claims of comparative study in favour of intensive observation of specific peoples.

While this is not the occasion to attempt a precise definition of the scope and function of the comparative method in such matters, it may be pointed out that a too exclusive attention to a culture as it exists and functions at the moment, without regard to its historic and developmental background, may lead to the neglect of inferences of moment in the study of the effect of cultural impact and the consequent modification, whether favourable or the reverse, in racial character, culture, and social organisation. Indeed it would seem at times, in such discussions as those to which we refer, as though it had almost been forgotten that European civilisation is by no means the only outside influence to which most of the less advanced peoples have been subjected. It is only by the employment of historical and comparative methods that the fact of such contacts, their succession and their results, often far-reaching, can be established.

This important aspect of Lakher culture is discussed in the valuable introduction contributed by Dr. J. H. Hutton, to whose knowledge and counsel the authors who have contributed to this series are so deeply indebted. He points out how the culture of the Lakhers serves to throw light on the stratification of culture of the Assam-Burma Hills. The Assam Hills are, as a matter of fact, in a sense, a key position in the study of cultural distribution in the south-east of Asia and the regions beyond. The Lakhers, it would seem certain, came from various points in the Chin Hills, presumably being pressed forward from the east as were the Lusheis. While some of their customs are typically Naga, and some typically Kuki, others appear to belong to neither of these cultures. Externally they appear to be definitely a Kuki tribe, their language and material culture associating them with the Chins. One interesting example of their affinity with the Kukis may be mentioned. In the legend of the theft of fire by a fly, among the Nagas the object stolen was the fire stick, but among the Lakhers, as among the Kukis, the secret was the flint and steel. The distribution of the institution of a separate house for the young men is also of no little significance. It occurs among the Nagas, but not among the Sema Nagas, although there appears to be a tradition of it. It does not occur among the Kukis, who may be responsible for its absence among the Sema, and the Lakhers follow the Kukis. With both of them, each of the young men takes up his lodging for the night in the house of any young girl to whom he may take a fancy. Yet in his attachment to his village site and to the

graves of his ancestors, Dr Hutton points out, the Lakher is essentially a Naga

In conclusion, it is perhaps permissible to recall that Assam has been singled out of late for favourable comment in the Press for its attitude in recent and still continuing troubled times. Might not the credit, at least in part, have been given to a Government which appreciates, and encourages its officers to adopt, a scientific approach to the problems of administration among a non-European people?

### The Differential Equations of Physics

*Partial Differential Equations of Mathematical Physics* By Prof H Bateman Pp xxii+522 (Cambridge At the University Press, 1932) 42s net

THE main work of mathematical physicists is to represent the sequence of phenomena in time and space by means of differential equations, and to solve these equations. Even the revolution effected by relativity and quantum theory has not changed this fundamental fact. A few years ago, indeed, when the discrete nature of quantum phenomena was being emphasised, it seemed as if differential equations might be replaced in ultimate physics by difference equations. But the discovery of wave mechanics restored the *status quo ante*, and to-day differential equations are more important than ever before.

The differential equations of physics form a class by themselves, though it is not easy to characterise them by a formal definition. In a general way, we may say that physical laws are of the nature of minimum principles (for example, a chain suspended from two points assumes that form which makes the height of its centre of gravity a minimum, a ray of light passing through any number of lenses takes that path which makes the time of passage a minimum, two substances which can change physically or chemically into each other, when placed in contact at a given pressure and temperature, take up that state which makes the thermodynamic potential a minimum, and so on). Therefore the differential equations of physics are essentially the differential equations which solve minimum problems, that is, they are the differential equations which arise in the calculus of variations. With this definition, however, some of the familiar equations, such as the equation of conduction of heat, can only be brought in awkwardly as limiting cases, and perhaps it is best to abandon the search for a definition, and simply to take as

subject matter the equations which have actually been encountered in physical investigations, trusting to exhibit the essential unity of their theory in the course of developing it.

In most cases the problem is to determine a function of the time and the co-ordinates, which in a given domain satisfies some linear partial differential equation of the second order, and also satisfies certain conditions at the boundary of the domain and certain initial conditions corresponding to a given value of the time. The first problem is to find the nature of the initial and boundary conditions which are necessary to determine a solution uniquely. Here the most surprising facts confront the beginner: thus in the case of the equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0,$$

a solution is uniquely determined at points in the interior of a closed curve in the  $xy$ -plane when the value of  $u$  is given at all points of the curve, whereas in the case of the equation

$$\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = 0,$$

which differs from the former only by a change of sign, a solution is uniquely determined when the values of *both*  $u$  and  $\frac{\partial u}{\partial y}$  are given along an *open* curve. The complete resolution of these apparent contradictions by means of the theory of characteristics is one of the most entrancing chapters in mathematics, and as the student proceeds to learn about autovalues (or proper values, or characteristic values, or eigen values, as you please) and autofunctions, about Green's functions and Riemann-Green functions, about the Kirchhoff-Huygens theory of solution by integrals, and the many other properties that are common to large classes of these differential equations, he realises that he is dealing not with a loose collection of examples but with a coherent and unified doctrine which is as fascinating to the pure mathematician as it is important to the physicist.

The need for a substantial modern treatise on this subject has long been recognised, but prospective authors have been deterred by the appalling list of qualifications which the writer of such a book should possess. The first treatise on these equations, written more than a century ago—Fourier's "*Théorie analytique de la chaleur*"—contained more than five hundred quarto pages; since then, more than a hundred thousand pages of memoirs on them must have appeared. An author to-day should know thoroughly the older

mathematical physics—hydrodynamics, elasticity, sound, conduction of heat, thermodynamics, physical optics, electromagnetic theory—and also the newer branches—aerodynamics, general relativity, wave mechanics. Moreover, he must be a first-class pure mathematician, capable of distilling the essence from the gross matter and presenting in a book of reasonable size an orderly account of the ideas and principles and methods by which mathematical physics has been advanced.

The announcement made a year or so ago, that Prof. Harry Bateman—Senior Wrangler in 1903, fellow of Trinity College, Cambridge, and now professor of mathematics at the California Institute of Technology—had undertaken this task, was therefore received with a lively hope and interest. For Prof. Bateman is one of the most eminent living scholars in this domain. The work, which is now published, is one of the gigantic blue-bound tomes to which the Cambridge Press has accustomed us. xxii + 522 pages, and highly condensed at that. An examination in detail fills one with admiration for the author's skill and learning. He seems not only to have read everything, but also to be capable of proving any theorem more neatly than its original discoverer. The analytical dexterity which was fostered by the old Cambridge tripos was never more brilliantly displayed.

Unfortunately, there is another side to the picture. It is not possible to mention the great merits of the book without admitting that it has one serious defect. This is, the lack of what one may call architectural structure. I mean, of design, selection, and arrangement. The author seems to pour out his treasures pretty much as they come into his mind, and presents his results without clearly disentangling the essential points on which attention should be focused, and without ordering the whole on any recognisable plan. The trouble is, I think, partly due to the fact that he does not seem to have quite made up his mind what class of readers he is writing for, but ranges over the whole breadth of his own erudition. At one time we hear about Lebesgue integrals, at another technological details about the moisture in the heartwood of a piece of Sitka spruce. In one place he proves the ordinary Lagrange's equations of motion in dynamics. But is it likely that anyone who was not already acquainted with Lagrange's equations would tackle a 500-page book on the partial differential equations of mathematical physics?

The early chapters are the least satisfactory, because it is there that we notice most the failure

to set leading principles in a high light. When the author gets to the middle of the book, and displays his analytical skill successively with polar co-ordinates, cylindrical co-ordinates, ellipsoidal co-ordinates, paraboloidal co-ordinates, and toroidal co-ordinates, we feel that we are reading the work of a master.

One wishes the author had treated some things more fully, for example, the theory of characteristics (on which §§ 1.92 and 2.24 are scarcely adequate), or the general theory of conservation laws (on which he gives only some results set as examples on p. 183), or the interesting differential equations which occur in general relativity (particularly in connexion with the electromagnetic field), or the differential equations of wave mechanics. But one feels that criticism is ungracious for the book is indeed unique, an invaluable work of reference, a thesaurus which no college or university library, and no working mathematical physicist, can afford to be without.

I have noticed only one error, namely, on p. 181, where the introduction of electromagnetic momentum is attributed to Abraham and Poincaré (whose papers appeared in 1900–2). The credit for this important discovery properly belongs to J. J. Thomson, who published it in 1893 in his "Recent Researches in Electricity and Magnetism".

### Chemical Elements at a Glance

*Chemischer Handatlas. Anorganische Chemie unter besonderer Berücksichtigung von Atomphysik und Atomchemie. Graphische Darstellung der Eigenschaften chemischer Elemente und ihrer Verbindungen nach der Anordnung des natürlichen Systems der Elemente auf 60 vielfarbigten Karten mit Beschriftung in deutscher, englischer, französischer, italienischer, spanischer Sprache nebst ausführlichem, erläuterndem Texte.* Von W. Walter Meissner. Pp. xi + 77 + 60. (Braunschweig, Berlin und Hamburg: Georg Westermann, 1931.) 38 gold marks.

THE modern developments of the theory of atomic structure are intimately connected with the periodic system of the elements, and it has become increasingly necessary and important to have available some scheme in which the various properties of the elements can be exhibited as a connected whole, so that comparison between values for the elements can be made. This suggests that the properties concerned should be represented by some kind of symbols, the size of which should

convey an idea of the magnitudes. The "Atlas der physikalischen und anorganischen Chemie" of A. von Antropoff and M. von Stackelberg, published in 1929, carried out the scheme in a number of loose sheets, printed in black, and accompanied by a separate volume of text. The atlas of Meissner, which is more convenient in size, and is bound together as text and plates in one book, carries the systematisation a step further, since colours are employed, and, in addition to lines of varying lengths, there are figures of various shapes denoting special properties.

Although at first sight the result may seem a little complicated, a few minutes spent over the book will enable the reader to grasp the general plan and to understand without difficulty the symbolism used. The text is in German, the other languages being used only for the headings of the charts. A great amount of information is compressed into the text, and, what is more, references to the original literature are included. The main interest is in the direction of atomic structure, but the charts cover a wide field, including such matters as geographical distribution, a history of the chemical elements (a valuable and unusual feature), solubilities, and even analytical separations. It is clear that the amount of information contained in the atlas is really very considerable, and the book may be warmly recommended as likely to be most useful not only to chemists but also to workers in other sciences who wish to obtain an impression of modern chemical science, and to follow this up by reference to the original literature.

Among such a mass of detail errors are unavoidable, and it is to be hoped that in the preparation of future editions a close revision of the whole will be carried out, since the value of such a compilation is seriously affected if it is not absolutely accurate. In Table 48, for example, two values (143.1 and 143.9) are given for the heat of formation of magnesium oxide, and the formula of fluorine oxide is printed incorrectly. The scale of solubilities in Charts 52-57 is only half the correct size (as is pointed out in the list of errata on p. 77), and this should be put right in future editions. There are other similar errors, and the book would be improved by a careful overhaul. The text is also, for English readers, likely to prove rather difficult by reason of the unusually long and involved sentences and long words. This is no doubt a consequence of the necessity for condensation in the text, which has enabled a large amount of information to be given opposite each plate.

This atlas will prove of great use to teachers and

lecturers, since it provides much material in a brief form suitable for incorporation into lecture courses. The charts are well conceived and, on the whole, well executed, and the advantage of having the text bound together with the charts and facing them is obvious. The price is rather high.

### Short Reviews

*Gmelins Handbuch der anorganischen Chemie*  
Achte vollig neu bearbeitete Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft. Bearbeitet von R. J. Meyer. System-Nummer 8. Jod. Lieferung 1. Pp. 244. 37 gold marks. System-Nummer 45. Germanium. Pp. xviii + iii + 62. 13 gold marks. System-Nummer 59. Eisen. Teil B, Lieferung 4. Pp. 657-872. 28 gold marks. (Berlin: Verlag Chemie G. m. b. H., 1931.)

THE first part of the volume on iodine deals with the element itself, consideration of its compounds being reserved for the second part. The authors claim, in an introductory note, to have produced not only a comprehensive survey but also a critical monograph on the subject. Elaborate details of the occurrence of iodine are given, not only in various minerals, fossils, and natural waters, but also in a multitude of different species of plant and animal life. The iodine content is in many cases exceedingly small, so that in cases where the milligram is too large a unit for convenience, the symbol  $\gamma$  is used to denote one-thousandth of this amount. The physical and chemical properties of the element are carefully surveyed and a lengthy section deals with the action of various solvents upon it. An interesting special feature of this volume is the commercial section, which is illustrated with graphs showing the annual output of iodine in Chile since 1868 and in Java since 1892. The world production in 1929 is given as 1650 tons, of which only about thirty tons were produced in Great Britain.

The literature on germanium has been reviewed up to May 1931, but the work of Muller, Pike, and Graham in 1926 on the preparation of the pure metal, its melting point *in vacuo*, and its volatility in various gases, has been overlooked. The volume opens with an account of Mendeléeff's prediction of the existence of eka-silicon, the discovery in 1885 by Weisbach of the mineral argyrodite, the analysis of the latter by Winkler, and the ultimate recognition of the new element which it contained. The relationship of germanium to carbon and to silicon is clearly brought out in the volume, and a list of organo-germanium derivatives is tabulated.

The fourth section of part B of the volume on iron completes the survey of that element and deals chiefly with ferrous and ferric ferrocyanides, ferrous and ferric ferricyanides, other complex cyanides, and sulphocyanides of iron. Then follows an account of the compounds of iron which contain silicon, phosphorus, arsenic, antimony, and bismuth. The volume concludes with a lengthy section upon the general reactions of ferrous and ferric compounds which can be used in analytical work.

*Die elliptischen Funktionen von Jacobi. Fünfstellige Tafeln, mit Differenzen, von  $sn\ u$ ,  $cn\ u$ ,  $dn\ u$  mit den natürlichen Zahlen als Argument, nach Werten von  $m$  ( $=k^2$ ) rangiert, nebst Formeln und Kurven.* Von Prof L M Milne-Thomson. Pp xiv + 69 (Berlin Julius Springer, 1931) 10 50 gold marks

THE scope of this work is explained by its title. The author has succeeded in condensing into a very small space three quite adequate tables of double entry, which should be very useful to all who need numerical values of elliptic functions. Entries to five places of decimals are sufficient for nearly all practical purposes, and, by restricting the entries in this manner, the author has made it possible to interpolate not only (vertically) for  $u$ , but also (horizontally) for  $m$ , the vertical interpolations are facilitated by the insertion of a table of first differences.

The tables are beautifully printed, the only defect in them which has been noticed is a dropped digit on p 14. An introduction of eight pages gives a compact set of integrals and other formulae, which add to the value of the book. Tables of elliptic functions, being essentially tables of double entry, are extremely scanty in number, the only existing tables with which these can reasonably be compared are Glaisher's much more elaborate tables of the theta functions, which are, as yet, unpublished. The publication of Glaisher's tables will not, however, make Milne-Thomson's tables superfluous, since elliptic functions can be obtained from Glaisher's tables only as the quotient of two entries.

We welcome with enthusiasm the volume under review. Before its appearance, on the occasions (not, it is true, very numerous) on which numerical values of elliptic functions were needed, the reviewer's usual procedure was to take the Smithsonian Tables and to waste perhaps half an hour in trying to unravel the mysteries of their notations, then to put them aside in exasperation and to compute the values required by means of  $q$ -series. The present work will not be the cause of similar trials of patience.

G N W

*Anatomy in the Living Model: a Handbook for the Study of the Surface Movements and Mechanics of the Human Body and for the Surface Projection of the Viscera, etc.* By Prof David Waterston. Pp xvii + 255 + 16 plates (London Hodder and Stoughton, Ltd, 1931) 25s net

WE welcome the appearance of Prof Waterston's useful manual of surface anatomy, which is illustrated with numerous figures in monochrome and colour by that excellent draughtsman the late Mr J T Murray, whose death just after the completion of the beautiful drawings in this book is a serious loss to anatomy. The book gives a careful account not only of the modelling of the body and the relations of the surface markings to the deep structures, but also to the texture of the skin and what can be learned in the living from its reactions to stimuli.

It is unfortunate, however, that a book dealing primarily with the living subject should omit any

adequate reference to the chief means now at the service of the anatomist for studying the living—namely, X-ray photography. The author of the present book admits this omission, but excuses it by the surprising statement that "X-ray examination covers too wide a field and is too specialised a matter to be included here." But the information obtained by the use of X-ray photography cannot be regarded as "too wide" or "too specialised" to be expressed in the drawings. Although the work is dealing with the *living* body, the most beautiful of Mr Murray's drawings (Plates XI to XIV and Figs 70 to 74) obviously represent in the *dead* body conditions which profoundly differ from those which obtain in the living.

*Recent Advances in Organic Chemistry.* By Prof Alfred W Stewart. Sixth edition. Vol 1 Pp xii + 429. Vol 2 Pp xii + 432 (London, New York and Toronto Longmans, Green and Co., Ltd, 1931) 21s net each vol.

AS compared with the fifth edition (see NATURE, Dec 24, 1927, p 908), the new volumes have been augmented by 42 pages and 50 pages respectively, and two plates illustrating space-models of hexamethylene and reduced naphthalene rings have been inserted. The general plan of the work remains unaltered. New matter, illustrating important researches of the last few years, has been incorporated: thus, vol 1 contains a chapter on the polymethylenes and some large carbon rings, in which noteworthy work by Ruzicka and his collaborators is discussed, and vol 2 includes an account of di- and tri-terpenes (the camphorenes and squalenes), the decalins and other fused ring-systems, and the diphenyl problem. The new edition will continue to lighten the labours of advanced students and research workers who are interested in the fields which Prof Stewart has selected for treatment in this valuable publication. For the work to remain true to its title, however, we suggest that some of the older and more familiar material ought to be replaced by sections on cholesterol, vitamins, and other subjects of current importance, the account of electronics in organic chemistry also calls for expansion. J R

*Outline of Comparative Embryology.* By Prof Aute Richards. Pp xvi + 444 (New York: John Wiley and Sons, Inc., London Chapman and Hall, Ltd, 1931) 30s net

THE first part of this book deals with those embryological processes which are common to most of the higher animal forms, and presents in assimilable form the accepted views on cleavage, germ layer formation, the egg, and embryonic membranes, including the placenta. The consideration of various invertebrate forms is based largely on the work of Korschelt and Heider. The second part of the book deals with modern problems in embryology, and presents the modern aspects of asexual reproduction, parthenogenesis, and polyembryony with clarity. The historical aspect is well maintained, and the recent expansion of experimental embryology is admirably incorporated.

## Canadian Water Power Development in 1931

By Dr BRYSSON CUNNINGHAM

THE development of hydro-electric power in Canada continues to make progress at a striking rate, the figures published in the latest returns of the Dominion Government<sup>1</sup> showing an increment of more than half a million installed horse power for the year 1931, as compared with rather less than 400,000 horse power for the preceding year. Looking back over a period of twenty years, it can be seen that the aggregate increase to date is just five million horse power, so that the actual rate of increase for the past twelve months stands considerably above the average. The total development to the end of the year 1931 is 6,666,337 horse power, or about 15½ per cent of the total recorded water power resources available.

Figures of such magnitude are difficult to realise by any effort of mental vision. Translated into terms of coal fuel at the most recently determined equivalent of 5¼ tons of coal per horse power in continuous operation throughout the year, the existing installations of the Dominion represent a potential saving in coal consumption of approximately 35 million tons per annum, an economy of notable dimensions, especially in a country where nearly all coal has to be imported from abroad. Measured in terms of population, there is 644 developed horse power per 1000, and in one province (Quebec) the proportion is 1 081 horse power per head. On the financial side, the capital invested in the various undertakings is estimated at more than 1514 million dollars. The accompanying table gives a detailed analysis

of the allocation of power among the leading industries for each of the provinces of the Dominion.

The distribution of energy among the provinces is, as might be expected, far from uniform. Quebec and Ontario, industrial regions of high productivity, possessing no natural deposits of coal within their borders, make by far the largest demands for

FIG 1—The 'obelisk' for damming the main stream of the Saguenay River in course of construction. By courtesy of the High Commissioner of Canada.

DEVELOPED WATER POWER IN CANADA. DISTRIBUTION  
BY PROVINCES AND INDUSTRIES

power, and, fortunately, possess correspondingly large hydraulic assets. Quebec has an aggregate installation of 3,100,330 horse power, of which 382,200 horse power was provided last year. Ontario's aggregate is 2,145,205 horse power, of which 58,200 horse power was last year's contribution. These two provinces stand far ahead of all the others, the nearest to them being British Columbia with a present installation of 655,992 horse power. The total water power resources of the Dominion, estimated on the basis of the information available at the present time, are of the order of 43 or 44 million horse power.

To review the development of the respective provinces would take too long, and would involve a recital of sites and powers which would occupy more space than can be spared. From the con-

siderable number of installations, the following example is selected for brief notice, as it exhibits some features of remarkable interest. It is the largest of the undertakings brought to completion during the twelve months under review, and it is notable alike for the gross capacity (260,000 horse power) of the station and for the magnitude (65,000 horse power) of each of the four units of operating plant.

Chute à Caron is the name of a fall on the river Saguenay, in the province of Quebec, which runs from Lake St John and discharges into the St Lawrence. An earlier development at Isle Maligne,

second is known as the Shipshaw project. The former has involved the construction of a massive concrete dam across the river Saguenay, just above the Chute à Caron rapids, and the temporary diversion of the river through the power-house until such time as the Shipshaw works are completed, when the river will be restored to its former bed and the Chute à Caron station will be used merely as a stand-by. Temporarily, by the development of a fall of 151 ft, it renders available a total of 260,000 h p, while the ultimate achievement of the Shipshaw project, with its comprehensive fall of 205 ft, will raise the total to a million h p.

FIG 2.—Damming the main stream of the Saguenay River. By courtesy of the High Commissioner of Canada.

at the head of the same river, has previously been noticed in NATURE.<sup>2</sup> The Isle Maligne installation is the property of the Quebec Development Company, and has a capacity of 540,000 horse power. Completed some five years ago, it represents the exploitation of about one-third of the total fall of the Saguenay River below Lake St John, that is to say, from 90 ft to 119.5 ft, according to the water level of the lake. In the original programme of development for the river, it had been contemplated that the remaining 208 ft of fall would be developed in a single step, with an initial capacity of 800,000 h p, and an ultimate capacity of 1,000,000 h p. The delay involved in the single-step programme made it desirable, on economical grounds, to take advantage of a combination of natural conditions which permitted of more convenient development in two steps. The first of these is the Chute à Caron undertaking, and the

One of the most remarkable features\* of the undertaking, probably unique in engineering practice, was the instantaneous damming of the main stream, which is about 100 ft wide by 35 ft deep, by means of the fall of a monster block, or monolith, of solid reinforced concrete, weighing 10,950 tons. The 'obelisk', as it was termed for convenience (Fig 1), was built in a vertical position on a small rocky island connected to the south bank of the river by a coffer-dam. It had a height of 92 ft, a width of 45 ft, and a depth of 40 ft at the centre to the underside of its curved base. It contained 5400 cubic yards of concrete and 50 tons of steel reinforcement. The pedestal on which it was poised before its overturn, was made in the form of two piers, the smaller of which, on the river

\* The particulars relating hereto are taken from an extract of a paper read by Mr J. W. Rickey, before the Engineer Society of Western Pennsylvania, and published in the *Canadian Engineer* of Jan. 26, 1932.

side, was, at a prearranged moment, demolished by blasting, allowing the unbalanced obelisk to roll forward over the cylindrical surface of the remaining pedestal and fall prone into the torrent, in this way completely arresting in a few seconds a volume of nearly 2000 cubic feet of water racing at a velocity of about 30 ft per sec. A view of the incident is given in Fig 2.

An operation of so unprecedented a character involved certain intricate problems, the calculated solutions of which were checked by the construction of a model to a scale of 1/50 in the Hydraulic Laboratory of the Carnegie Institute of Technology, Pittsburgh. Recording devices on the model gave practical demonstration of the effect of the water

cushion on the impact, and of the dynamic stroke of the stream against the obelisk before reaching the bed. It is satisfactory to learn that the whole operation of overturning the huge mass was carried through without a hitch of any kind. After the explosion of the charge of dynamite, the obelisk fell exactly in accordance with the calculations, and landed on the river bed within an inch of its destined position. The impact recorders showed that almost the whole (99.6 per cent) of the energy of the falling mass was absorbed by the cushion provided by the water.

### The Hereditary Transmission of Acquired Characters\*

By Prof J B S HALDANE, F R S

IN another series of experiments which MacBride quotes, Harrison induced a race of the willow gallfly, *Pontania salicis*, to change its food plant from one species of willow to another. He first showed that a race taken from *Salix phylicifolia*, when given the choice of 21 species or subspecies of willow, confined themselves almost wholly to the original plant and to the related *Salix Andersoniana*. However, in addition, 3.5 per cent of the eggs were laid on *Salix rubra*. In two out of three years the galls on this latter plant failed. In one year seven of them reached maturity. In a second experiment, Harrison let loose gallflies from *Salix Andersoniana* in a patch of willows consisting entirely of *Salix rubra*. The eggs were perforce laid on the latter, and the large majority of the galls aborted in the first two years, but fewer in the next two. At the end of the fourth year, *Salix Andersoniana* was planted near the patch, but in the course of two years no galls were formed on it.

There can be no question of the importance of Harrison's demonstration that a race of insects can in this way acquire a new character. But the reasons for this event are not so clear. Wheeler (who as a Lamarckian cannot be accused of bias) regards the choice of food in which to lay eggs as determined largely by memory of larval surroundings, and particularly smells. The other factor in successful colonisation is the ability of the larva to eat and digest its food. Now, as in the first years most of the galls aborted, it would seem likely that the larvæ were being very stringently selected. The capacity to grow on *Salix rubra* is rare in the original race. Only in 7 out of 57 galls on it did the larvæ mature. Until a definite proof of Lamarckian inheritance has been given, in any case, we are justified in putting down the observed facts to selection, perhaps aided by individual (not racial) memory. We know that variation occurs in man with regard to idiosyncrasy to foodstuffs, and there is evidence that it is inherited, the same is very probably true of insects.

\* Continued from p 819

Finally, MacBride cites Metalnikoff's experiments on the acquired immunity of the moth *Galleria mellonella* to a bacillus. I quote one sentence from MacBride's account: "After three or four days the survivors were counted and allowed to develop and become the parents of the next generation." Unless *Galleria*, unlike men, mice, and other species investigated, does not possess any innate variability in its resistance to disease, there has clearly been stringent selection, and we need not be surprised that a relatively resistant race has been developed.

I pass over several other cases where apparently Lamarckian effects have been due to infection, and Kammerer's experiments, which terminated in his suicide, to the very remarkable results obtained by McDougall on rats. Unlike the other workers here cited, he began with an approximately pure line of rats which had been inbred for many generations. He also took considerable precautions to avoid selection. Unfortunately, the procedure of training was twice changed during the experiment, so I shall only describe the latter half.

The rats at an age between three and four weeks were dropped into a tank of water in which two turnings led to platforms covered with wire gauze by which they could emerge. One of these (alternately on the right and left) was illuminated, and a rat stepping out of the water on to it received an electric shock. Each rat was dropped in six times daily until it learned to avoid the illuminated platform. Learning was regarded as complete when this occurred on twelve successive trials. After twelve generations, all but one of which had been trained under slightly different conditions, but had shown a decided increase in educability, the procedure was finally standardised. In nine generations the average number of errors fell from 80 to 25, and the number made by the best rat from 42 to 3. In an experiment on a related group, the number of errors fell from about 170 in the first generation to 114 in the fifth. Finally, the worst performers were selected during two generations, but in spite of this, the time needed for training fell.

To obviate the possibility of tradition, mothers of a slightly trained stock were mated first with slow-learning and then with quick-learning males. The first mating gave an average number of 166 errors, the second of 62. The character acquired appears to be caution. It does not seem to be general intelligence, general timidity, or a specific fear of the bright gangway.

One very important point which emerged was that the progeny of the trained rats at first showed much greater variation in learning power than those of the untrained. If capacity for learning is inherited within the group (which could be ascertained or disproved from McDougall's records were they published in full), the process of change would have been greatly accelerated if selection had also taken place, if in fact the spread of acquired variations through the population had been aided by selection, as Darwin thought was the case in ordinary evolution.

Now, while it is clear that McDougall's experiment is in a class by itself, it has been criticised by Sonneborn, among others. Sonneborn notes that the intensity of the shock varied considerably and was not measured, and that McDougall found that rats subjected to light shocks took nearly three times as long to learn as when the shocks were heavy. So a progressive increase in the shock intensity could account for McDougall's results. He further points out that, if the method of choosing two rats 'at random' from a litter was to take the first two available in a cage, this would tend to select rats of a particular psychological disposition. Various other criticisms can be made. Hence it would seem that, while one must admit that McDougall has made out a *prima facie* case, a suspension of judgment is not unreasonable before we regard him as having demonstrated a principle in evolution which is unsupported by other evidence of the same calibre. It is, moreover, worth noting that in another experiment, broken off after four generations, McDougall found that the time needed for training increased in successive generations. He put this down to an increase in timidity, thus contriving to eat his cake and have it.

If we reject Lamarckism, we are, I think, left in the position termed neo-Darwinian, but concisely stated by Lucretius, one of the greatest minds of all history, two thousand years ago (I owe the quotation to Dr C. D. Darlington)\*. Genes, the *genitalia corpora* of Lucretius, reproduce themselves at each cell division, and are handed down from parent to offspring. The genes in an organism determine how it will develop and behave in a given environment. The process of reproduction

of the gene is not perfect. Occasionally a gene produces another gene of a different type. This process is called mutation, and has never been shown to be adaptive, still less to perpetuate an acquired habit. Changes in the number of genes (for example, by doubling the chromosome number) also occur. Evolution is due to the fact that only a few of the possible combinations of genes survive. Were this not so, it would have been a mere orgy of variations without any particular trend.

I should like emphatically to protest against the view that the contest between Lamarckism and neo-Darwinism has anything to do with that between vitalism and mechanism. It would be quite possible to explain McDougall's results on thoroughly materialistic lines if the increased use by his rats of certain parts of the brain liberated specific substances into the blood, and these substances acted on the genes concerned with the elaboration of cerebral structure. Again, the neo-Darwinian may be a thorough-going vitalist, regarding each gene as an elementary living thing, contributing to the communal life of the cell and the federal life of the organism. He differs from the Lamarckian in believing that the gene has a very high degree of autonomy. There is no more reason to describe him as a mechanist than to dub a man an anarchist if he thinks that Parliament should not reverse the decisions of the London County Council. Similarly, a Lamarckian can be a vitalist, and a Darwinian a mechanist, or, like myself, he may refuse to take either point of view.

Further, it is often stated that a refusal to admit that conscious purpose has played any important part in evolution is a gloomy and even immoral point of view. McDougall writes of "the Cimmerian darkness in which Neo-Darwinism finds itself", and I admit that a theory which (like that of stellar structure) is largely based on integral equations is inevitably lacking in popular appeal. Nevertheless, the exact opposite seems to me to be the case. It has taken about a thousand million years for evolution to produce man, and the process has not only been slow but also often cruel. If mind had been an important evolutionary agent, there would be some ground for pessimism. If, on the other hand, it is only in our own time that the purposive guidance of the evolutionary process is becoming possible, then the outlook is altogether brighter. But if this is so, it is all the more our duty to examine as critically as possible the various evolutionary theories and to reject those which do not rest on a solid basis of observation.

From the human point of view the implications of the neo-Darwinian point of view were forcibly stated by the prophet Ezekiel (ch 18, v 2).

"What mean ye, that ye use this proverb concerning the land of Israel, saying, The fathers have eaten sour grapes, and the children's teeth are set on edge? As I live, saith the Lord God, ye shall not have occasion any more to use this proverb in Israel."

If we accept this point of view, each of us starts

\* The quotation from Lucretius is a moderate statement of his doctrine. He sometimes stated it in an obviously false manner, for example, in his "Histoire naturelle des animaux sans vertèbres" we read:

"Quatrième loi. Tout ce qui a été acquis, tracé, ou changé dans l'organisation des individus, pendant le cours de leur vie, est conservé par la génération et transmis aux nouveaux individus qui proviennent de ceux qui ont éprouvé ces changements."

For example, children acquire a full knowledge of their parents' language without education, and Jews are born circumcised. Lamarck's mistaken views on heredity do not, of course, lessen the greatness of his work on evolution. But it is unfortunate that many French biologists tend to exalt Lamarck and neglect another great Frenchman, de Vilmorin, whose discovery of pure lines laid the foundation of modern genetics.

afresh with the genetical constitution derived from his or her parents. The way in which his ancestors have employed their talents is irrelevant. The slum child, if of sound constitution, will not be handicapped by the bad environment of his parents provided he is transplanted early enough. Nor,

on the other hand, are the effects of university education inherited. By the process of death and reproduction the species throws off some of the intolerable burden of the past. Evolution is thus possible for the race at a rate and to an extent which would be impossible for the individual.

### Electrical Conductivity of Metals at the Lowest Temperature \*

WITH the fairly large supplies of helium now available it is comparatively easy by the liquefaction of this gas to reach temperatures so low as  $1^{\circ}\text{K}$  ( $-272^{\circ}\text{C}$ ). At this low temperature a few of the metals become perfect conductors of electricity. Most of them, however, still exhibit, when so cooled, a decreasingly small but still quite measurable resistance to the passage of a current.

In 1911, Kamerlingh Onnes at Leyden, while carrying out researches at low temperatures with the aid of liquefied helium, discovered that mercury, when cooled down and solidified with liquid helium, suddenly and abruptly at about  $4.2^{\circ}\text{K}$  became what is now designated as a superconductor of electricity. At temperatures below  $4.2^{\circ}\text{K}$  mercury offers no measurable resistance to the passage of a current. Currents of electricity started in a ring of mercury in the superconducting state will continue apparently undiminished in intensity while the metal is in that state. The duration of these persistent induced ring currents is limited only by the length of time the cooling agent, liquid helium, will last. Other metals that exhibit this superconducting property if made sufficiently cold are lead, tin, indium, gallium, thallium, tantalum, titanium, and niobium.

The transition temperature for the passing of a metal from the ordinary conducting to the superconducting state is not a constant but varies with the metal. For mercury it is  $4.2^{\circ}\text{K}$ , for lead  $7.2^{\circ}\text{K}$ , tin  $3.72^{\circ}\text{K}$ , tantalum  $4.5^{\circ}\text{K}$ , thallium  $2.39^{\circ}\text{K}$ , indium  $3.4^{\circ}\text{K}$ , gallium  $1.07^{\circ}\text{K}$ , and niobium  $8.2^{\circ}\text{K}$ . Some alloys and chemical compounds of the metals also exhibit the superconducting phenomenon. Copper sulphide, for example, does so, though neither of the constituent elements is a superconductor. The nitrides and carbides, borides and silicides of several of the metals such, for example, as molybdenum, tungsten, tantalum, zirconium, and niobium, are also superconducting at sufficiently low temperatures.

The addition of metals of the bismuth group to superconducting metals has been found, speaking generally, to raise their transition temperature. Bismuth added to lead raises the transition temperature from  $7.2^{\circ}\text{K}$  to  $8.8^{\circ}\text{K}$ , carbon raises that of niobium from  $8.2^{\circ}\text{K}$  to  $10.5^{\circ}\text{K}$ . Gold alloyed with bismuth becomes superconducting at  $1.94^{\circ}\text{K}$ , whereas neither constituent alone becomes superconducting even at the lowest temperatures obtainable.

The application of mechanical stresses such as

those of torsion and tension raise the transition temperature of a superconducting metal, but the application of a magnetic field delays the appearance of superconductivity in a metal, and causes it to appear at a lower temperature than normally.

If a metal in the superconducting state be subjected to a gradually increasing magnetic field, a critical field strength is reached when electrical resistance reappears in the metal. The strengths of the critical fields required for different superconductors vary; an alloy of bismuth and lead, for example, at  $1.2^{\circ}\text{K}$  requires a magnetic field of 20,000 gauss to restore the property of electrical resistance, while metallic thallium at the same temperature requires a field of only 15 gauss.

Since the electrical resistance of superconducting metals is zero, no heat is produced when electrical currents are passed through them. Currents of high intensity can therefore be passed through superconducting wires of small diameter without melting them. Electric currents of more than 1000 amperes have been so obtained in wires of small cross-section. The factor that imposes a limiting value upon the current strength is the magnetic field set up in the wire by the current itself. A critical value is reached when resistance is restored to the wire by the magnetic field.

Interest in the problem of superconductivity in metals recently received a stimulus through the discovery by Prof. McLennan and his collaborators that the transition temperatures with alternating electric fields applied are not the same for superconducting metals as when direct currents are passed through them. In a series of experiments with a coil of tin wire, drawn to a diameter of 0.3 mm, it was found that with direct currents the resistance of the coil began to decrease abruptly at  $3.76^{\circ}\text{K}$  and disappeared completely at  $3.70^{\circ}\text{K}$ . Experiments with the same coil with currents of frequency  $1.1 \times 10^7$  per second gave for the corresponding temperatures  $3.67^{\circ}\text{K}$  and  $3.61^{\circ}\text{K}$ , that is, superconductivity did not begin to appear until a temperature was reached that was below the one at which it was complete in the case of the direct current experiments. Further experiments with higher frequencies revealed depressions of the critical transition temperature, increasing in amount with the frequency. Extrapolation of the transition temperature-frequency curve, which appeared to be linear for the higher frequencies, gave  $10^9$  per second for the frequency corresponding to  $0^{\circ}\text{K}$ .

With tantalum wires, results were obtained similar in character to those found with wires of tin and of lead. Experiments with tin wire coils

\* Substance of the Friday evening discourse delivered by Prof. J. C. McLennan, F.R.S., at the Royal Institution on June 3.

showed that the observed depression of the critical temperature was not dependent upon the magnitude of the high frequency currents in the coils, and was therefore attributable neither to the heating of the coils above the temperature of the surrounding liquid helium nor to the effect of the magnetic field of the currents. Experiments with wires of different sizes made with currents of the same frequency showed that the depression of the transition temperature was not a direct function of the skin effect. It would appear, then, to be a function of the frequency of the current in the metal alone.

The conclusion is drawn that polarisation and orientation phenomena are involved in the production of the superconducting state in metals, and that this electrical state is somewhat analogous to the saturated magnetic state obtainable with ferromagnetic metals. A new road of attack upon the problem of superconduction in metals seems to be opened up by the discovery of this frequency disturbance of the critical transition temperatures.

In the course of his lecture, Prof McLennan gave

a demonstration of the persistence of an electrical current in a metal at the temperature of liquid helium. Prof W H Keesom, who succeeded Kamerlingh Onnes at the Cryogenic Laboratory at Leyden, liquefied a quantity of helium during the morning of June 3. This helium was collected in a large Dewar flask supported in a second Dewar flask filled with liquid air, these two were then supported in a third Dewar flask also filled with liquid air. A small ring of lead about an inch in diameter and about an eighth of an inch in cross section was placed in the bottom of the inner flask immersed in the liquid helium and a current of several hundred amperes was induced by an external magnetic field in this lead ring. Prof Keesom's assistant, Mr Flim, carrying the Dewar flasks, was brought by aeroplane by Colonel the Master of Sempill to the aerodrome at Hanworth and thence by motor car to the Royal Institution in time for Prof McLennan's discourse. By this means, liquid helium and an electric current in a superconducting metal were exhibited for the first time in England.

### Obituary

THE HON MRS HUIA ONSLOW

MRS ONSLOW was a distinguished plant biochemist. As Muriel Wheldale, she went to Newnham College, Cambridge, in 1900, from King Edward's School, Birmingham, and in due course obtained a first class in Parts I and II of the Natural Sciences Tripos. She was appointed to a Bathurst Studentship in 1904, and afterwards became a research fellow and associate of her College. For two years she was a research worker at the John Innes Horticultural Institution. In 1926 she was appointed to a University lectureship in plant biochemistry at Cambridge.

Mrs Onslow's scientific work was devoted mainly to two lines of inquiry: first, to the chemistry of anthocyanins, with special reference to the behaviour of these pigments in the genetics of flower colour; secondly, to the nature of the oxidase systems of plants. During the years 1903-9 she made a very thorough study of colour inheritance in *Antirrhinum majus*. As a result of this study she advanced the original suggestion that anthocyanins are formed from the glucosides of flavones, her view at that time being that the conversion was due to the action of an oxidase. In 1913-14 she isolated and studied chemically the antirrhinum pigments. This work was done before the classical studies of Willstätter were published, and though her views have not all been confirmed in detail, she was a pioneer in the subject, and in particular she was one of the first to discuss in acceptable terms the factors of inheritance from a chemical point of view.

To the study of plant oxidase systems Mrs Onslow devoted much labour and made in particular one contribution of much interest. Bach and Chodat had shown that the tissues of some plants yield extracts capable of directly inducing certain oxidations such as the blueing of guaiacum, while

others do so only after the addition of a peroxide. The latter were held to contain a peroxidase enzyme alone, while the former contain a second factor capable of replacing the peroxide. Mrs Onslow showed that this second factor is a catechol derivative, and found after an exhaustive study that it was present in all plants of the former class and absent in those of the latter. She then showed that plant extracts can convert monophenolic compounds, for example, *p*-cresol, into diphenolic compounds—an observation of importance to the later development of the subject. In recent years she was engaged in supervising an exhaustive research upon the respiration of apples, the work being done in relation with the problems of cold storage.

In 1916, Mrs Onslow published a monograph on the anthocyanins, and in 1931 appeared Part I of her "Principles of Plant Biochemistry". Of the latter, the second part is not published. Her last contribution was the review of the recent literature on anthocyanins which appeared in the issue of NATURE of April 23.

In 1919 she married the Hon Huia Onslow, whose devotion to scientific and artistic labours after almost complete disablement by a serious accident won deep admiration from all who were privileged to know him. The companionship of one who shared his interests and understood his intellectual needs added happiness to his latest years.

Mrs Onslow was deeply devoted to the subject of her study, and having a gift for clear exposition, she taught it with great success. She had a passionate love for travel, and of late years spent her holidays in exploring the more inaccessible parts of Central Europe. She leaves a widowed mother, whose sole companion she had been for a number of years.

## News and Views

## King's Birthday Honours

THE King's birthday honours list contains the names of the following scientific workers and others associated with scientific work — *Viscount* The Right Hon Lord Buckmaster, chairman of the Governing Body of the Imperial College of Science and Technology *Knights Bachelor* Dr H B Brackenbury, chairman of the Council of the British Medical Association, Mr R H Davis, governing director of Messrs Siebe Gorman and Co, Ltd, inventor of the Davis submarine escape apparatus and of a submersible decompression chamber for use in deep sea diving, Dr Robert L Mond, president of the Faraday Society and of the Egypt Exploration Society, Mr MacPheison Robertson, for services in connexion with the Antarctic Research Expedition, 1929–31, Prof W Wright Smith, regius professor of botany in the University of Edinburgh, and regius keeper of the Royal Botanic Garden, Edinburgh *CB* Dr C V Drysdale, director of scientific research, Admiralty *CSI* Brev-Col F P Mackie, director of the Pasteur Institute and Medical Research Institute, Shillong, Assam *CMG* Mr H E Hurst, director-general of Physical Department, Ministry of Public Works, Egypt, Mr F A Stockdale, agricultural adviser to the Secretary of State for the Colonies *CIE* Mr R D Richmond, chief conservator of forests, Madras *CBE* Mr A W Clapham, secretary of the Society of Antiquaries, Dr Eleanor Constance Lodge, until recently principal of Westfield College, University of London, Mr R J Reynolds, honorary adviser in radiology to the Ministry of Pensions, Prof R G Stapledon, professor of agricultural botany, University College of Wales, Aberystwyth, and director of the Welsh Plant Breeding Association *OBE* Mr W G Fairweather, director of surveys, Northern Rhodesia, Mr H E Flint, deputy conservator of forests, Burma, Mr A M Henshaw, a member of the Safety in Mines Research Board, Mr F T Morehead, deputy conservator of forests, Insein, Burma, Mr H B Owen, medical superintendent and principal, Medical School, Mulago, Uganda Protectorate, Mr G Shearing, principal scientific officer, Naval Signal School, Portsmouth, Dr H C Sinderon, dean of the Royal College of Medicine, and physician of the Royal Hospital, Ministry of the Interior, Iraq, Mr C W Scott, forest economist to the Government of Burma, Major D R Thomas, chemical examiner to the Government of the Punjab, Mr G W M Woods, Indian Forest Service, Burma *MBE* Mr D W D'Silva, extra assistant conservator of Forests, Burma, Mr O E C Judd, deputy director of surveys, Bihar and Orissa, Mr H Kavanagh, timber assistant, Forest Department, Burma, Mr A Marshall, superintendent, Bacteriological Laboratories Section, Wellcome Tropical Research Laboratories, Khartoum Mr E Muir, research worker in leprosy at the Calcutta School of Tropical Medicine and Hygiene, has been awarded a bar to his Kaiser-i-Hind medal

## Honour for Sir Aurel Stein

IT is announced that the Council of the Royal Asiatic Society has awarded the gold medal of the Society "in recognition of distinguished services in Oriental Research" to Sir Aurel Stein, the well-known traveller and archæologist. For more than thirty years Sir Aurel Stein has been engaged in travel and exploration in Central Asia, with the authority and under the direction of H M Indian Government. His investigations among the sand-buried cities of Eastern Turkestan and Western China, where he shares with Sven Hedin the honour of pioneer exploration, have recovered for archæological and historical science a vast treasure of literary and official records, as well as of objects which reveal the art and culture of the early peoples of the Tarim basin. The remarkable achievements of their art in two directions in particular are demonstrated in two special publications dealing with this material—"Ancient Figured Silks Excavated at Ruined Sites of Central Asia" (1920) and "Ancient Buddhist Paintings from the Caves of the Thousand Buddhas on the Westernmost Border of China" (1921). The results achieved in the journeys carried out by Sir Aurel Stein under the order of H M Indian Government have been described in a number of carefully prepared and scholarly publications, of which the best known are "Sand-buried Ruins of Khotan" (1907), "Explorations in Central Asia" (1906–8), "Ruins of Desert Cathay" (1912), and "Serindia" (1921), which for a travel book achieved the almost unique distinction of becoming a 'collector's book' saleable at a high premium within a short time of publication. In another field, "On Alexander's Track to the Indus" (1929) deals with exploration and topographical research in the lands of the Indian north-west frontier. Sir Aurel Stein received the honour of K C I E in 1912.

## Sir William Crookes (1832–1919)

ON June 17 occurs the centenary of the birth of Sir William Crookes, who was born in London in 1832 and died in Kensington on April 4, 1919, at the age of eighty-six. Save for a year or two, all his life was spent in London, and at his death he was buried in Brompton Cemetery. The son of a tailor, he was sent for a time to the Grammar School, Chippenham, but his scientific training began when at the age of sixteen he became a student under Prof A W Hofmann at the Royal College of Chemistry. For four years he was one of Hofmann's assistants. He then spent a year as meteorologist at the Radcliffe Observatory, Oxford, and another as lecturer in chemistry at the Training College, Chester. At twenty-four years of age he married and returned to London, which henceforth became his home. Few men of science have had a more active or distinguished career than Crookes. For sixty years he was recognised as a most skilful experimenter, and he was likewise known for his intellectual independence and his wide interests. He first became well known through his

discovery in 1861 of the element thallium, a specimen of which was exhibited at the Hyde Park Exhibition of 1862. His subsequent researches extended to many branches of chemistry and physics, and his work often resulted in important applications of science to the arts and manufactures.

WHILE Crookes will probably be remembered longest for his researches on spectroscopy, on radiation, on the discharge of electricity in high vacua, and on the rare earths, much of his earlier work related to problems in practical chemistry. In 1859 he founded the *Chemical News*, of which he was editor until 1906, and his books included works on beet sugar, dyeing, metallurgy, manures, and similar subjects. In 1887 he served as president of the Chemical Society. Of the Royal Society he was a fellow for fifty-six years, being admitted F.R.S. in 1863, serving as foreign secretary from 1908 until 1912, and finally being elected president for the two years 1913 and 1914. He had already served as president of both the Institution of Electrical Engineers and the British Association, and it was in his address to the latter in 1898 he made his notable references to the problem of the world's wheat supply. Among his many distinctions were those of a place in the Paris Academy of Sciences, the honour of knighthood conferred on him by Queen Victoria in 1897, and the Order of Merit. There are portraits of him at the Royal Society and the National Portrait Gallery, his biography has been written by Dr. Fournier d'Albe, and an appreciation of his work by Prof. P. Zeeman, with a portrait, appeared in *NATURE* of Nov. 7, 1907, in our series of "Scientific Worthies."

#### Jubilee of St. Gothard Tunnel

ON June 1 the jubilee of the official opening of the St. Gothard Tunnel was marked by the unveiling by Signor Motta, President of the Swiss Confederation, of a sculpture entitled "The Victims of Work." This is a bronze casting of a sculpture made fifty years ago by the artist, Signor Vincenzo Vela, who intended it to decorate the entrance to the tunnel. The St. Gothard was the second of the five great alpine tunnels to be constructed, and it is the second longest. The first constructed was the Mont Cenis tunnel, driven by the engineers Sommeiller and Grattoni and opened in 1871. It is just over 8 miles long. The St. Gothard tunnel, constructed by Louis Favre (1826-79), who died in the tunnel of apoplexy, was begun in 1872, and is more than 9 miles long. The Arlberg tunnel through the Austrian alps, built a year or two after the St. Gothard, is  $6\frac{1}{2}$  miles long, the Simplon tunnel, opened in 1906, is  $12\frac{1}{2}$  miles long, and the Lotschberg tunnel, completed in 1911, is  $8\frac{1}{2}$  miles long. The St. Gothard tunnel connects northern and central Switzerland with Canton Ticino. Its northern opening is at Goschenen and its southern at Airolo, its central point is 3786 ft. above sea-level. The railway line from Zurich to Chiasso at the Italian frontier, which passes through the St. Gothard, was electrified about ten years ago, and trains cover the distance of 151 miles in 4 hr. 35 min.

No 3267, Vol. 129]

#### Television Transmissions of the Derby

ON June 1 a television image of the Derby was shown at the Metropole Cinema, Westminster, to an overflowing audience. The television transmitter was situated on the racecourse adjacent to the winning post, and the audience at the Metropole were able to see the horses as they walked past the grand stand for the parade and again as they flashed past the winning post at the finish of the race. Vision was accompanied by a running commentary given by a commentator standing in the television caravan. The apparatus at the transmitter comprised a mirror drum revolving at 750 r.p.m. This revolving mirror drum casts a succession of images over three photo-electric cells, each of the mirrors of the drum being set at a slightly different angle from that of the preceding one, thus causing the image to be divided into a succession of strips. A drum with 30 mirrors was used, and the ratio of the picture for each photo-electric cell was 3 by 7, the picture received at the Metropole being constituted by three such pictures projected in three adjacent zones to form one composite image.

THE picture ratio was kept at 3 by 7 and the speed at  $12\frac{1}{2}$  so that the centre zone of the picture could be broadcast by the B.B.C., and this broadcast took place in the national programme simultaneously with the demonstration to the cinema audience. The receiver in the cinema comprised a mirror drum similar to that at the transmitter, three small arc lamps and three Kerr cells supplying the modulated light for the three zones. The image was projected on a translucent screen approximately 10 feet by 8 feet. During last week transmissions have been supplied from the Baird Studios in Long Acre on a single zone, and a number of representative people appeared before the television transmitter in Long Acre and addressed the audience at the Metropole from the television screen. Among those who appeared were Sir Ambrose Fleming, Sir Richard Gregory, and Sir Ian Hamilton.

#### World Production of Metals and Coal

THE speech recently delivered by Sir Robert Hadfield at the annual general meeting of Hadfield's, Ltd., gives some interesting statistics for the total production of gold and silver from 1493 to 1931, and of copper, iron, and coal from 1800 to 1931. The world's production of gold in these 438 years amounted to 32,500 long tons, valued at £5,100,000,000, for silver the corresponding figures are 397,000 tons and £2,900,000,000. For copper, iron, and coal the corresponding figures for the period 1800-1931 are 39,500,000, 2,895,000,000, and 52,000,000,000 tons and £2,200,000,000, £16,000,000,000, and £39,000,000,000. The comparative production is illustrated in a striking model prepared by Sir Robert Hadfield, which shows that the total production of gold in these periods would go in a cube of no more than 40 feet side, whereas silver would require a cube the side of which was 111 ft. long, copper 530 ft., iron 2360 ft., and coal 11,200 ft.

### The Gold Standard

Compared with that of other metals the production of gold is insignificant, and recent events which have demonstrated the defects in the gold standard and induced many nations to come off the gold standard have led many people to wonder whether gold is a suitable metal to be used as a standard at all. The diagrams and models prepared by Sir Robert Hadfield enable us to visualise more clearly the extent to which gold can now be merely a basis for currency. On the other hand, while the output of gold according to expert opinion shows a marked tendency to decrease, the increasing volume of the world's trade tends to augment the demand for gold as a basis for currency under our old systems of currency. In addition, the concentration of 75 per cent of the gold stocks of the world in the United States of America and France, where it is not used as the basis of so much money as in the countries from which it was withdrawn, has tended to accentuate the shortage. Without advocating a definite change or the adoption of bimetallism, Sir Robert suggested that the currency situation merited expert investigation and consideration by an authoritative international organisation such as the League of Nations. Certain reforms have in fact already been suggested by the League of Nations' Gold Delegation, and are outlined in a recent memorandum on "The Functioning of the Gold Standard", submitted by Dr Feliks Mlynarski, which equally with Sir Robert Hadfield's speech will repay study not only by economists but also by those who are endeavouring to arrive at an intelligent view of the world's financial and economic situation.

### Return of the *William Scoresby*

THE Royal Research Ship *William Scoresby* reached London on June 6 after a commission of nineteen months in the service of the "Discovery Committee". On her arrival at the East India Docks she was inspected by Mr E R Darnley, chairman of the committee, and by Vice-Admiral H P Douglas, who congratulated her personnel on the valuable scientific results which had been obtained. The work of the ship has been in the charge of Mr E R Gunther as chief scientific officer, with Commander T A Jolliffe, R N (ret'd), in executive command. After leaving England in November 1930, the *William Scoresby* was engaged for some months in oceanographic work on the whaling areas of the dependencies of the Falkland Islands, during which, with favourable ice conditions, observations were extended so far south as lat 70°. During the southern winter of 1931 she was occupied in a survey of the Humboldt current on the west coast of South America, taking fifteen lines of stations at right angles to the coast, at each of which observations were made on the plankton and on the physical characteristics of the water at different depths. The lines of stations cover an area extending from Cape Carranza to Santa Elena, a distance of about 2200 miles, and it is already clear that the results will provide much new information on the current and on the wealth of animal life that it contains. More recently the ship has been employed in a third and

final survey of the trawling grounds lying between the Falkland Islands and the American coast. The survey was carried out with great thoroughness, and is expected to yield adequate data on the commercial possibilities of the area.

### Mexican Earthquake of June 3

AN earthquake of unusual severity occurred early on June 3 in the west of Mexico. The towns most seriously damaged, as known at the time of writing, are Colima and Guadalajara, which lie between 270 and 290 miles to the west of Mexico City. At Colima seventeen persons were killed, and at Guadalajara and in the surrounding district more than thirty. In the whole area, the number of lives lost is estimated at more than four hundred. Manzanillo, about twenty-five miles west of Colima and on the sea coast, is believed to have suffered more severely than either of the above cities, but all communications with it have been interrupted. In Mexico City, three violent shocks were felt, though the damage there was slight. According to the Mexican Seismological Bureau, the epicentre was 400 miles from the capital, and thus, as it lay in the direction of Colima and Manzanillo, it must be submarine, as in so many other recent Mexican earthquakes, but somewhat farther to the west. As in other earthquakes of the same country, the area of damage was of great extent, suggesting that the depth of the focus was considerable.

### Challenge to Witches in West Africa

THE sequel to the challenge to witches issued by the Christian Council of the Missions of West Africa (see NATURE, March 26, p. 464) was described by the Bishop of Accra at the fifth festival of the Accra Diocesan Association, held at Westminster on May 31. He recalled that the Council, in its desire to show that a great deal of West African witchcraft is nothing but fraud, had offered the sum of £10 to any witch who, in the presence of a representative of the council, should perform one of their favourite tricks, such as eat a papaw from a distance, remove an article from a locked box, or change a person into a bird, beast, or fish. Up to the time he left Accra some weeks ago, the only reply to the challenge had come from a wizard, who was unable to come to Accra, but offered, if the Council would go to him, to kill a man at a distance of forty miles. The Bishop hoped the challenge would be taken up, though not exactly in that form. The witches of Africa, he said, form a great secret society which is a source of harm to the people. The Europeans are outside a wall drawn around the native, as it were, and know very little about what goes on within.

### Guthrie Lecture of the Physical Society

THE seventeenth Guthrie Lecture to the Physical Society will be delivered on June 17 at 5 P.M. at the Imperial College of Science and Technology, South Kensington, by Dr Max Planck, of Berlin, who will take as his subject "The Concept of Causality in Physics". Planck's greatest scientific achievements are the outcome of a study of thermodynamical principles and their multifarious applications. He was

thus led at the end of last century to the problems presented by full radiation, the last remaining problem of which, that of the energy distribution, he solved by formulating the quantum theory. The new feature in Planck's theory finds its expression in terms of the 'quantum of action', symbolised by the letter  $h$  (Planck's constant). This is a very small quantity, and the quantum theory consequently exhibits its special peculiarities only when applied to the small-scale phenomena for which it is needed. Applied to large-scale phenomena it coalesces, as it should do, with classical physical theory (in which we may include relativity). Planck's work has been creative in a higher sense than that of any of his contemporaries or predecessors, in that it has introduced, for the first time in the history of science, concepts that are really new.

#### Grasshopper Invasion in the United States

WE learn from Science Service, of Washington, D C (May 12), that a grasshopper invasion of exceptional severity is predicted to occur over the western United States. Field observations carried out over many years have shown that dry summers followed by relatively mild winters provide ideal conditions for these insects. The summer of 1930 was the driest on record, while that of 1931 was one of the hottest, as well as being a dry one. The past two winters have not been severe, and the consequence is that grasshoppers have become increasingly numerous in parts of the west. Last year, vast number of eggs were deposited in the ground, and now these eggs are hatching. The only possible control measure consists in the broadcasting of an arsenic-poisoned bran-mash bait, which the insects devour with avidity, and are killed thereby. The cost of its application over wide areas is large, and strong endeavours are being made to obtain funds from Congress that will enable the western farmer to apply this weapon in time to save his crops. Ample warning appears to have been given by entomologists, and others, with respect to what is described as the greatest grasshopper invasion of the past half-century, that is now threatening a large section of the country. It is obvious that only co-ordinated and very prompt action can alleviate the situation that is predicted to arise.

#### Celery Growing

IN view of the increase in consumption and production of celery in Great Britain, the Ministry of Agriculture has recently issued a new bulletin (No 47) on celery growing (London: H M Stationery Office 6d), in which the cultural methods used by the specialist growers and the results of scientific investigations obtained by the Midland Agricultural College are described. At one time the chief celery-growing district was the Isle of Axholme, but it is now produced to a considerable extent in Lancashire, the Fens of Cambridgeshire, and Huntingdonshire. A good celery soil must be deep, though easily worked, and contain a high percentage of organic matter. The water supply must be plentiful, but good drainage is essential. Besides a heavy application of farm-yard manure, a dressing of superphosphate is recom-

mended prior to planting, while a top dressing of sulphate of ammonia is commonly given in July. The plants are raised from seed in hotbeds, and after being bedded out in small plots for about two months, are transferred to the field about June, this final planting being a highly skilled operation. The time at which the celery is lifted depends on the variety and nature of the soil, but it may be ready as early as the end of August. The question of the best methods of grading and trimming for the market is receiving attention. The avoidance of disease is of the utmost importance in celery growing. If entirely clean seed is not procurable, it should be treated with some disinfectant, such as weak formalin, before being sown, and further, spraying of the plants both in the beds and in the fields should be regarded as a routine operation if a successful crop is to be obtained. For further particulars of such treatments, readers are referred to *Bulletin 25*, where celery diseases and their control are dealt with in detail.

#### Early Man in Java

DETAILS of the discovery of another new type of man in Java a few months ago have now been published, as is noted by Prof. Elliot Smith in a letter to the *Times* of June 3. The discovery was made by Mr C. Ter Haar, and the remains and circumstances of discovery are described by Mr F. F. Oppenorth, of the Geological Survey of Java, in the official publication of the Survey, issued at Batavia. In the course of the examination of the pliocene and pleistocene deposits of the Solo River valley, the greater part of a brain-case and two fragments of a second were found in a bone bed at Ngandong, more than twenty miles from Trinil, where Dr Dubois found the remains of *Pithecanthropus erectus* in 1891. The fossil bones of fauna associated with the Ngandong find point to a mid-pleistocene age. The brain-case is described as of a more advanced type than *Pithecanthropus*, and to resemble more nearly Neanderthal man and the Rhodesian skull. It is, however, definitely more primitive than either and probably more ancient. The name suggested for this new species of the human family is *Homo soloensis*.

#### Criminal Anthropology

CRIMINAL anthropology, which for some time has suffered an eclipse owing to ill-judged claims which had little or no foundation on sound observation, is once more attracting the attention of investigators. In *Scientia* for May, Prof. A. Mendes-Corrêa recapitulates views which he has put forward from time to time on the contribution which a re-orientated anthropological method can make to the study of criminals and to practical measures in dealing with delinquents. The method advocated by the author is based on a study of the individual, whether normal or abnormal, in reference to his individual psychic and moral make-up and his biological and sociological conditions. Measurements, somatic characters, mental tests, and other methods employed in dealing with delinquents and defectives are regarded as auxiliary rather than as primary methods of investigation in criminological research. Prof. Mendes-Corrêa regards

the new criminal anthropology as a development of the Lombrosian methods which has shed the defects of that school. On the other hand, a preliminary study of the American criminal by Prof E A Hooton, as reported by Science Service of Washington, more nearly approaches the methods of Lombroso, in that it endeavours to relate delinquency and physical type. Prof Hooton's conclusions are, however, based on a large number of observations extending over a considerable period. He is of the opinion that his material justifies the conclusion that criminals in the totality of their physical characters differ from civilians of the same ethnic type. Certain variations of physical type tend to be associated disproportionately with certain types of crime.

#### Regenerative Braking on Trains

THE paper on tramway regeneration by G H Fletcher which was read to the Municipal Tramways and Transport Association, the last instalment of a reprint of which appears in the March issue of the *Metropolitan-Vickers Gazette*, is of great interest to tramway engineers. In regenerative braking, when the electric tram or train is going downhill, its own momentum drives the motors of the car as dynamos, thus absorbing energy and acting like a mechanical brake. It also converts the gravitational potential energy into electrical energy which is restored to the line, helping the power station, and thus leading to economical working. The advantages of the regenerative system are the reduced energy consumption and the reduced wear of brake shoes and wheel tyres, and the consequent lowering of maintenance costs. The disadvantages are that the motors are larger and more costly. There are many examples of remunerative regenerative braking abroad in mountain railways and on lines where the gradients are heavy. The Metropolitan-Vickers Company has equipped two sample tramcars on the Manchester and Glasgow corporation systems respectively with regenerative control. The equipment enables the kinetic energy of the train to be recovered and returned to the line instead of being dissipated in the brakes. The Manchester car has now been on service for some months and the Glasgow car has run several special trials. Both have worked very satisfactorily, effecting appreciable savings in power consumption. A specially equipped car was paired with a standard car and the two worked together for definite periods on a number of routes. The results show that the regenerative tram on an 8.5 miles per hour service on a comparatively flat route took twenty-seven per cent less power than the standard tram.

#### Annual Symposium on Colloid Chemistry

THE tenth annual Symposium on Colloid Chemistry will be held in Ottawa, Canada, on June 16-18. About two hundred workers in this field of science are expected to attend the meeting, and Mr Emil Hatschek, lecturer on colloids at the Sir John Cass Technical Institute in London, will be the principal guest and speaker. He will read a technical

paper and will also give an evening lecture; the sessions will be held in the newly constructed National Research Laboratories. Papers will be presented on the colloid chemical aspects of such diverse subjects as the constitution of rubber, by Thomas Midgley, of Columbus, Ohio, diphtheria toxins and antitoxins, by P J Moloney, of the Connaught Laboratories, Toronto, asphalts by Charles Mack, of the Imperial Oil Company at Sarnia, studies in cellulose, by O Maass, of McGill University, Montreal, colloidal arsenic by E F Burton, of Toronto University, gelatin, by S E Sheppard, of the Eastman Kodak Company, Rochester, N Y, resins, by C H Winning, of the University of Wisconsin, Madison, cane wax in raw and refined sugar, by C F Bardorf, of the St Lawrence Sugar Refineries, Montreal.

#### Committee on Slaughter-house Methods and Equipment

THE British Science Guild has appointed a Committee on Slaughter-house Methods and Equipment, "To verify and tabulate information relating to methods of, and equipment for, the slaughtering of animals for food, with especial reference to sanitary, dietetic, and humane requirements, to investigate new methods and equipment, to convey information on the subject to local authorities and other bodies and persons." The Committee consists of Lieut-Col Sir Arnold Wilson (chairman), Capt C W Hume (vice-chairman), Mr John McMath (honorary secretary), and the following members appointed on the recommendation of the bodies indicated: Mr John Fearn (Institution of Mechanical Engineers), Dr Charles Porter (Society of Medical Officers of Health), Sir James Douglas and Mr R Stephen Ayling (Model Abattoir Society), Prof F T G Hobday and Lieut-Col T Dunlop Young (Royal College of Veterinary Surgeons), Mr J R Hayhurst (Royal Sanitary Institute), Lieut-Col T C R Moore and Mr R O P Paddison (Royal Society for the Prevention of Cruelty to Animals). The Medical Research Council has also been invited to recommend a member.

#### Birds in Inner London

A SHORT article in the May number of *British Birds* (p 355) reveals unexpected variety of bird life in the heart of a great city. The presence of gulls has become commonplace, and it is not surprising that birds on migration should be heard passing overhead, like the curlews mentioned. But the settling of exhausted landrails and a woodcock, the appearance of young cuckoos in several gardens, of wheatears in Regent's Park, of a black-necked grebe in Kensington Gardens, a cormorant on the cross of St Paul's Cathedral, and a pair of kestrels nesting in the belfry of St Paul's School, Hammersmith Road—these are things which must have surprised and delighted the fortunate observers.

#### Bureau of Contraceptive Advice

A STATISTICAL analysis by Prof Raymond Pearl on the year's operations of the Bureau for Contraceptive Advice, Baltimore, has been issued. During this, its

fourth year, 233 new cases attended the Bureau. All were married women, their average age was 30.44 years, and the average duration of marriage was 10.9 years—figures which refute some of the objections urged against contraception. Prof. Pearl considers that the Bureau has been in operation too short a time to make any definite report on the effectiveness of the advice given as to the technique of contraception.

#### Announcements

PROF. JACQUES HADAMARD (Paris), Prof. Graham Lusk (New York), Prof. Walther Nernst (Berlin), and Prof. Theobald Smith (Princeton) have been elected foreign members of the Royal Society.

M. LE DUC DE BROGLIE, who contributed to *NATURE* of May 7 the survey of Lord Rutherford's work which appeared in our series of "Scientific Worthies", has been elected an honorary member of the Cambridge Philosophical Society.

THE Council of the Chemical Society has awarded the Longstaff Medal for 1933 jointly to Prof. W. N. Haworth, of the University of Birmingham, and Sir James Irvine, of the University of St. Andrews, for their outstanding work on the chemistry of the sugars.

THE Joint Committee of the Royal Society of Edinburgh, the Royal Physical Society, and the Royal Scottish Geographical Society has awarded the Bruce Prize for the period 1930-32 to Mr. Herbert G. Watkins, for important contributions to the topography of Spitsbergen, Labrador, and East Greenland and investigation of the ice cap of Greenland. Mr. Watkins was leader of the Cambridge Expedition to Edge Island, Spitsbergen, 1927, leader of the Cambridge Expedition to Labrador, 1928-29, leader of the British Air Route Expedition to East Greenland, 1930-31, and will be leader of the projected expedition to Coats Land, 1932.

PROF. P. DEBYE, of Leipzig, has accepted the invitation of the Council of the Chemical Society to deliver the fifteenth Faraday Lecture on March 29, 1933.

SIR FREDERICK GOWLAND HOPKINS will open a discussion on "Recent Advances in the Study of Enzymes and their Action" to be held at the Royal Society on June 16. Other speakers will include Prof. R. Willstätter, of Munich, Prof. Waldschmidt-Leitz, of Prague, Dr. Richard Kuhn, of Heidelberg, Prof. A. Harden, Prof. J. B. S. Haldane, Dr. D. Keilm, and Dr. J. H. Quastel.

THE sixth Stephen Paget Memorial Lecture of the Research Defence Society will be delivered by Sir Arthur Keith at the annual general meeting of the Society to be held at the London School of Hygiene and Tropical Medicine on June 15 at 3 p.m. Sir Arthur will speak on "Some Aspects of the Modern Conflict between Reason and Sentiment."

MESSRS. Charles Baker, 244 High Holborn, London, W.C.1, have prepared a new issue (No. 101) of their classified list of second-hand scientific apparatus. Section I, dealing with microscopes and their accessories, is very full and covers a wide range of makes

and equipment. There is also an extensive section on surveying instruments, and others on astronomical and physical apparatus generally. Surveying instruments can be hired, and lantern exhibitions are arranged.

"La Maison de la Chimie" which is being erected in Paris will constitute an important centre of chemical activities. Apart from several meeting halls, the largest of which will accommodate a thousand people, it will contain an extensive library with special means of documentation, including films and discs, and the latest technical improvements. The building of this centre has been made possible by an international subscription on the occasion of the centenary of Marcelin Berthelot, and the gift by the French Government of the old palace de la Rochefoucauld d'Estissac, which is being reconstructed and extended to make it suitable for its new function.

WE have received from Messrs. British Drug Houses, Ltd., Graham Street, London, N.1, a copy of "B.D.H. Reagents for Delicate Analysis and Spot Tests", which contains descriptions of several new reagents for the detection of substances with minute amounts of material. Many of the reagents are specific, so that it is now frequently possible to avoid group separations. In each case references to the original literature are given, so that the information is useful as an addition to analytical chemistry. The price of the book, which is well bound, is 2s. 6d.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A woman lecturer in geography at Bingley Training College—The Education Officer, County Hall, Wakefield (June 15). A radium officer for a National Radium Regional Centre at Southampton—The Secretary, Royal South Hants and Southampton Hospital, Southampton (June 18). A head of the commerce department of the Gamble Institute, St. Helens—The Secretary for Education, Education Office, St. Helens (June 20). A laboratory assistant at the Joint Counties Mental Hospital, Carmarthen—The Clerk to the Visitors, 34 Quay Street, Carmarthen (June 20). An assistant lecturer in mathematics in the University of Sheffield—The Registrar, University, Sheffield (June 21). An assistant lecturer in geology in the University of Birmingham—The Secretary, University, Birmingham (June 23). An assistant lecturer in metallurgy and assaying at the Manchester Municipal College of Technology—The Registrar, College of Technology, Manchester (June 30). A lecturer in mathematics in the Manchester Municipal College of Technology—The Registrar, College of Technology, Manchester (July 2). A resident lecturer for biology and some mathematics at Stockwell Training College for Women—The Principal, Training College for Women, Stockwell, S.W.9. An assistant master, honours graduate in engineering, for the Day Technical and Commercial School, Westcliff-on-Sea—The Headmaster, Day Technical and Commercial School, Fairfax Drive, Westcliff-on-Sea.

ERRATUM.—*NATURE*, June 4, page 819, col. 2, lines 20-21, for *Pieris rapae* read *Pieris napi*.

## Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

### Photochemistry of Vitamins A, B, C, D

FROM their letter in NATURE<sup>1</sup> and various reports in the daily Press, it would appear that the work of Drs F P Bowden and C P Snow provides a new and powerful technique offering the prospect of an immediate extension of knowledge concerning vitamins. In scrutinising the evidence disclosed in favour of this claim, we find ourselves in difficulties. In the first place, the technique (the study of spectral absorption curves, and irradiation with light of selected wave-lengths) is familiar and has already been applied in vitamin studies, while in the second place, the idea of one experimental method as a key to several vitamins seems to underestimate the differences between organic compounds of widely varying constitution sharing only a capacity to induce unusual (but quite diverse) physiological responses. Drs Bowden and Snow evoke two possibilities

(1) The association of an absorption band with a vitamin on the basis of the disappearance of both activity and absorption as a result of irradiation with light of defined wave-lengths. Useful results on these lines have already been described for vitamin A in 1928.<sup>2</sup>

(2) That "When applied to a suitable pre-vitamin, monochromatic irradiation with light of the correct wave-length produces maximum yields of the vitamin." Apart from the ambiguous term "maximum yields", this statement is baldly true of existing knowledge concerning the ergosterol  $\rightarrow$  vitamin D transformation. The claim to have extended the idea of a photochemical precursor substance, by experiment, to other vitamins, is a recent departure first put forward by Rygh<sup>3</sup> in connexion with narcotine and vitamin C, and now again advanced by the authors in connexion with carotene and vitamin A. The work of Rygh has already been subjected to criticism,<sup>4</sup> and it is now necessary to consider the contribution of Drs Bowden and Snow. In the case of vitamin D, an association with photochemistry is of long standing (light therapy, especially in relation to rickets), but with vitamin A the association is exclusively with a metabolic rather than a photochemical pre-vitamin. Having observed the presence in  $\beta$ -carotene of a band at 270 m $\mu$  (this band has previously been recorded),<sup>5</sup> the authors subjected a solution of  $\beta$ -carotene in cyclohexane to monochromatic irradiation (Hg 265 m $\mu$ , 253.7 m $\mu$ ) in an atmosphere of nitrogen. After a few hours a strong band appeared near 328 m $\mu$  and the resultant product was found to give a blue colour with antimony trichloride. From these results, pending biological experiments, a photochemical transformation of carotene into vitamin A is claimed.

Now, whereas the vitamin A of liver fat is a practically colourless alcohol (most probably C<sub>20</sub>H<sub>30</sub>O  $\overline{\text{F}}$ )<sup>6</sup> exhibiting near 328 m $\mu$  a band of defined intensity ( $E_{1\text{ cm}}^{1\text{ per cent}}$  1350) and giving a blue colour with antimony trichloride sharply differentiated ( $\lambda_{\text{max}}$  617 m $\mu$ ) from the blue colour given by carotene ( $\lambda_{\text{max}}$  585-590 m $\mu$ ),<sup>7</sup> the experiment of Bowden and Snow, properly executed, can only yield hydrocarbons. From the published spectrograms their product is obviously

coloured and in all probability contains unchanged carotene, so that the relevance of the promised biological assay does not emerge, since it has been fully established<sup>8</sup> that carotene is converted *in vivo* into vitamin A.

The one piece of concrete evidence is the recognition of a new maximum near 328 m $\mu$ . In this instance the authors are using the band as a criterion for a complex molecule, but elsewhere in their communication they refer to the diagnosis of absorbing groups. At the best, they have evidence of a product possessing a molecular grouping similar to that present in vitamin A, but they omit to deal with the obvious and more probable explanation, namely, a molecular rearrangement. Actually, we have observed here that *iso*-carotene,<sup>9</sup> which is a coloured substance readily obtained from carotene in various ways, also possesses a sharp band near 320 m $\mu$ . The destruction of vitamin A by radiation within the 328 m $\mu$  band has already been fully demonstrated.<sup>9</sup>

*Vitamin B.*—The fact that a crystalline specimen of this vitamin exhibits absorption maxima at 260, 240, and 210 m $\mu$  is an interesting qualitative observation, the value of which for the diagnosis of structure remains to be demonstrated. For purposes of assay, the observation only becomes useful if it can be shown that the materials normally accompanying the vitamin are themselves much more transparent in the region 200-270 m $\mu$ . That irradiation (Hg 253.7 m $\mu$ ) destroys the vitamin and effects the disappearance of the 260 m $\mu$  band is in no sense surprising. If the material were pure, then obviously the other bands must equally be properties of the vitamin, and hence the claim that the physiological activity arises in some special sense from the part of the molecule giving rise to the 260 m $\mu$  band, far from being "fully established", is unjustified. Until the structure of the organic molecule is at least broadly established, this kind of interpretation of spectral absorption data is both uninformative and premature.

*Vitamin C.*—Drs Bowden and Snow state that when they are able to record the absorption spectrum of pure vitamin C, they will be able to test its identity with either irradiated narcotine or hexuronic acid. This is so true as to be obvious, but the necessity for monochromatic irradiation does not emerge.

*Vitamin D.*—Here Drs Bowden and Snow appear merely to have confirmed earlier observations, except as regards the sentence "the spectroscopic evidence is, however, already sufficient to indicate that the conversion of ergosterol into calciferol depends on the migration of a double bond to a position in which its influence on the other double bonds is greatly enhanced" (our italics). We would inquire what the authors intend to convey by the italicised phrase. So far as the known absorption spectra of calciferol and ergosterol are concerned, the statement conveys no meaning whatever. No indication is given of any other criteria of 'enhanced influence', neither is it clear what is meant by the *elimination* of an absorbing group from a complex organic molecule by irradiation with light of related frequency. Before such considerations can be of much avail, it is essential to know exactly the nature of the absorbing group—and in most complex organic compounds, the present position of the interpretation of absorption spectra does not make this possible. In this connexion neither the origin of the ergosterol bands nor the calciferol band is yet understood. The possibility of a rearrangement of the double bonds of ergosterol has already been fully studied by Windaus<sup>10</sup> by strictly chemical methods.

In the case of vitamin A, the effective entity is possibly a system of four conjugated double bonds. We can understand a photochemical process breaking

up this system, but eliminating the group with "ease and certainty" has no precise meaning

### Resistance of the Eggs of Collembola to Drought Conditions

THE activity and abundance of Collembola are closely associated with the moisture of their environment. The species *Sminthurus viridis* (L.) Lubbock occurs in large numbers in certain areas of South Australia during the rainy season (May to October). The numbers rapidly decrease when the dry season sets in and, normally, the insect does not occur again until about the following May.

Certain of the eggs remain dormant in the soil during the dry season. This condition is not due to a definite rhythmical diapause, but is enforced owing to the lack of moisture in the surface soil during this

FIG 1

season. The eggs can be induced to hatch with suitable moisture and temperature.

During experimental work with this species, it was found that with egg batches, exposed to dry conditions for varying periods and then remoistened, the eggs commenced to hatch in a comparatively short time, showing that some development had taken place prior to being remoistened.

The stage of development attained by the eggs prior to the onset of dry conditions is an important factor affecting the number which survive a temporary drought period. 100 egg batches of *S. viridis*, estimated at 4500 eggs, were arranged in eight series (Series 7 to 0). The number of batches in each series was 18, 13, 14, 13, 14, 9, 8, 11. The batches were laid on moist soil contained in 2½-in. flower pots, the conditions being uniform. There were six pots in

each series, and the batches were retained, as laid, *in situ* on the soil, throughout the experiment.

With Series 7, the pots were placed in an incubator at 24° C for 7 days from the date of being laid, the soil being kept suitably moist. With Series 6, the pots were 6 days in the incubator, and so on, with the remaining series to Series 0 with no days in the incubator. All the pots were then transferred to a heated glass-house on the same day (Aug. 15) and the soil allowed to dry out for 17 days. (Mean daily max temp 30° C, min temp 12° C. Mean daily relative humidity 56 per cent.) By Aug. 17 the moisture content of the surface soil, based on the moist soil, was 2.5 per cent. On Sept. 1, the soil in all the pots was remoistened and the daily hatching from each series was recorded. (During the period, Sept. 1–16, the mean daily max temp was 28° C, and mean min temp 11° C.)

A total of 2144 eggs hatched. The mean number of eggs per batch which hatched in each series is shown in Fig. 1, A, and the daily total of eggs which hatched from all the series is shown in Fig. 1, B. (In Series 7, 93 eggs hatched during Aug. 17–20. In Series 6, 86 eggs hatched during Aug. 18–20. These are not included.) I have discussed the normal incubation period elsewhere.<sup>1</sup>

The relative resistance of the egg at different stages appears to be associated with the changes occurring during development. In the advanced stages of the embryo, the egg swells and the chorion splits at the equator. Two polar caps are thus formed which gradually separate, revealing the embryo surrounded by a transparent membranous envelope.

Ripper<sup>2</sup> has described changes in the egg of *Hypogastrura* in this respect, which differ in detail from that of *S. viridis*.

### Inheritance of Milking Capacity

IN replying to Mr. Buchanan Smith's remarks<sup>1</sup> concerning my discussion<sup>2</sup> of Mr. Madsen's letter,<sup>3</sup> I shall deal with them in the order set out by him.

(1) I suggested that the small correlation to the paternal granddam might be explained by the selection of the sires of bulls studied as prepotent on the basis of the progeny test (rather than on their dams' records), a form of reasoning used by Mr. Buchanan Smith for another purpose<sup>4</sup> in discussing a low correlation of daughters' yields to their paternal granddams' yields when he states "this may probably be explained by the fact that up till quite recently in the Ayrshire breed the bull was selected not on the performance of his dam so much as on the show-yard record of his sire." In each case the principle is obviously the same—the bull being selected with little reference to his dam's record. Mr. Buchanan Smith's statement that "when the full paper is published Mr. Madsen will show that the majority of sires involved have not been selected on genotype but on appearance plus pedigree" is difficult to reconcile with Mr. Madsen's own statement about "breeders who for the past 15 years have, through an intelligent appreciation of the progeny test, paid almost exclusive attention to the male line."

(2) Rather than to the contrary we find ourselves in agreement on the second point, I stated that a cow's record is insufficient in foretelling the production

of her progeny because it is the expression of a phenotype and Mr Buchanan Smith allows that rarely is the cow's genotype capable of assessment because of the small numbers of her progeny. This is a state of affairs in no way improved upon by any increase in the number of daughter-dam pairs, and as in discerning inheritance it is essential to distinguish transmitting ability from actual production, it is difficult to see why two small correlations to phenotypes far removed can be expected to reveal anything. Actually the correlations amongst genotypes in Mr Madsen's data should more reasonably be expected to yield a clue, as the X-chromosome which the bulls receive comes as often from the maternal grandsire as from the maternal granddam, though never from the paternal grandsire. Mr Madsen finds that to the latter parent  $r = 0.202$ , while to the maternal grandsire  $r = 0.194$ , which would indicate that the presence or absence of the X-chromosome makes no difference.

The method of direct correlation employed leaves much to be desired. To a daughter's inheritance the sire and dam each contribute and yet in the daughter-dam correlations the sire's part is completely left out of account. This omission is not made good by an increase in the number of daughter-dam pairs studied.

(3) and (4) That the suggestion of inaccuracy in the calculation of the odds as one in ten is unfortunate is shown by Dr J Wishart in a letter contributed below.

I agree with Mr Buchanan Smith that Mr Madsen's investigation is particularly exhaustive and it is the very thoroughness with which he has prosecuted it which makes the likelihood of significant sex-linkage even more uncertain.

<sup>4</sup> Smith, A. D. Buchanan, and Robison, O. J., "The Inheritance of Milk Yield." Conference Papers, Internat. Dairy Cong., Copenhagen, 1st section, pp. 127-140, 1931.

THE standard errors of the correlation coefficients 0.026 from 721 pairs and 0.112 from 715 pairs are almost exactly equal, at 0.037. Thus the difference 0.086 is 1.64 times its standard error, and treating this as a normal deviate it appears that a difference of this size, or greater, would occur in random samples from equally correlated populations just once in ten times on the average. Mr Edwards used the more exact  $z$ -transformation of R. A. Fisher, but the small size of the correlations and the large numbers on which they are based, lead to exactly the same result by both methods. The observed coefficients are thus compatible with the hypothesis that the correlations with paternal and maternal granddam are equal. The best value for the joint correlation afforded by the data is 0.07, so that the relationship at best is very slight.

#### Light and Sexual Periodicity

IN the North Greenland (Peary) Expedition, evidence of sexual periodicity in the Eskimos was observed by Cook.<sup>1</sup> Thus, with the onset of the sunless winter, sexual desire fails and menstruation during the long period of darkness is absent. But with the dawn of spring a phase of sexual excitement or pro-oestrus ensues, menstruation returns, and the majority

of the children are born nine months after the return of the 'sun'. The girls marry at fourteen or fifteen years of age, but the menstrual flow does not begin until they are nineteen or twenty years old. Children are 'suckled' for four to six years, and on the average one child is born every four years. Stieve and others, too, have noted that in the long polar night Eskimo women neither menstruate nor conceive. If this hiatus in the sexual cycle be due to absence of light, it must be of 'sunlight', for moonlight is present in the polar night. Light and heat rays seem essential for maintenance of the sexual cycle.

This annual recurrence of a 'menopause' suggests a species of 'hibernation' localised to the hypophysio-gonadal system, and that it should be so restricted and not generalised is presumably due to the fact that they—unlike warm-blooded hibernants—have no 'fat gland' to draw upon during the long winter sleep. Hence the need of fat consumption, and body temperature stabilisation forbids such marked slowing down of tissue metabolism, pulse, and respiration—with consequent induction of sleep, oliguria, and poikilothermia—as occurs in true hibernants which pass the winter in a state of retarded animation.

This assumption of localised hibernation of the hypophysio-gonadal system recalls the many similarities obtaining between generalised hibernation and pituitary (anterior hypophysis) dysfunction. In hyper-pituitarism (acromegaly) sexual desire is increased, but in hypo-pituitarism abolished—males become impotent, and in females menstruation ceases. This correlated variation of pituitary (hypophysial) with gonadal functional activity indicates that the sexual cycle is controlled by the hypophysis and any interruption in sexual rhythm—apart from local causes—referable thereto. Hence, may not the recurring seasonal loss of sexual desire, with impotence in males and absence of menstruation in females, be due to seasonal suppression of the functional activity of the hypophysis (hypo-pituitarism) with its correlated cessation of gonadal activity—the same referable to lack of the stimulus 'sunlight'?

Alike in Eskimos and hibernants, for example, bear and sloth, the 'awakening' in spring—almost certainly due to resumption of hypophysial activity—signals the onset of the 'mating' or 'rutting' season. Further resemblances between hibernation and hypo-pituitarism are that in both states the basal metabolic rate and body temperature are lowered. Again, in both sexes in hypo-pituitarism 'adiposity' ensues, which possibly acts vicariously as a substitute for the 'fat gland' of hibernants. With these changes, too, are associated lethargy, slow pulse, and a moderate degree of somnolence. The parallel, then, between states of hibernation and hypo-pituitarism is suggestively close—the differences being quantitative rather than qualitative.

It has been suggested that the sexual periodicity in Eskimos is a racial peculiarity. But Cook—in alluding to the suppression of sexual desire and menstruation with "great muscular debility" in Eskimos—observes, "Our own party suffered in the same way." Their participation would seem to rule out any question of its being a racial peculiarity, indicating rather that all persons, when living in the arctic zone, react in like fashion to long-continued absence of 'sunlight'. As to the pathway of light transmission, that of vision first presents itself, and possibly light mediated through the hypophysis in this way influences the sex organs.

<sup>1</sup> F. Cook, *New York Journal of Gynecology and Obstetrics*, 1894.

Chromatid Segregation in Tetraploid *Rubus*

IN *Rubus rusticanus* an unprickled variety *inermis* occurs. The character behaves as a recessive in reciprocal crosses with the normal type. In 1927,<sup>1</sup> we showed how this character was inherited in tetraploid forms. A tetraploid seedling 'RT4' was raised from the cross *R. rusticanus inermis* ♀ ( $n=7$ ) by the tetraploid prickled species *R. thyrsiger* ♂ ( $n=14$ ), the female parent had given an unreduced egg with 14 chromosomes, which was fertilised by normal pollen of *R. thyrsiger*, also with 14 chromosomes. The constitution of RT4 in regard to the *inermis* character was, therefore, *AAaa*. With random segregation amongst four chromosomes (considered by Muller in 1915) it should have given a 35:1 ratio of prickled to unprickled. With regular segregation of *A* from *a* (allosyndesis) it should have given a 15:1 ratio. The proportion found was intermediate (471:19) and we considered therefore that randomness was modified in the direction of allosyndesis—an improbable but, as it then seemed, an inevitable explanation.

Haldane<sup>2</sup> has applied the principle of chromatid segregation to polyploids. This principle was first demonstrated in polyploid *Drosophila* and agrees with the simplified chiasmotype hypothesis of crossing-over. The ratios expected with random chromatid segregation in a tetraploid of the constitution *AAaa* are 20:78:1 (187:9) instead of 35:1, and in the backcross to *aaaa* 3:67:1 (11:3) instead of 5:1. The following table shows the comparison of new results obtained in the last five years with the two alternative expectations of random segregation of chromosomes and chromatids. (The possibility of allosyndesis need not now be considered.) The results agree closely with the chromatid expectation and differ significantly from the simple chromosome expectation.

|                                                 | Prickles     | No Prickles |
|-------------------------------------------------|--------------|-------------|
| <b>Selfed (<i>AAaa</i> × <i>AAaa</i>)</b>       |              |             |
| Observed (872 plants)                           | 835          | 37          |
| Chromatid expectation                           | 832.0 ± 6.2* | 40 ± 6.2    |
| Chromosome expectation                          | 847.8 ± 4.9  | 24.2 ± 4.9  |
| <b>Back-crossed (<i>AAaa</i> × <i>aaaa</i>)</b> |              |             |
| Observed (43 plants)                            | 33           | 10          |
| Chromatid expectation                           | 33.8 ± 2.7   | 9.2 ± 2.7   |
| Chromosome expectation                          | 35.8 ± 2.4   | 7.2 ± 2.4   |

\* Standard error,  $\sigma = \sqrt{p(1-p)/n}$

Blakeslee and his collaborators<sup>3</sup> have found recessives in the progeny of *AAAA* plants of tetraploid *Datura*, and *AAaa* plants also show ratios that may be accounted for by chromatid segregation. These are the only sharp deviations from the simple chromosome segregation yet observed in autotetraploids. The explanation is clear. Chromatids from the same parental chromosome have been shown to segregate together at the spindle attachment, both where chromatid segregation has been shown genetically<sup>4</sup> and where crossing-over has been proved cytologically.<sup>5</sup> Random chromatid segregation will therefore only be expected with factors having 50 per cent of observed crossing-over between them and the spindle attachment, a value which under most conditions is only approached asymptotically.

Observations of inheritance in tetraploids therefore confirm expectation based on general cytological and genetical observation, and particularly agree with the chiasmotype hypothesis of crossing-over.

## Resonance Spectrum of Hydrogen

It was reported in a previous communication<sup>1</sup> that, in the course of experiments by Dr J. S. Badami and me on the spectrum of arsenic by the Paschen hollow cathode discharge in helium, the Lyman series of hydrogen was obtained with remarkable strength, the important feature of the series being the curious intensity anomaly exhibited by the members. Instead of the intensity gradually falling off, a sudden enhancement was observed in that of the 10th and the 11th members ( $\nu 108,771$  and  $108,916$ ). Experiments under varying conditions indicated definitely that this intensity anomaly occurs only in the presence of arsenic. The suggestion was made that the energy of excitation of this resonance spectrum is to be sought for in a transfer, by collisions of the second kind, from the excited arsenic atoms. Since sending this report, values of the characteristic energy levels of the neutral and ionised atom of arsenic<sup>2</sup> have become available, and a consideration of these has confirmed the above explanation.

The reaction may be represented by the equation

where  $\text{As}^{+'}$  represents an arsenic ion in an excited metastable state. The existence of such states, formed by collisions of the second kind with excited rare gas atoms or ions, in the source employed, can be easily supposed from the experiments of various investigators on this method of discharge. The excitation energy of the enhanced 11th member of the hydrogen series is 13.44 volts, and the energy corresponding to a transition of the excited arsenic ion in the metastable state  $4p\ ^1S_0$  to the normal state  $4p\ ^4S_2$  of the neutral atom (that is,  $\text{As}^{+'} \rightarrow \text{As}$ ) is found equal to the above value within the limits of error involved in the estimate of the first ionisation potential of arsenic.

The phenomenon appears to be analogous to the observations made by Beutler and Josephy,<sup>3</sup> where a mixture of the vapours of sodium and mercury and a foreign gas was excited by mercury radiation  $\lambda 2537$ , and the lines  $2P - 5S$  and  $2P - 7S$  of sodium appeared with great intensity, the excitation energy of these lines corresponding closely to the energy of the excited states  $2\ ^3P_1$  and  $2\ ^3P_0$  of mercury. It is to be noticed that a close 'resonance' between the two colliding partners is of importance for this transfer of energy.

If the above interpretation of the phenomenon is accepted, we meet here with a type of collision which, so far as I am aware, has not hitherto been observed. We have evidence<sup>4</sup> of a simultaneous ionisation and excitation by collisions of the second kind with excited atoms, in which the reaction can be represented by the equation  $A + B' \rightarrow A^{+'} + B$ . The present phenomenon represents then a type of impact in which, clearly, the reverse process is involved.

A full report of the experiments will be published shortly.

## Photochemical Dissociation of Carbonyl Sulphide

WE have recently determined the ultra-violet absorption spectrum of carefully purified carbonyl sulphide, using a quartz spectrograph and a hydrogen discharge tube as a source of light. The spectrum shows a continuous absorption starting from a sharp limit at  $\lambda = 2550 \pm 20$  Å and extending far towards the ultra-

violet This spectrum is interpreted as corresponding to the dissociation of the COS molecule, which was also indicated by the deposit of sulphur on the walls of the absorption tube The products of dissociation may be CO and S, or CS and O The energies of these processes as calculated from thermochemical data are

The determined photochemical dissociation energy is 4.84 volts or  $111 \pm 1$  kcal and hence the dissociation must proceed according to (1) The difference between the observed and calculated dissociation energy is 35 kcal and corresponds to the excitation energy of the sulphur atom, since the first excitation potential of the carbon monoxide molecule, as obtained from band spectra analysis, is 5.9 volts above the ground-level The energy of 1.5 volts (35 kcal) corresponds to the difference in energy between the  $3p$  ground-level and the  $1d$  metastable state, as the lowest possible excitation energy of the sulphur atom The position of the latter term has not yet been established directly Christy and Naudé<sup>1</sup> have recently suggested 1.6 volts from a study of the predissociation spectrum of the sulphur molecule This is in excellent agreement with the above value

#### Rotation of Molecules in Crystals

AN investigation on the relation between the crystal structure and optical properties of organic crystals has revealed further cases of 'rotating' and 'fixed' molecule forms in aliphatic compounds A hexagonal rotating form has been observed between  $16^\circ$  and  $24^\circ \text{C}$  in dodecyl alcohol  $\text{C}_{12}\text{H}_{25}\text{OH}$  The distance between chains is 4.76 Å, corresponding to the 4.85 Å found by A. Muller<sup>1</sup> for paraffins The low temperature form, however, differs by being monoclinic with inclined chains corresponding to the high temperature form of the monobasic acids The transitions between these forms could be followed for single crystals in the polarising microscope

A non-rotating form of alkyl-ammoniohalide has been found for  $\text{C}_{18}\text{H}_{37}\text{NH}_3\text{Cl}$  It is orthorhombic with a base  $5.2 \text{ Å} \times 5.15 \text{ Å}$  as against  $5.02 \text{ Å}$  for the tetragonal 'rotating' lower members studied by S. P. Hendricks and others,<sup>2</sup> but with the hitherto unobserved feature of four layers per cell in alternate pairs inclined approximately  $48^\circ$  to the  $c$  plane This leads to a negative birefringence unlike that of all other long chain compounds

#### Heat of Dissociation of Nitrogen

THE value of the heat of dissociation of nitrogen has formed a lively subject of controversy in the past few years All values from 19 to 7 volts have been given by various workers for the dissociation potential I have recently determined this value by examining the absorption spectrum of  $\text{N}_2\text{O}$  in a manner which has already been explained in my note on the spectrum

of  $\text{SO}_2$ .<sup>1</sup> The value comes out to be 8.8 volts or 203 kcal

The absorption spectrum of  $\text{N}_2\text{O}$  is perfectly continuous, with no trace of bands, as in most saturated compounds From microphotometrical study of the absorption spectra taken at different pressures, I found that the absorption begins at  $\lambda 2740$ , corresponding to 104.4 kcal Assuming that this corresponds to a photochemical breaking up of  $\text{N}_2\text{O}$  into NO and N (this assumption is supported by other arguments), and utilising other thermochemical data, the heat of dissociation comes out as 203 kcal This value is in good agreement with the most recent results of Turner and Samson,<sup>2</sup> and Tate and Lozier,<sup>3</sup> obtained by other methods, and is certainly the most accurate value of the heat of dissociation of  $\text{N}_2$  obtained so far

#### Decomposition of Hydrogen Peroxide by Catalase

IN his recent statistical calculations on the decomposition of hydrogen peroxide by catalase, Prof J. B. S. Haldane estimated<sup>1</sup> that the mean life of an active catalase-hydrogen peroxide molecule is about  $10^{-7}$  second, and the velocity constant for the union of catalase and hydrogen peroxide exceeds  $7 \times 10^8$

Work at present in progress, consisting of a comparison of the photochemical decomposition with the enzyme reaction, indicates that the latter may have to be regarded as a *chain reaction*, in which the active centres of the enzyme function only by starting the chains, which then continue in the bulk of the solution, or on other surfaces

This view becomes more credible in the light of recent work by Allmand and Style, who conclude that even in dilute aqueous solutions of hydrogen peroxide "the photochemical, and hence presumably the thermal reaction, is a chain reaction", and "the reaction chains must be exceedingly long—of the order of  $10^4$  to  $10^7$  links"

According to this view, the inhibition of enzyme reactions may be due in some cases to the breaking of the reaction chains by the inhibitors, as in numerous photochemical reactions.

Zeile and Hellstrom have shown that iron-porphyrin compounds form the active centres in catalase, and, in 1931, I observed that the action of iron compounds in certain inorganic systems analogous to enzyme systems can best be explained by the chain-reaction hypothesis,<sup>2</sup> a view which was put forward independently by Prof. Haber a few weeks later<sup>4</sup>

I conclude that in view of these facts a modification may have to be introduced into Prof. Haldane's interesting calculations on catalase

#### Electrochemical Periodicities

THE interesting observation of periodicity at a platinum anode in a solution of dilute sulphuric acid containing dissolved hydrogen, recently reported by Butler and Armstrong,<sup>1</sup> recalls an unpublished experiment which I made in 1927 during the course of a series of investigations of this subject

I found that when copper was made the cathode in 10 per cent nitric acid at low current densities (about 5 ma per sq cm), its potential oscillated continuously in periods having a duration of about 1 second and an amplitude of about 0.1 volt. No gas was evolved. This case is complementary to that reported by Butler and Armstrong, for, whilst their observations refer to an anodic process in a reducing solution, mine are concerned with a cathodic process in an oxidising solution. I assumed the periods to be connected with the formation of reduction products of nitric acid—probably ammonia.

Regarding the cause of the periodicity, my experiments on anodic reactions (described fully in "Protective Films on Metals" London Chapman and Hall) showed that the phenomenon appears when the electrode has almost equal chances of being 'passive' or 'active', or, in general, of being coated or not with a more or less protective film. The phenomenon also appears at the cathode when two reactions are equally probable, and all the evidence points to a critical concentration of ions which must be attained in order to effect the change from one state to the other, a fresh period begins each time the critical concentration is reached by diffusion.

The existence of periods at both anodes and cathodes may be expected by analogy, therefore, when the oxidising or reducing tendency of the electrode is approximately equal to the reducing or oxidising power of the solution. Two years ago I commenced preliminary experiments with the intention of leading to a general study of the cathodic reduction of oxidising solutions and the anodic oxidation of reducing solutions from this point of view, but the work had to be discontinued.

#### Dependence of Angle of Contact on the Constitution of Adsorbed Organic Compounds

IN the course of an investigation conducted on behalf of the Broken Hill South, North Broken Hill, Zinc Corporation, Electrolytic Zinc, Mount Lyell, and Burma Corporation Mining Companies, measurements were made by two of us of the effect of xanthates on the angle of contact at a line of triple contact, mineral-water-air. These have been reported in Technical Publication No. 461 of the American Institute of Mining and Metallurgical Engineers. A trace of potassium ethyl xanthate, dissolved in the water, leads to an angle of contact which is independent both of the concentration of the xanthate and the nature of the mineral. Another compound containing the ethyl group, sodium di-ethyl dithiophosphate, leads to an identical angle of contact. At the time of publication of the above paper it was uncertain whether this was merely a coincidence.

Under an arrangement with the University of Melbourne, the measurements have now been extended by the third author (E. E. W.) to include several other organic types. It has been proved that several ethyl derivatives containing the -SH group lead to this same angle of contact ( $60^\circ \pm 2^\circ$ ). Moreover, each alkyl or aryl group exhibits a characteristic angle of contact, which apparently is independent of the nature of the polar group of the adsorbed molecule.

During the course of this work the contact angles at the surfaces of a large number of minerals and metals have been investigated.

It is inferred that the mineral or metal surface is covered by a unimolecular film of the thio-compound, in which the alkyl group is oriented outwards, and

that the alkyl groups are packed as closely as their size will permit.

Details of the investigation will be published elsewhere.

#### Rediscovery of *Caloprymnus campestris* (Marsupialia)

SINCE Sir George Grey sent the three original specimens to the British Museum, in 1843, this interesting marsupial, one of the 'Rat-Kangaroos' of the subfamily Potorominae, has been completely lost to science. There is a somewhat doubtful record of it in 1878, but no specimen of the animal exists in any museum in Australia, and there was much to justify the generally accepted view that the animal was extinct.

Following the preliminary announcement by me in September last<sup>1</sup> that *Caloprymnus* was still extant, field work was undertaken in the locality of the first occurrence, with considerable success. The animal has now been shown to have a wide but sporadic distribution in the great area of sandhill and gibber plain country enclosed by the Diamantina and Cooper Rivers between latitudes  $24^\circ$  and  $29^\circ$  south (approximately).

Evidence obtained indicates that *Caloprymnus* has had a long and probably uninterrupted tenure of the area, but that normally its occurrence is very sparse. The passing of drought conditions has apparently provided a stimulus, resulting in a considerable local increase in its numbers.

A series of specimens in several developmental stages was secured, and a restatement of the characters of the animal and of its habits and economy is being prepared. The locality from which Sir George Grey's specimens come is uncertain. Any information on this and allied points, by students in England who have had access to Grey's papers, especially his correspondence with Gould, would be welcomed by me.

#### Heterospory and the Angiosperms

PROF. RUGGLES GATES in his interesting letter on this subject<sup>1</sup> compares the size of the microspore and megaspore *mother-cells* in Angiosperms, and finds that the former are in some cases larger than the latter. But is the size of the *mother-cells* material to the question? Surely it is the relative volume of the mature and functional microspores and megaspores which determines heterospory. In the heterosporous Pteridophytes there may be little or no difference in the size of the respective *mother-cells* up to the time of their division.

As a palaeobotanist, I have no prejudice in favour of the origin of the flowering plants from heterosporous Cryptogams. The fossil evidence so far lends no support to this classical hypothesis. But it does seem to me that the existing Angiosperms (and Gymnosperms also) do, as a matter of fact, show in general a marked heterosporous differentiation, if one compares their pollen grains and embryo sacs when functionally mature.

## Research Items

**Bride Wealth among the Hehe, Tanganyika Territory**—In *Africa* (vol 5, No 2) for April, Mr G. Gordon Brown analyses the custom of the bride-price, or bride wealth as he prefers to call it, with reference to its several functions in relation to the observances connected with marriage. The primary function of *mafungu* is to stabilise marriage. Its amount is one of the essential matters settled at the betrothal ceremony, when relatives of both families are present. The last word lies with the father of the bride, who first names the amount and may or may not agree to any change afterwards suggested by the relatives on his side. The groom does not pay the amount out of his own wealth, but is assisted by his kinsmen, the father or father's family usually supplying two-thirds of the amount, and his mother or mother's family one-third. It is supposed to be paid to the bride's father on the day of the wedding. He keeps two-thirds and gives one-third to the bride's mother. Until the *mafungu* is paid, the marriage is not considered to be binding. Its payment is, in fact, necessary to legalise the marriage. Unless it has been paid, a husband cannot sue for adultery compensation. In case of divorce, the *mafungu* must be returned. The interest of the family in the *mafungu*, their co-operation in raising it, and the difficulties of collecting it when returnable on dissolution of the marriage, give the families an interest in maintaining the marriage and endeavouring to avert a possible divorce. In certain cases, such as cross-cousin marriage, the *mafungu* is less, as the bond of kinship makes it unnecessary to require so large an amount to secure the desired stability.

**Warfare in Eddystone Island**—Mr A. M. Hocart has described (*J. Roy. Anthropol. Inst.*, 61, pt 2) the methods of warfare of the inhabitants of Eddystone of the Solomons. The natives still go armed, although the spear and shield are not now carried, but a man will scarcely abandon his tomahawk, which is, besides, a handy tool for husking coco-nuts and cutting branches. It has displaced the original weapon, a paddle-shaped club. Warfare may be divided into wars of revenge and head hunts. The two chief causes of internal strife are murder and adultery. Heads are not caught at random, but for the definite purpose of inauguration, the term used in the vernacular meaning 'to moisten' or 'to wet', presumably with blood, the occasion being the inauguration of new canoes, new communal houses, new skull houses, the death of a chief, and the release from confinement of a widow. Ysabel became the favourite hunting ground for the people of Eddystone. Turtle expeditions were often pretexts for head hunts. Slaves were also captured, but when captured a slave is really supposed to be dead. Cannibalism appears to have been little practised. War canoes are no longer in existence, but formerly there were several in each district. Ceremonies were carried out before departure. If an enemy made a raid on the island, revenge was taken by attacking the aggressors and carrying off a captive, who was sacrificed. A festival was held in honour of a manslayer after the return of an expedition, for which the giver of the feast had to collect food, mainly pigs and taro. A feast was also held after the first successful raid of a new canoe.

**Duckbilled Platypus**—In *Blackwood's Magazine* for May (p 717), H. A. Roome gives some interesting notes on his attempts to keep the duckbilled platypus in captivity during a stay in Tasmania in 1888. The

animals' behaviour as described does not give the impression of low mentality at all, they displayed a disconcerting activity in climbing wire-netting as soon as confronted with it, and a pair which were kept for about a week exhibited playfulness which would have been noteworthy in any mammal, gambolling together not only in the water of their tank, but also among the weeds of their enclosure. It is unfortunate that the duckbill, unlike its fellow-monotreme the echidna, is so delicate in captivity, the pair above mentioned having so soon succumbed although supplied with natural food from a pond. Bennett did better with a pair of young ones in 1860, allowing them the run of a room and feeding them on artificial food, yet they lived little more than a month. A few years ago, however, a platypus was successfully taken to America and exhibited, being fed on shrimps and earthworms. Probably an experienced convoyer of the more delicate insectivorous birds would succeed with this most interesting mammal.

**Development of the Vertebral Column**—What may perhaps be called the standard account of the development of the vertebral column in the Gnathostomata, since it occurs in many textbooks, is based upon the investigations of Gadow and Abbott. Subsequent work has shown that this account is in need of revision in various important points. Prof E. W. MacBride has performed a useful service in surveying the researches into this problem in Elasmobranchs (Ride-wood), Teleostei (Ramanujam), Amphibia (Mookerjee), Aves (Pücher), and Mammalia (Dawes) which were carried out in the Department of Zoology at the Imperial College of Science (*Biological Reviews*, April 1932). In a brief notice it is not possible to refer to all the details dealt with in what is itself a condensed review. The vertebræ in most Elasmobranchs, save a few primitive forms, are not chordacentrous but their centra are perichordal. They are also perichordal in all the higher groups, and the arcualia—basidorsals, basiventrals, and ribs—are developed in the myocommata. There is a much closer fundamental agreement between the various groups than was generally supposed, and not the great break between Amphibia and Amniota. The important difference between these groups is not in the method of formation of the vertebræ, but in the fact that in the latter alone (or at any rate in the Mammalia) five anterior segments of the vertebral column fuse with the skull. The paper is illustrated by forty-eight text-figures, but it is a pity in so useful a work that some of them are badly drawn, and the reader is not aided in tracing the originals, as there is no direct acknowledgment of their origin.

**Size and Shape Factors in Fruits**—Plant varieties are often distinguished by the size or shape of their fruits, but relatively little is known regarding the genetics of these differences. An interesting contribution to the subject has been made by Dr E. W. Sinnott (*J. Heredity*, vol 22, No 12), who crossed varieties of *Cucurbita pepo*. In some races the fruits may be five times as long as their diameter, while in those with flat fruits the width may be three times the length. Some of the types isolated also differed greatly in size of fruit. In crosses, certain shape differences showed sharp monohybrid segregation in  $F_2$ . A study was made of the relation between size and shape in certain crosses. Two pure lines which differed markedly in fruit size and shape were crossed. One had a small spherical or pea-shaped fruit

(average diameter, 11 cm, average weight, 700 gm) The other had a large disc-shaped fruit (7 cm  $\times$  18 cm, 1300 gm weight) The disc shape is completely dominant, with a 3 : 1 ratio in  $F_2$ . But the  $F_2$  discs and spheres were of the same average weight (about 1030 gm) The  $F_2$  fruits showed greater variability in weight than the  $F_1$ , suggesting multiple factors for size. Thus there was present a single pair of factors governing fruit shape, presumably acting through control of growth correlation, and a series of factors governing volume or weight, and probably effective through control of the amount of material at the command of the growing fruit. The size factors appear, moreover, to be independent of the shape factors, and there is no evidence for the existence of genetic factors directly controlling single dimensions.

**The Magma of Vesuvius**—In *Die Naturwissenschaften* for April 29, Dr A. Rittmann discusses the origin of the magma represented by the lavas of Vesuvius. The prehistoric lavas of Monte Somma can be satisfactorily regarded as *vicoite* (sanidine bearing leucite-tephrite) and its leucocratic and melanocratic differentiation products, leucite-phonolite and *ottajanite* respectively. Leucite-phonolite was last erupted in A.D. 79, when Pompeii was overwhelmed. Since then, Vesuvius has developed from a magma having the composition of leucite-tephrite. No significant variation has been observed in the lavas from 1631 to the present day. Variation diagrams show that the Vesuvius magma lies within the range covered by the earlier Somma magmas. It is clear, however, from the chemical and mineral characters, that the Vesuvius magma cannot be a residual magma produced by the separation of early formed crystals from the *vicoite* magma of Somma. Dr Rittmann suggests that the difference can be ascribed to assimilation of the Triassic dolomitic limestone that underlies the volcanic pile, accompanied by crystallisation differentiation. The separation and sinking of aggregates of augite, biotite, olivine, and anorthite, represented by ejected blocks of *missourite*, *pughanite*, *sebastianite*, *biotite-pyroxenite*, and *olivine-pyroxenite*, would remove from the system *vicoite* plus dolomitic limestone just those constituents required to leave a magma relatively impoverished in magnesia and silica and enriched in alkalis and gases. The hypothesis is one which will readily commend itself to most petrologists. It should, however, be noticed that assimilation of carbonates does not here provide an origin for the alkali-rich character of the original magma of Somma, but only for the change in composition from *vicoite* to leucite-tephrite.

**The Shyok Ice Barrier**—In view of the disastrous flooding from the Shyok lake in the Karakoram in 1929, a note on the present state of the ice dam is of interest. It was visited in 1931 by Capt C. E. C. Gregory, who records his observations in the *Himalayan Journal* for April 1932. The snout of the Chong Kumdan glacier which dams the valley was then about 1500 yards wide and about 200 feet high, and the lake behind it had a surface area of over thirty miles, and was standing 30-40 feet below its highest level. The ice is apparently in a state of retreat, but there is little loss of water from the lake by percolation through the dam. The deep channel cut in the ice by the burst of 1929 had completely healed in a year. Estimating from the steady rise in the waters of the lake, Capt Gregory believes that it will overflow or burst the barrier again in 1932. Major K. Mason, discussing the problem from the data available, thinks that degeneration of the glacier snout

will allow heavy percolation of water and so relief of pressure, and provided the normal high level of water in the summer of this year is safely passed, there will be no further danger of a burst for many years. He is not, however, so sure as Capt Gregory of the probability of a serious burst during this summer.

**Hair Hygrometer**—The hair hygrometer is the simplest type of instrument for indicating the relative humidity of the air without the necessity either for calculations or the use of charts. Being dependent for its functioning on the reproducibility of the hygroscopic properties of hair, this form of hygrometer needs checking from time to time by reference to a ventilated wet and dry bulb hygrometer or a dew point apparatus. Messrs. Negretti and Zambra have recently placed on the market a compact form of hair hygrometer. The instrument is of circular pattern, measuring 4 inches in diameter by  $1\frac{1}{2}$  inches in depth, and is described by the makers as being a wall or pocket type. The scale is enamelled on metal, and therefore not liable to distort with humidity changes as sometimes happens with paper scales. The operating mechanism is simple, consisting of a bundle of hairs anchored at one end, passing over a pulley, and coupled at the other end to a variable throw crank. Tension is maintained by a spring. The variable throw crank permits of control on the magnification of the movement, so that the scale can be adapted to a particular bunch of hair. The usual form of zero adjustment is provided. A few precautions are necessary in the use of an instrument of this type: (1) it should not be exposed to direct sunshine, otherwise errors will be introduced, due to the warming up of the blackened case of the instrument and the lowering of the relative humidity of the air inside, (2) time must be allowed for equilibrium to be reached if the instrument is taken from an atmosphere of one humidity into another of a different humidity, since the air has to diffuse into the instrument through slits in the case.

**Origin of the  $\gamma$ -Rays from Actinium Emanation**—Two observations have been made recently on the properties of the radioactive gas actinon which afford evidence for the hypothesis that  $\gamma$ -rays have their origin in transitions of  $\alpha$ -particles inside an excited nucleus, and not in the movement of electrons (*Roy Soc. Proc.*, May). The first consists in an observation by W. B. Lewis and C. B. Wynn-Williams with an electrical counter on the  $\alpha$ -particles from actinon, which has shown that these are heterogeneous, one of the two groups emitted has a range in air of 5.6 cm, and the other a range of 5.2 cm. On the above theory of the  $\gamma$ -rays, the difference in energy,  $3.6 \times 10^5$  electron-volts, should also appear as a  $\gamma$ -ray quantum in the actinon-actinium A disintegration. That this probably occurs has been shown by Lord Rutherford and B. V. Bowden by a second set of experiments, in which the radiation from a current of air containing actinon was examined with a Geiger-Müller tube counter, and  $\gamma$ -rays of about the expected penetrating power found. Before these observations it had been supposed that the emanation emitted only  $\alpha$ -rays, but in addition to the  $\gamma$ -radiation, a weak  $\beta$ -radiation, probably due to internal conversion of the  $\gamma$ -rays in their escape from the nucleus, has also been detected with an electroscope.

**The Theory of Radiation**—This problem, an outstanding example of the incomplete success of modern quantum theory, is discussed at some length by Prof. C. G. Darwin in the May number of the *Proceedings of the Royal Society*. An essential point in the modified theory which he outlines is that the general similarity

of electrons and photons in behaving both as particles and waves should be recognised. The difficulties which arise from the apparent annihilation of a photon when it is absorbed can be neglected, at least in the first instance, but it is necessary to make an abrupt departure from earlier work by treating the electric force in an electromagnetic wave as an unobservable quantity, it is not considered identical with a static electric force, or even with the force in wireless waves when they involve a large number of photons, but is taken to be a quantity like the  $\psi$  of wave-mechanics, and a set of six components of the electric and magnetic vectors adopted as wave-functions. Development of this idea then leads, as for the electron, to the difficulty that states of negative energy should arise, and, as appears also to be done now for the electron, this is deliberately ignored. Prof Darwin remarks that the troubles of the quantum theory are apparently increased by this, but that it is usually found that the best hope of resolving a deep difficulty is to extend its application as far as possible. Further elaboration furnishes the angular momentum of the quantum, analogous to the spin of the electron, and with it an example of the duality of the quantum theory, in insisting both

that the angular momentum of a system must be an exact multiple of the quantum and that it is impossible to measure it to the nearest quantum. The remainder of the paper deals in a preliminary way with the perturbation of a photon by an electron. In the same number of the *Proceedings*, Dr P. A. M. Dirac gives an account of a quantum theory in which the interactions between particles take place by means of vibrations of an intervening medium transmitted with a finite velocity, and Prof Wasastjerna discusses the quantum statistics of X-rays.

#### Natural Regulators of Protein Metabolism in Plants.

—Mothes has published a highly interesting note on this subject (*Naturwiss.*, 6, 102, 1932) in which he claims that a regulator can be extracted from plants, which largely determines whether proteins are built up or broken down. The substance is acetone soluble, and it activates protein hydrolysis when in a reduced form but not when in its oxidised form. In the former case, it reacts with sodium nitroprusside to indicate a sulphhydryl grouping. Its further investigation obviously promises a considerable addition to our knowledge of the vexed questions surrounding protein synthesis in plants.

### Astronomical Topics

**Magnetic Disturbance of May 29-30**—A considerable magnetic disturbance was registered at the Greenwich magnetic station of Abinger on May 29-30 last. The ranges of the three elements during the disturbance, which began rather indefinitely at about 11<sup>h</sup> on May 29, were as follows: declination 35', horizontal force 340  $\gamma$ , and vertical force 265  $\gamma$ . This disturbance of 'storm' range is the largest recorded at Abinger since March 1929. The sun's activity is now definitely declining towards the minimum phase of the eleven-year cycle, when magnetic disturbances of this magnitude are usually very infrequent.

At the time of the commencement of the 'storm', a fairly conspicuous spot was about 3 days past transit of the sun's central meridian. This suggests a connexion with the storm, though in appearance and size the sunspot was not unusual. On the few occasions at Greenwich when breaks in cloudy skies permitted the spot to be observed spectroscopically (when it was near the centre of the sun's disc) the hydrogen atmosphere in the region of the spot was distinctly active but not to an abnormal degree.

**The Arizona Expedition for the Study of Meteors**—For many years observations of meteors have been actively carried on in the United States. As the results seemed to indicate that many meteors were moving with hyperbolic velocities, and were therefore visitors to the solar system from the stellar regions, it was seen that statistical study would increase our knowledge of the character and amount of the matter that exists in interstellar space, which is of importance in many problems relating to the star system. Accordingly, Prof H. Shapley, with the co-operation of Dr Opik and Prof Boothroyd, has organised an expedition to the clear air of Arizona, for the statistical study of meteors (*Proc. Nat. Acad. Sci.*, Jan 15, 1932). The Lowell Observatory is accommodating one of the parties, while others are placed at distances of 2 miles and 23 miles from it, there is thus material for obtaining the real paths of doubly observed meteors. Each observer has the position of his eye fixed by looking through a tube, and the area of sky visible is limited by a square opening, through which a region

80° by 80° is visible. The opening is crossed by bars, which are used to fix the tracks more exactly. There is a rocking mirror that is used for part of the time to determine the speeds of meteors. A star appears as an ellipse in the mirror, but a meteor appears as a wavy curve, the distance between the crests of the waves gives the speed. There is good reason to hope that the results will lead to a great increase of our knowledge of meteors.

Mr. J. P. M. Prentice, director of the Meteor Section of the B. A. A., notes that there is still plenty of scope for amateur work on meteors, the Arizona expedition is mainly to secure general statistics, whereas his section keeps watch on special showers, such as the Perseids, Leonids, etc. These showers are known to belong to the solar system, whereas the special concern of the American expedition is to investigate the cosmical meteors, which come from outside. Of course, the observations must include all the meteors seen, since their relation to the solar system can be inferred only after subsequent discussion.

**The Star 70 Ophiuchi**—This is an interesting double star which has for a long time perplexed computers owing to apparent irregularities in the motion, this caused suspicion that there might be a third unseen companion, but no satisfactory verification of this supposition has hitherto been obtained. *Lick Bulletin* No. 443 contains a study of this star by Mr. L. Berman. He has examined the radial velocity of the brighter component, and finds that, in addition to the large wave with a period of 88 years due to the known component, there are decided indications of a smaller wave with a period of 18 years, which he ascribes to a small companion (the mass of which is estimated to be between one-tenth and one-fifth of the sun's) revolving round it. The inclination of this orbit is concluded to be nearly 90°. He notes that the dynamics of this system, if it contains three stars of comparable mass and comparable size of orbits, would be extremely complex, and much work would be required before the exact effect on the motion of the visible pair could be estimated. The parallax is found to be 0.179".

## Congress of the South-Eastern Union of Scientific Societies

THE annual congress of the South-Eastern Union of Scientific Societies was held at the Civil Service Commission, Burlington Gardens, W.1, on June 1-4, the presidential chair being occupied by Dr R E Mortimer Wheeler, keeper of the London Museum. Recalling to mind that the Emperor Augustus was probably the first museum-curator of a kind, as recorded by Suetonius, Dr Wheeler said that the goal of archaeological research is not only the collection of potsherds and the like, but also the reconstruction therefrom of all that has in the past been most vital in human thought and action. The story of Grettir the Strong is that of one of the earliest excavators known to history. Determined to defy the ghost of Kar the Old, he ordered that tools should be made ready for digging up the mound of Kar, and his companion having been scared away by the ghost, Grettir worked alone and brought out much treasure of gold and silver. He also kept silence about it, his enthusiasm not being entirely of an unselfish character. Treasure-hunting remained the main objective until well into the nineteenth century. The despoiling of barrows died hard. In 1844 the *Archæological Journal* recorded the opening of eight barrows in two hours on Breach Downs in the presence of a company assembled for the purpose. It was for them a holiday diversion to see weapons, urns, beads, bones, or glass vessels brought to light and scattered around. No wonder that archæology in its early days had to fight for recognition as a scientific pursuit worthy of intelligent minds.

The amateurishness of the excavations of early Victorian times was no doubt responsible for the low estimation in which archæology was held, but the situation was completely altered with the arrival on the scene of General Pitt-Rivers, who late in life came into possession of a fortune and a large estate in a district of unsurpassed antiquarian interest. It was in Cranborne Chase that the science of archæology was really discovered. British enterprise in the science is now at the full-tide. Not only in our own country but also all over the world, the spade and fork are in capable and energetic hands. But more trained observers and workers are needed. There is lack of the means by which such training can be arrived at. There is now an opportunity such as can never again be seized. An Institute of Archæology is needed, and with the building of a new University of London it is imperative that provision be made for such an Institute. Dr Wheeler appealed for support of the scheme which has been promulgated by Sir Charles Peers and others.

In the absence of Sir J. Arthur Thomson, a lecture was delivered by Dr Landsborough Thomson on bird migration, a subject which gives rise to many surmises but about which very little is really understood. The ringing of migrant birds has yielded a good many facts, but at present the return of only some 3 or 4 per cent of marked birds has been noted. Migration cannot be regarded as the result of reasoning. There is no compulsion which makes swallows, for example, breed in England in preference to South Africa, where they find a summer in our winter time. They can have no actual knowledge of our winter climate. We call the conduct of migrant birds instinctive and inherited, but this explains nothing. The true homing instinct is shown in the return of some to their old breeding-places year after year. In this they are aided by their powers of sight, but the actual reasons of their return are unknown. It is one of the great problems yet to be unravelled.

In the Geological Section, Prof H L Hawkins dealt with "Some Episodes in the Growth of South-Eastern England." East of a line joining the Wash with the head of Lyme Bay, the area is almost entirely covered by Cretaceous or later deposits, but just outside it palæozoic rocks, the pre-Cambrian and Carboniferous, reach the surface in South Leicestershire and the Mendips, and they extend into the area under the newer cover of rocks. These two ancient series of rocks give a clue to the foundations of the area. The Charnian line passes from Leicestershire in a south-easterly direction under east London, and the Mendip line takes a mainly easterly course linking Frome with Dover. The influence of the latter is seen in the east and west trends of the later rocks. The southern edge of the palæozoic massif under the North Downs is as clearly defined as is its western edge by the Mendips and their extension through Pembrokeshire. Assuming a northern edge determined by the Midland ridge and an eastern margin of similar rocks under the North Sea, we find postulated a nearly square basin, bounded by palæozoic ridges, with its corners at London, Bristol, the Wash, and near Ironbridge, and at each corner where the intersecting ridges cancel out are the exits of the chief rivers of the basin. In this basin Triassic and Jurassic rocks were developed on a grand scale. Prof Hawkins then gave his conception of the landscape of the area in Triassic times, the middle floor of the area, and passed on to the upper floor of Cretaceous time, when the uplift excluded the chalk sea. The south-easterly dip of the older systems then caused the elevation of the western parts before the eastern had emerged, thus resulting in a shoreline running north-east by south-west, which crept towards Dover as the uplift progressed.

In the Botanical Section, Mr J Ramsbottom, of the Natural History Museum, gave a paper on "Fungi as Scavengers", showing how humanity is indebted to these lowly organisms for many of the comforts of civilisation, and Mr A J Willmot followed with a paper on "The London Flora", as it was and as it now is.

Old-world enjoyment of life in the Middle Ages was the subject of "Medieval Games and Gaderings", by Dr W E St L Finny, and in the Zoological Section, Mr Hugh Main showed much of his excellent photographic work in "The Camera as a Naturalist's Recorder". Original slides from his own photographs illustrated Mr E J Bedford's "Some Ground-nesting Birds".

"Town and Country Planning" was dealt with by Mr G L Pepler in the Regional Survey Section, and it was pointed out that town-planning really includes that of rural districts, for the planning of one of the latter is in order to provide against irregular and bad planning when such parts come to be built over.

Some remarkable slide-pictures by Mr M Maxwell were shown by Capt Guy Dollman in his lecture on "Great Game Animals of Africa", and his lecture was a model of what a carefully prepared and well-delivered lecture should be.

Excursions to suit all scientific tastes occupied each afternoon, visits to the London Museum, the Natural History Museum, Zoological Gardens, Swancombe, Abbey Wood, Hampton Court, Burnham Beeches and other places being made. A four-hour cruise in the Port of London was a popular feature. Under the leadership of Mr A Farquharson, a survey walk was made in Westminster and Pimlico.

Prof E J Salisbury was elected president of the Congress for 1933, which will be held at Norwich.

## The Royal Observatory, Greenwich

### ANNUAL VISITATION

THE annual visitation of the Royal Observatory, Greenwich, took place on Saturday last, June 4, when the Astronomer Royal presented his Report to the Board of Visitors on the work of the Observatory during the past year. The Report begins with a statement of the progress that has been made in the construction of the two new instruments and the buildings for them, which are situated in the magnetic enclosure, at some distance from the present buildings. The large concrete block, 15 ft square and 9 ft thick, on which the transit circle will rest, is in position, and the piers for the collimators, each distant fifty feet from the instrument, are in position. Messrs Cooke, Troughton and Simms have already completed the three objectives, each of 7 in aperture. The transit micrometer is to be motor-driven. The circles will be 24 in in diameter. It is proposed to construct one circle of glass, the divisions will be read through the glass, and will be protected at the back by a metal plate, to obviate the need for cleaning, it is found that this is apt to cause slight changes in the divisions in the course of time. The Johnstone Yapp 36-in reflecting telescope is being constructed by the firm of Sir Howard Grubb, Parsons and Co. A large part of the mechanical work is completed, also the smaller mirrors. The mounting will be of the modified English type. The building of the dome is far advanced.

The usual observations have been carried on with the Transit Circle. The moon was observed on 74 days, the correction indicated to Brown's longitude of the moon in 1931 is  $+4.8''$ , it has been steadily diminishing since 1924, when it was  $+7.2''$ , the correction to the latitude has remained nearly constant at about  $-0.8''$ . The proper motions of stars in Boss's General Catalogue have been revised—those of the remaining stars brighter than mag 8.0 in the zone N Decl  $32^\circ$  to  $40^\circ$ . 311 double stars were measured with the 28-in equatorial, 55 of them were closer than  $0.5''$ . 1223 plates were taken for stellar parallax with the 26-in equatorial, 1128 plates were measured, and parallaxes of 37 stars deduced, results were given in *Monthly Notices* of the Royal Astronomical Society for November last.

The programme of work on star temperatures has been carried on with the 30-in reflector, a volume is in press containing the absolute colour temperatures of 25 standard stars and 38 other stars. 106 plates were taken with the astrophotographic equatorial for the determination of proper motions in the Greenwich zone, which extends from Decl  $64^\circ$  to the pole. This work has now been completed and is nearly ready for press.

Photographs of the sun were obtained on 261 days, the missing days are filled in with plates from the Cape and Kodaikanal. Sunspot activity has continued to diminish, and the minimum is expected in a year or two. Observations were made with the spectrohelioscope on 154 days, measures of radial velocities of flocculi have been published in *Monthly Notices* of the Royal Astronomical Society.

The Report describes the preparations for the solar eclipse of Aug 31 next, Dr J Jackson and Mr C R Davidson are going to Parent, on the Canadian National Railway, which will also be occupied by a party from Ottawa Observatory. Mr Worthington has lent a 6-in lens of 45 ft focus for photographs of the corona, various spectroscopic researches will be carried on.

A determination has been made of the longitude and latitude of the Abinger magnetic observatory, they are  $0^\circ 23' 12.06''$  W,  $51^\circ 11' 5.17''$  N. The

magnetic elements for 1931 are Decl  $12^\circ 13' 7''$  W, Hor Force 0.18544, Vert Force 0.42923, Dip  $66^\circ 38' 1''$ .

The following weather statistics refer to the year ended April 30, 1932, the averages with which they are compared being those of the 75 years 1841–1915. The mean temperature had the exact average value  $49.5^\circ$ . The maximum was  $81.2^\circ$  on July 12, the minimum  $20.6^\circ$  on Dec 31. There were 49 days of temperature  $32^\circ$  or lower. The mean daily movement of the air was 281 miles, which is 4 below the average. The maximum was 691 miles on Dec 4. The duration of bright sunshine was 1180 hours, there were 87 entirely sunless days. The rainfall was 23.89 inches, which is 0.35 below the average, the wettest and driest months were August and February, with 6.27 and 0.29 inches respectively.

Observations for time were made with the small reversible transit instrument on 63 nights. On Feb 18 last, Shortt No 11 was adopted as the standard sidereal clock instead of Shortt No 3, the latter has been fitted with a new invar pendulum and bob.

The rhythmic time-signals have been sent to Rugby at  $10^h$  and  $18^h$ , they are now preceded by warning signals. The usual comparison of time-signals with those of Paris, Nauen, Annapolis, and Bordeaux is given in the report, they are, in the mean, later than Greenwich by  $0.007^s$ ,  $0.031^s$ ,  $0.026^s$ , and  $0.015^s$  respectively.

The Astronomer Royal observes that this is his last annual Report to the Board, and gives a summary of the work carried on at the Observatory since his appointment in 1910.

## University and Educational Intelligence

**BIRMINGHAM**—Dr L J Wills has been appointed to the chair of geology, to succeed Prof W S Boulton, who retires at the end of the current session.

Mr William Gemmill, honorary surgeon to the Queen's Hospital, has been appointed joint professor of surgery, to succeed the late Prof William Billington.

**CAMBRIDGE**—It is proposed to appoint a Syndicate consisting of the Vice-Chancellor, Dr E D Adrian, the University Treasurer, Prof R H Fowler, Mr F T Brooks, and Mr R E Priestley to consider the organisation of the research institutes in the University and their relations to the University and its departments, and to report to the University by the end of the Lent Term, 1933.

**LONDON**—Prof H V A Briscoe, since 1921 professor of inorganic and physical chemistry at Armstrong College, Newcastle-on-Tyne, has been appointed to the chair of inorganic chemistry at Imperial College (Royal College of Science) as from Oct 1, 1932.

Mr S G M Ure, since 1921 lecturer in chemical engineering at the Imperial College, has been appointed reader.

The title of professor of physical chemistry in the University has been conferred on Dr Samuel Sugden, in respect of the post held by him at Birkbeck College.

Prof F A von Hayek has been reappointed to the Tooke chair of economic science and statistics tenable at the London School of Economics.

The Dunn Exhibitions in Anatomy and Physiology for 1932 have been awarded respectively to Mr J E Spalding and Mr W N Mann, both of Guy's Hospital Medical School.

**WALES**—Applications are invited for the following scholarships. The Mrs John Nixon Research Scholarship in the Department of Medicine and

Medical Pathology, value £150, the Lord Merthyr Research Scholarship in the Department of Surgery, value £200, and the Ewen Maclean Research Scholarship in the Department of Obstetrics and Gynaecology, value £150. Applications must reach the Registrar, University Registry, Cathays Park, Cardiff, not later than Sept 1

A FELLOWSHIP for research in aeronautics is being offered by the Armourers and Brasiers' Company, the tenure of which will be two years and the annual value £300. Applications must reach the Clerk to the Company, Armourers' Hall, 81 Coleman Street, E C 2, by, at latest, June 30

APPLICATIONS are invited by the Agricultural Research Council for three agricultural research scholarships, each of the yearly value of £200 and tenable for not more than three years, and for two veterinary research fellowships, value £300 a year and tenable for not more than three years. All candidates must be nominated by a professor or lecturer of a university, college, or medical school, or by the director of a research institute. Forms and full particulars can be obtained from the Secretary, Agricultural Research Council, 6A Dean's Yard, S W 1

THE education of American Indians and Negroes and natives of the principal outlying possessions of the United States—Hawaii, Porto Rico, the Philippines, and Alaska—is dealt with in *Bulletin*, 1931, No 20, of the Office of Education, Washington. This survey of American experience during the past ten years of educational problems arising from the necessity of integrating people of widely different racial origin, traditions, and beliefs in a new social and economic order will be read with interest by educational administrators in other parts of the world, notably in the African dependencies of Great Britain. Educational policies have aimed at preserving the best in native cultures, as well as the special gifts and talents with which, as individuals and groups, the native and minority peoples are endowed, and at transferring responsibility for administration, supervision, and instruction, as rapidly as possible, to the groups themselves. In Porto Rico and in the Philippines, such a transfer has practically been achieved. In Alaska, the Eskimos and Indians are still to a considerable extent dependent on the guidance of the missionary-teachers sent out by the authorities at Washington. Also in Hawaii, Porto Rico, and the Philippines, increasing attention is devoted to the 'practical' as distinguished from the academic side of secondary school objectives. In Porto Rico, under the pressure of the havoc wrought by a tornado, a new type of rural secondary school has been successfully introduced, in which the courses are based wholly on a vocational programme, with emphasis on those trades which are economically productive in the island.

### Calendar of Geographical Exploration

#### June 12, 1789 —The Mutiny on the *Bounty*

Capt William Bligh and a few companions who had been cast adrift in a small boat by mutineers reached Timor safely after having covered 3600 miles. Bligh had been sent out in 1787 in the *Bounty* to transport bread-fruit trees to the West Indies in the hope of introducing their production in those islands. Bligh rounded the Cape of Good Hope and discovered the Bounty group of islets south-east of New Zealand. A long stay was made at Tahiti and numbers of bread-fruit trees obtained, the *Bounty* then sailing for Java.

To the north of the Cook or Hervey group, Aitutaki island was discovered, and the ship put in for refreshments at the Friendly Islands. The crew considered these South Sea islands to be ideal and mutinied, hoping to enjoy a life of ease in one of them. Some of them became the ancestors of the Pitcairn Islanders. Bligh in the overladen boat, without a chart and with insufficient provisions, had to make his way from the Friendly Islands to Timor. He found a passage through the Great Barrier Reef in about 13° S and discovered Restoration Island.

#### June 15, 1869 —East Coast of Greenland

Koldewey's expedition sailed from Bremen, and with him was Payer, the future discoverer of Franz Josef Land. One vessel, the *Hansa*, got separated and crushed in the ice. Her crew built a house on an ice-floe, but this was broken by the splitting of the floe. They drifted, sometimes on their melting island and sometimes in boats, for more than 1100 miles, but finally reached the coast of Greenland in lat 60° N. The other ship, the *Germania*, had better fortune and Koldewey and Payer reached Sabine Island off the east coast of Greenland, named Kaiser Wilhelm Land, and partly explored Franz Josef Fiord.

#### June 17, 1853 —The North-west Passage

Capt R. M'Clure and his officers and crew arrived safely on board the *Resolute*, having been rescued by Lieut Pim from Banks Island, at a point where M'Clure was, in desperation, about to attempt the same southward journey to the Canadian coast which had proved fatal to Franklin's party. M'Clure had not only discovered but also traversed a north-west passage, partly by a land journey over ice. For this solution of a long-standing Arctic problem M'Clure was knighted and a sum of £10,000 was voted to himself, the other officers, and the crew. M'Clure in the *Investigator* left England in January 1850, with Collinson in the *Enterprise*, but they were accidentally separated before reaching Bering Strait. M'Clure penetrated the arctic from the west and passed the winter of 1850-51 at the Princess Royal Islands, only 30 miles from Barrow Strait. He found it impossible to reach Barrow Strait, though he could see it, because of heavy ice. He wintered on the north coast of Banks Island in 1851-52, and was preparing to abandon the ship in the spring of 1853, when help fortunately arrived. Collinson also succeeded in finding a north-west passage, and after three winters in the arctic returned home in 1854.

#### June 18, 1851 —The Niger and its Tributaries

Dr Barth reached the junction of the Faro River with the Benué, here half a mile wide, yet 415 miles distant in a direct line from its confluence with the Niger. He had set out with Richardson and Overweg, under government auspices, to explore the Niger region, starting from Tripoli. At the frontiers of Bornu the party separated, and Richardson and Overweg shortly afterwards died. Barth's extensive travels yielded a rich harvest of geographical, ethnographical, historical, and philological data. He explored the great bend of the Niger, visited the Tuareg tribes and the Hombori mountains, and reached Timbuktu. Thence he explored the Hausa States and saw the miserable villages which were all that remained of the once powerful Songhay Empire, ruined by the attacks of Moors, Tuareg, and Fulah. The interest aroused by Barth's discovery that the Benué so closely approached Lake Chad resulted in a government survey of the possibilities of navigation of the river. Major Laird was in charge, and 340 miles were accurately charted.

Royal Society, June 2—C U Ariens Kappers. Some correlations between the brain and the skull (David Ferrier lecture). While the brain-case generally adapts itself to the form and growth of the brain, the author begins by giving some examples in which a one-sided external compression (Teleostomes) or a more general space economy in the neurocranium (birds) seems to be the primary factor in determining some external (and internal) morphological features of the brain. He then discusses the brain and skull shape in mammals in relation to bodily characteristics and intrinsic changes in the brain itself, and their influence on the general and fissural aspect of the pallium. Proceeding to the possibility of establishing anthropological differences in the brain, the author discusses the use of certain standard lines, angles, and indices for expressing such differences in figures. He then proceeds to the general and fissural brain morphology of races in which, in addition to other features, the height index of the skull differs a good deal, and he compares the brachy-hypsicephalic Armenian with platy-brachycephalic Northern Mongol and the latter with meso- or subbrachy-hypsicephalic Chinese brain. Further, the Chinese brain is compared with the Japanese brain. The very limited possibility of using the same standard lines for endocranial casts of extinct races is discussed. The brain (endocranial cast) of Dubois' *Pithecanthropus erectus* is compared with the chimpanzee's and orang utan's. Then follows a discussion of the frontal region in recent man, especially Negro races, and the fissural changes in this region in connexion with cytotoxic and functional fields, chiefly in the vicinity of the mid-frontal. The phenomena observed in fissural development in general are briefly discussed. With the anthropological differences in the brain, which doubtless occur, we should try to differentiate between brain variations primarily depending on, or at least correlated with, the skull and intrinsic changes in the brain.

Optical Society, May 12—J W Perry. The  $F/1.8$  quartz monochromator-spectrograph. The circumstances in which large monochromators and spectrographs of especially high illuminating power are requisite are discussed, and the dependence of illuminating power and instrument efficiency upon the essential optical characteristics of such instruments is investigated. A description is given of a large instrument fulfilling the combined functions of monochromator and spectrograph, the relative aperture of which varies from  $F/1.6$  at  $0.185 \mu$  to  $F/2.0$  at  $1.2 \mu$ , and records of performance are described.—R F Hanstock. The transmission of light in diffusing media. The transmission of light by thin films of diffusing material is investigated, a flicker photometer being used for this purpose. The intensity  $I$  of the diffuse light transmitted in the direction normal to the surface is related to the film thickness  $x$  by the empirical equation

$$1/I = C(1 + ax + (ax)^2),$$

where  $a$  is a constant depending on the opacity of the material of the film to diffuse light and  $C$  is approximately constant for all substances. The ability of a film to hide a contrasting background is proportional to the quantity  $H = 1/I$ , complete hiding being attained for a value of  $H$  which is constant for a variety of white and coloured paints and papers. An accurate method of measuring the opacity or hiding power of such films is described.

## PARIS

Academy of Sciences, April 25—Gabriel Bertrand and Mme M Rosenblatt. The unequal proportions of manganese in green leaves and etiolated leaves. Green leaves are richer in manganese than etiolated leaves.—R Fosse, P De Graeve, and P E Thomas. A new plant principle: uric acid. Uric acid has been extracted from various seeds (especially from *Mehlotus officinalis*). It was identified by its crystalline form, by elementary analysis, and its reactions.—Andre Blondel. A new algebraical representation of alternating currents and of other oscillatory phenomena. The notation suggested facilitates rapidity of calculations and their physical interpretation in the applications of electricity and other oscillatory phenomena.—Louis Roy. The elastic line in the fundamental equations of the resistance of materials.—E Kogbetliantz. The developments of Laguerre.—C E Winn. The convergence of a series derived from another series with limited variation.—Arnaud Denjoy. The continuity of singular analytical functions.—Michel Fekete. The number of changes of sign of a function in an interval and its moments.—de Seguer. The classes of substitutions of order 2 of linear, quadratic, Hermitian, and left groups in a Galois field of odd order.—N Moukhelekhvili. The problem of torsion of compound elastic beams.—V Smirnov and S Soboloff. The plane problem of elastic vibrations.—B Galerkin. The equilibrium of a thick circular plate in the form of a circular sector.—Alfred Rosenblatt. The stability of the Couette movements of viscous liquids.—R Swyngedauw. The rational calculation of pulley belts.—R Wavre. The extension of a theorem of Stokes relating to fluid stars.—D Belorizky. The radius of convergence of the series in the problem of two bodies, treated by Levi-Civita's method.—P Guntini. The distribution of the residual velocities of  $B$ -type stars.—J Dufay. The energy curve of the star  $P$  Cygni. The energy curve of this star is not that of a black body.—Ch H Muntz. The resolution of the dynamical problem of elasticity.—Marcel Mennesson. A method of measuring lengths and thicknesses with high precision. Air under constant pressure flows through an orifice the section of which is a function of the length to be measured. The volume of air passed is determined by reading a length on a water manometer. A change of length of  $0.01 \text{ mm}$  is thus amplified to  $500 \text{ mm}$  on the manometer.—Pierre Vernotte. The measurement of the thermal conductivity of bad conductors: the calorimeter method.—Leon Grillet. The electrical conductivity of black paper. Applications.—M Pauthenier and P Delahaye. The electrostriction of benzene.—Charles Dietsch. A method of measuring high intensities of continuous current.—R Chevallier. The magnetisation of macroscopic powders in weak fields.—R Freymann. The absorption spectra of ethylene and benzene derivatives in the infra-red.—J Rabinovitch. The rotatory dispersions of benzene solutions of  $d$ - $\alpha$ -pinene and  $l$ - $\beta$ -pinene. Correction to a preceding note.—Horia Hulubei. Contribution to the study of the Raman spectrum of water.—H Buisson, C Jausseran, and P Rouard. The transparency of the lower atmosphere.—Mlle Y Cauchois. The spectrography of the X-rays by the transmission of a non-canalised pencil through a curved crystal.—Georges Fournier. The composition of atomic nuclei.—H Barjot. The rational utilisation of solar heat.—D Skobelzyn. The spectrum of the  $\gamma$ -rays derived from thorium.—Miles C Chamie and A Korvezee. Centrifuging alkaline solutions of polonium.—Pierre Montagne. The formation of acetylene, starting with methane at low pressure, under the influence of condensed sparks. A study of the conditions (pressure of methane, capacity of condensers) giving the highest

yield of acetylene according to the equation  $2\text{CH}_4 = \text{C}_2\text{H}_2 + 3\text{H}_2$ —H Figour and P Jacquet Comparison of the electrolytic deposits of zinc and cadmium from the point of view of the protection of steel against corrosion Zinc deposited from a sulphate bath is less resistant to corrosion than that deposited from a cyanide bath The method of testing for corrosion is not a matter of indifference Thus in a salt fog or in a wet warm atmosphere, cadmium protects steel better than zinc, but in outside air zinc is more resistant—Georges Allard The influence of substitutions on the frequencies of organic bodies—Ch Zinzadze The preparation of trimagnesium phosphate—B Bogitch The principles of the treatment of nickel minerals—L Palfray, S Sabetay, and Mlle Denise Sontag A method of determining aldehydes based on the reactions of Cannizzaro and of Claisen The method is based on the reaction

On account of its high boiling point, benzyl alcohol is used as the solvent for the potash The aromatic aldehydes have been proved to react quantitatively in the sense of the above equation—M Battegay and L Deniville The chlorides of the arylsulphuric acids,  $\text{ArO SO}_2\text{Cl}$ —P Mognaud The method of determining fluorine—Jacques Duche The action of ether and chloroform on the Actinomyces of the asteroid group—R J Gautheret The production of chlorophyll in roots exposed to light, especially in the root of barley—Pierre Chouard and Georges Teissier Relations between the growth of various parts of melon seedlings and the quantity of reserves left at the disposition of the embryo—Charles Perez The small sexual differences of cuticular ornamentation in *Eupagurus*—P Vignon The morphological explanation of the wings in the Diptera and Coleoptera—A Back and R Legendre The sexual state of *Germo alalonga* during the fishing season—Mlle Anne Raffy The variations of dissolved oxygen consumption during the death of marine stenohaline fishes passing from fresh water to sea water—Raoul M May The lasting action, as a substitute, of the intraocular graft of the thyroid from a newly born rat on the development of a white rat the thyroid of which had been removed—A Radoeff Researches on the stimulation of growth and of metabolism in the tissues of wheat The acceleration of growth produced by a preliminary treatment of seeds with solutions of salts of certain metals (manganese, magnesium, zinc) has been proved (Popoff, Bertrand, Brenchley) Experiments on the metabolism of plants stimulated in this way confirmed the increase in growth, but gave negative results for increased metabolism—Raymond-Hamet The sympatholytic poisons The possibility of transforming, by a vaso-dilative action, the vaso-constrictive action of those amines not inverting the hypertensive action

#### VIENNA

Academy of Sciences, Feb 11—Franz Ackerl Force of gravity at the geoid—Josef Norbert Dorr The migration of birds and moonlight In many cases it is difficult to observe any dependence of the times of the spring and autumn flights of birds on the meteorological conditions Observations made over a long series of years in Austria, Hungary, France, Switzerland, etc., show that the main flights of those birds which are mainly night-migrants occur during the periods favoured by moonlight—Fritz Wessely and Franz Lechner 1 2 3 4-tetrahydroxybenzene derivatives Synthesis of 6 7 8-trihydroxycoumarin and of dimethylfraxetin An improved method of preparing 1 2 3 4-tetrahydroxybenzene, and also its conversion into 6 7 8-trihydroxycoumarin and

dimethylfraxetin, are described—Leopold Schmid and Richard Huber Colouring matter of *Papaver rhoeas*—Carl Wirtz Photometric observations with the great (67 cm) refractor of the observatory at the University of Vienna The observations described were made mostly on Saturn's system—Joseph B Niederl The structure of acetone-cresol condensation products—Heribert Grubitsch The processes occurring during the galvanising of iron—Wolfgang Grobner Minimal bases for the invariant bodies of cyclic and metacyclic permutation groups—Eberhard Geyer Short account of the anthropological results of the Lappland expedition of 1913–14 supported by the Vienna Academy of Sciences The measurements made and the photographs taken during this expedition indicate mixing of the Lapps with their Scandinavian neighbours and with Asiatic (North Siberian) tribes

Feb 18—Norbert Lichtenacker Geomorphological investigations in the French Alps. A survey is given of the geological development of the French Alps—Franz Lippay Contraction of skeletal muscle during deficient formation of lactic acid The large quantities of lactic acid regularly appearing during the permanent contraction of striped muscle are by some considered to bear a causal relationship to such contraction The author's experimental results show that this is not the case, although the course of the contraction may be influenced by the lactic acid, the sense of such influence is, however, not the same with muscle contracted by means of chloroform as with muscle contracted by heat—Franz Werner Results of a zoological expedition to Morocco in 1930 (4) Orthoptera More than ninety Moroccan species, ten of them not previously described, are discussed The main work of the expedition consisted in revision of the Moroccan species from various difficult genera, such as *Hololampra*, *Pyrgomorpha*, *Acinipe*, and *Eurypteryphes* A number of species were found on the Great Atlas Mountains at a height of more than 2500 metres—Oswald Richter New contributions to photosynthesis and photolysis, principally in living plants By means of the so-called 'artificial high sun' (made by Messrs Heraeus of Hanau), which furnishes extraordinarily intense ultra-violet rays, particularly those of wave-length below  $300\mu$ , a number of the effects of such rays have been studied These include, for example, the decomposition of chlorophyll—which is easily effected in leaves of *Tropaeolum majus*, *Robinia pseudacacia*, and *Iris florentina*—the hydrolysis of starch, the decomposition of anthocyan, necrosis colorations, etc

### Forthcoming Events

#### FRIDAY, JUNE 10

ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Meeting), at 4—Dr Fortes and others Discussion on Cultural Stages

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section) (Annual General Meeting), at 5—E Clarke Tay's Choroiditis

ROYAL SOCIETY OF MEDICINE (Laryngology and Otology Sections) (at Eye and Ear Hospital, Portsmouth)—Summer Meeting (continued on June 11)

#### MONDAY, JUNE 13

MIDDLESEX HOSPITAL MEDICAL SCHOOL, at 5—Dr A T Wilson The Physiology of the Adrenal Gland (Succeeding Lecture on June 16)

#### TUESDAY, JUNE 14

LONDON HOSPITAL MEDICAL COLLEGE, at 5 15—Dr J R Marrack The Structure of Molecules in Relation to

- Biology and Medicine (*Succeeding Lectures on June 16, 21, 23, 28, and 30*)  
 EUGENICS SOCIETY (at Linnean Society), at 5 30—Dr A S Paterson The Law of Anticipation in Mental Disease  
 INSTITUTION OF PETROLEUM TECHNOLOGISTS (Special Summer Meeting) (at Royal Society of Arts), at 5 30

## WEDNESDAY, JUNE 15

- RESEARCH DEFENCE SOCIETY (Annual General Meeting) (at London School of Hygiene and Tropical Medicine), at 3—Sir Arthur Keith Some Aspects of the Modern Conflict between Reason and Sentiment (Stephen Paget Memorial Lecture)  
 INSTITUTION OF MINING ENGINEERS (Summer Meeting) (at Sheffield) (*continued on June 16 and 17*)  
 ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY (at Northampton Polytechnic Institute)—Annual Election of Committee and Officers

## THURSDAY, JUNE 16

- ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (Annual General Meeting) (at Manson House, 26 Portland Place, W 1), at 8—At 8 15—Col S P James, Prof W Schulemann, Prof N H Swellengrebel, Dr C A Henry, and others Discussion on Synthetic Anti-Malarial Preparations and Quinine

## FRIDAY, JUNE 17

- PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5—Prof Max Planck The Concept of Causality in Physics (Guthrie Lecture)  
 ILLUMINATING ENGINEERING SOCIETY (Annual General Meeting) (at Royal Society of Arts), at 7 15—Sir Francis Goodenough Presidential Address

JUNE 16 TO 18

- ANNUAL COLLOID SYMPOSIUM (at Ottawa, Canada)

## Co-operation in Medical and Agricultural Research

AT a meeting of the New Zealand Branch of the British Medical Association held in March last, a resolution was approved urging the necessity for further research regarding the "factors which govern the incidence of goitre, in particular its relationship to the nature of the soil and the food of the people", and recommending that arrangements should be made to co-ordinate medical research with soil and animal research

Goitre, which occurs in both human beings and animals, is an endemic disease which appears to be correlated with the nature of the soil and, according to most observers, with the iodine content of the food. A great deal of research has already been done, especially in Switzerland, the United States of America, and in India, but the problem of the etiology of the disease and the best means of its prevention are by no means completely solved. The resolution to co-ordinate work on soils, domestic animals, and human beings is undoubtedly sound.

Investigations on these lines have been carried out in Great Britain in recent years. The greatest obstacle to progress is the difficulty of determining with accuracy the amounts of iodine present in soils and foodstuffs. A committee of the Medical Research Council, with the assistance of Sir Robert Robertson, of the Government Chemical Laboratory, is at present trying to evolve a method which will give trustworthy data and can be used as a standard method throughout the world. If such a method be found, the advance in our knowledge will certainly be along the lines suggested by the New Zealand Medical Conference. It is probable that through the Imperial Agricultural Bureaux, the Medical Research Council, the Public Health Departments, and the Agricultural Research Council, co-operative research not only between medical, veterinary, and agricultural research workers, but also between institutions in different parts of the Empire, may be arranged. It is by such co-operative work that the goitre problem is most likely to be solved.

That such co-operation should not be limited to the question of goitre is emphasised by a message from Lord Bledisloe, the Governor-General, to the New Zealand medical conference. Lord Bledisloe has, for many years, shown a deep interest in veterinary and agricultural research, and in his message he directs attention to the interrelation of human and animal food deficiency diseases. He refers specially to diseases "traceable to lack of

iron, calcium, iodine, phosphates, vitamins, or other essential food factors", and points out that these diseases, which have a common etiology in both human beings and farm animals, require further investigation

A number of deficiency diseases, for example, Waihi disease in cattle due to phosphorus deficiency, bush sickness to iron deficiency, goitre believed to be associated with iodine deficiency, and several diseases in sheep which may be due to lack of either calcium or phosphorus or both, are already being successfully investigated in New Zealand. There is evidence that similar mineral deficiencies occur under certain conditions in the food of human beings, and there is no doubt that lack of some of the vitamins is of common occurrence in large sections of the world's population

The wealth of knowledge which research in nutrition has accumulated in the past few years, perhaps on account of its very newness, has not yet been fully applied to the prevention of disease in human beings and domestic animals. The lead given by Lord Bledisloe for the combination of medical, veterinary, and agricultural research resources for an attack on diseases the incidence of which is influenced directly or indirectly by nutrition is therefore timely, and deserves the attention of those responsible for the direction of medical and agricultural research in other countries as well as in New Zealand

### Towards a New World Order

FOR some years before the present trade slump and the economic crisis of last year, acute observers had perceived the bankruptcy of many

accepted political and economic theories and the inadequacy of the administration in most western countries to deal with these problems with which the accelerated application of scientific discoveries and methods in all fields of industry and of society was confronting them. The War itself was only a revelation of this bankruptcy and inadequacy in regard to national defence and security, and the halting progress towards disarmament during the last fourteen years underlines that failure. To an unprejudiced observer, the governments of the world as a whole appear to have "learnt nothing, forgotten everything"

The present critical position must be largely attributed to the failure of those in authority to perceive the fundamental changes which have occurred during the last fifty years in the whole character of industry and society, despite repeated warnings. We can recall no more lucid exposition of the fundamental change in human relations for which applied science has been responsible than Prof J T Shotwell gives in an admirable introductory chapter to his book on the Kellogg Pact, but the indifference of the politician and even of industry to such warnings suggests something more deliberate than neglect. The volumes under review have this in common, that from different angles they present an invaluable and constructive analysis of the underlying causes of our difficulties and supply the outline of what to most sane and disinterested persons will appear to be a reasonable solution, and one that in its emphasis on facts and freedom from prejudice or preconceived ideas should command the earnest consideration of all scientific workers

(1) "Letters to John Bull and Others" is a popular and spirited exposition of the idea of an International Police Force so ably expounded by Major David Davies at greater length in the "Problem of the Twentieth Century". This restatement of the essential points is exceedingly timely and should promote a wider understanding of the problems confronting the Disarmament Conference. "Robert the Peeler", in entertaining but convincing manner, contrives to lay bare the fundamental principles of real progress. The new weapons which science has forged have made disarmament and the renunciation of war the only alternative to annihilation, but he goes further and suggests that by co-operation in an International Police Force the new weapons can be used for the mutual protection of all countries, science having created the conditions which make it possible to supply to the modern world the prin-

ciples and methods successfully practised centuries ago by the Greeks

The very extent to which the new weapons dominate warfare makes it possible to contemplate handing them over to a small international authority and force which would consequently have a striking power out of all proportion to its numbers and, under modern conditions of transport, could take rapid and effective action in any part of the world "Robert the Peeler" visualises this International Police Force in conjunction with an International Court of Justice and a tribunal to enforce the findings of which it would be primarily organised

Naturally, in a short popular work of this type, only the briefest outline can be given of the method of organising such a court or police force, but it is all to the good that as many people as possible should be induced to view the problem as a whole and consider impartially the idea of an International Police Force Apart from anything else, the existence of such a police force would eliminate decisively one of the gravest present dangers when no adequate defence is available against, for example, air attack, the temptation to get one's blow in first Nor does "Robert the Peeler" fail to note the folly and danger to society of allowing the continuance of vested interests in the manufacture and exploitation of the new weapons of war

(2) To destroy the underlying causes of war, by constructing channels of international co-operation and by creating a disinterested point of view wherever national interests conflict is, however, as Mr Greaves points out, vastly more important than declaring war the evil everyone knows it to be Disarmament is after all a negative aspect of the League, and one great merit of Mr Greaves's book is that it gives a connected account and a lucid analysis of the growth of the technical and administrative work of the League in its various expert committees and commissions and assesses their contribution towards the building of a new world order

The tendency for international organisation to extend is one of the most significant of modern times, and one which received further impetus during the War as indicated in the various inter-Allied systems for shipping control, food, and purchases The parallel tendency for government to rely increasingly on smaller and more specialised groups of men is equally striking and is changing the very nature of politics Government has become a thing impossible without the advice of experts and the schemes of technicians, upon whom

almost daily are thrust new and weighty functions The consequent danger of the legislature becoming the tool of its expert advisers is one to which in Great Britain Lord Hewart has directed attention, and the recent Committee of Inquiry, while recognising the tendency, did not regard it as fundamentally wrong but merely recommended the institution of certain safeguards

The more marked technicality of administration and the necessity for expert opinion are also supported by the need for securing the agreement of the organised and articulate interests affected in State action The outcome is seen in the practice of creating advisory committees of experts representing outside interests which act as permanent consultative bodies at the disposal of the government Accordingly, the functional representation of industry, upon the need for which under our new tariff policy Capt H Macmillan has rightly insisted, is only a process of devolution which is taking place to an increasing extent and reflects a further development of the basic principle of self-government

These three tendencies give special significance to the League's expert committees The growing number of questions which can only be solved by international co-operation, the increasing authority of the expert, and the advance towards functional self-government, stress the importance of these international committees, and this critical study of their development is at pains to elucidate the various factors which have contributed to their relative success or failure Designed in the main to be consultative, they have already achieved more than a mere advisory function, and although their members are appointed invariably in theory and usually in practice on technical qualifications, the fact that they are constantly in touch with their governments, although not government representatives, has enabled them to transform national into international administration with notable measure of success The most significant fact about these committees is, however, that each committee deals with its particular problems from a non-national point of view, exactly in the way visualised by General Smuts in his Sidgwick Memorial lecture when pleading for the scientific spirit in human affairs, especially in the international sphere

It should be unnecessary to stress this point further in view of the events of the past year, but the brief review of the activities of these committees which Mr Greaves gives us demonstrates plainly that their greatest successes, such as the reconstruction

schemes for Austria, Hungary, and the Greek refugees, are to be attributed to the greater urge which an aroused public opinion and the responsibility for a definite and urgent attack supplied. Equally it is true that in the lesser known but valuable work of the Health Committee, the Economic Committee, the Mandates Commission, or the Communications or Transit Committee, there can be found abundant evidence of the fruitfulness of this new method of handling difficult technical international questions, and that agreement and co-operation are not difficult to secure provided that the duty of securing it is entrusted to specialists more interested in their subject than in national politics or prestige.

While we have already the machinery for handling such questions in this way, which by its very operation co-ordinates technical organisation and develops habits of co-operation and mutual confidence as well as facilitating the growth of a world point of view upon the needs of a world society, the success of the method is largely proportional to the extent to which the personnel of the committee is disinterested. Members must be nominated not as representatives of their countries but as individuals and for their expert qualifications. The necessary influence and contact with the governments of their countries is best secured when their expert qualifications are combined with high personal standing not only professionally but also in the world of government departments. If the expert committee is marked out as a most helpful line of advance towards a new world order in which civilisation will gain control over the destructive forces released in the last fifty years, success can never be achieved until, on one hand, scientific workers are increasingly disposed to accept the social and political responsibilities which are now rightly theirs, and on the other hand, there is, in Great Britain at all events, a much greater readiness to admit the scientific worker to administrative posts on equal terms with experts drawn from other spheres.

The book deserves and demands attention from scientific workers in particular, for the problems which call for treatment in this way are increasing and urgent, and failure to solve them to-day makes solution or control no easier to-morrow. Scientific workers cannot evade their responsibilities for sharing in this task of shaping international government and, by securing a wider publicity for this type of administration, assisting the growth of the public opinion which will promote its success in the more difficult fields of disarmament or

treatment of minorities where political factors still prevent progress.

(3) In "The Economic Consequences of Power Production" Mr Fred Henderson contributes an able analysis of the effect of the immense increase in our productive powers which has resulted from the application of science to methods of production, particularly in relation to the distribution of wealth. The effect of science on production has been discussed largely as if it were a matter of efficiency of production alone, and its effects on distribution have commonly been disregarded or overlooked. This has been partly due to the fact that until recent years the existence of outside markets has tended to mask the full effect of what has really been a fundamental change produced by science in our methods of production. It is only in the last few years, as these outside markets have tended rapidly to disappear and in the Far East and elsewhere countries which were formerly consumers only have entered the ranks of producers and erected barriers against the entry of the goods produced elsewhere, that the resulting dislocation of trade and unemployment culminating in the present depression have forced us to realise the existence of maladjustment and the startling contrast between our success in effective production and our failure in distribution.

To the demonstration of this change and its mechanism Mr Henderson devotes the first and most lucid part of his book. What science has given us in the mechanical developments of the last half-century is not merely more production but also a new kind of production. A profound and vital change has taken place in the relation of human labour to the processes and products of the world's work. Human physical energy has been superseded by other and greater propellent powers. The human service associated with the machine has ceased to be labour in the old sense. It is now mainly a matter of admitting power to the machine and regulating its degree and direction. It is labour on a higher level of general intelligence than the old unskilled manual labour, and carries a greater strain of responsibility, but in intelligence and responsibility it has nothing in common with skilled craftsmanship. Accordingly, the technique of an industry and intimate knowledge of its processes, raw materials, and products tend to become concentrated in a small central staff of experts. Output in production has thus now only escaped from the limitations of physical energy, but skill has become so unimportant in many industries that the low-paid labour from

rural districts of Japan, China, or India can compete in all essential respects with experienced European operatives

This shifting of the function of measuring output from labour to non-human energies is the main factor responsible, through our failure to adjust our distributive system, for the present confusion. Every means by which, through rationalisation or fresh scientific discoveries or inventions, our efficiency or resources of power production are increased, decreases the volume of labour required to produce a given output, or, in other words, renders human labour obsolete. Now that previous-customer communities have equipped themselves in the same way for supplying their own industrial products and are protecting their home markets against the incursion of such products from outside, while simultaneously seeking outside markets for themselves, we are rapidly approaching a position in which the home market of every industrial country is unable to absorb the equivalent of its own output and finds the rest of the world closed against the surplus. Widespread and increasing unemployment is the result, and this position, in the midst of incredible abundance which the escape of production from the limits of human labour has made possible, is a grave indictment against our present distributive machinery.

Thus far Mr Henderson can scarcely fail to carry his readers with him. In the second part of the book he does not reach the same level in analysing the defects of our distributive system, nor does the book include anything more than the broadest constructive suggestions. None the less the main theme is incontestable. The fundamental change which science has made in our methods of production demands certain changes in the economy of distribution. The latter can no longer be allowed to remain on its pre-scientific age basis, and the extension of scientific method and planning into this field is long overdue. We have to face the creation of a new social order for making effective the release of mankind into an age of more abundant living, and the social control of production scientifically planned in relation to use and consumption up to the level of human needs affords the only basis for such a new order.

Mr Henderson, in directing attention to the profound changes involved by the new conditions of power production and by challenging frankly some of the assumptions in regard to costs of production, and the distribution of leisure and profits which are often too lightly made, renders a

notable service. "Man does not exist to serve the needs of an economic system", he rightly observes, and in the creation of the new social order the application of scientific methods and the impartial spirit of science to the solution of our social and economic problems may play a decisive part. We cannot return to the inefficient or wasteful methods of production of the past, but science must do more than merely increase efficiency of production. At least it is clear that no policy of muddling timidity or prejudice will meet the situation.

(4) "The Riddle of Rationalisation" is a much slighter study than Mr Henderson has given us, but in spite of the omission of any reference to the change in the position of labour in our industrial system produced by machine or power production, Major Barley gives a very competent review of the possibilities of the scientific reorganisation of industry from an industrial point of view. Without challenging, as Mr. Henderson has done, the basic principle of capital or private ownership upon which our present production system rests, he equally recognises that the rationalisation of industry and its scientific management, by increasing the efficiency of production, inevitably reduce the labour required for the same output and thus promote unemployment. Recognising that a return to pre-scientific and inefficient means of production is out of the question, Major Barley sees the solution in the planning of production to increase the standard of living, and the distribution of wealth proportionately with the increase in the efficiency of production resulting from the application of scientific methods or discoveries.

Probably some distribution of leisure may be simultaneously required, but the plea for the extension of scientific methods to the economic field, for constituting an accurate industrial science for the service of the community and for planning production and distribution so far as possible in relation to our known needs, cannot be ignored. A national plan makes scientific adjustment possible and may offer some prospect of solving the unemployment problem and increasing the standard of living of the whole community by fifty per cent, provided the plan is conceived on wide enough lines and appropriate international co-operation secures an adequate and unprejudiced treatment of such matters as reparations and war debts, tariffs, and the international price-level and credit system.

These are large assumptions, but not so large as the pessimistic assumption that science has nothing further to contribute or that its guidance will not

enable man to find a way to the control of those forces which the careless application of scientific discoveries and principles in the mechanical world has released. That simultaneously with increased efficiency of production there has been a perceptible though disproportionate increase in the general standard of living is at least of hopeful significance, and until national planning has been attempted on the lines Major Barley suggests, we remain without an answer to the questions whether it is possible to raise the standard of living and simultaneously to reduce unemployment to the required extent.

The concrete suggestion of a commission for individual industries under an expert National Advisory Economic Planning Department is similar to that since proposed by Capt Macmillan under the Tariff Commission, and, like that, is essentially an attempt to determine whether, without radical changes in the nature of society, it may not be possible to organise on scientific lines the production, distribution, and exchange of goods so that the needs of the whole community may be adequately served.

#### Plant Chemistry

*The Glycosides* By Dr E F Armstrong and K F Armstrong (Monographs on Biochemistry) Pp vii + 123 (London, New York and Toronto Longmans, Green and Co, Ltd, 1931) 12s 6d net

THIS healthy bud from a vigorous parent chronicles important advances in plant chemistry. A chapter in the senior author's earlier monograph, "The Simple Carbohydrates and the Glucosides", published in 1910, was called "The Natural and Synthetic Glucosides" and occupied 14 pages. This has now been expanded into the new volume, which fills 110 pages, exclusive of bibliography and indexes. The change of spelling from "glucosides" to "glycosides" is made in accordance with official practice, and is a recognition of the fact—apparently not realised in 1910—that sugars other than glucose take part in forming these characteristic plant condensation products.

Several hundred of these substances have now been identified. Many are of a very complex nature, and their investigation is correspondingly difficult. The nature of the sugar itself has to be established, it is in most cases one or another of the modifications of glucose, though benzoyl-glucose, primverose, vicianose, digitoxose, digitalose, and rhamnose have all been isolated from natural glycosides,

as have several disaccharides and trisaccharides. The non-sugar part of the molecule may belong to any of an unusually wide range of compounds—phenols, coumarins, anthoxanthins, anthocyanins, isothiocyanates, and many others, including some the structure of which has not yet been worked out. The term "aglucone" for these constituents of glycosides seems a little illogical, surely it should have been "aglycone".

From the last two chapters of the book it is clear that the precise rôle of glycosides in plant physiology still awaits elucidation from the further intensive research that is certain to be undertaken, if only for the reason that a number have definite and recognised pharmacological action, among the better known of these are the glycosides of digitalis and strophanthus.

The volume is as well produced as others in this series, though there are some minor printing errors. Little attention has been paid to uniformity in the lay-out of the tables, Tables 1, 3, and 6 are arranged on one principle, Table 2 on another, Tables 4 and 5 on another, and neither Table 2 nor Table 5 has any column headings at all. Type and paper are adequate, but the luxurious effect of the transverse gold lettering replacing the old vertical black type on the spine is rather marred by its relative illegibility and bad centring. A L BACHARACH

#### Principles of Modern Physics

*Modern Physics - a General Survey of its Principles*

By Rev. Theodor Wulf. Translated from the second German edition by C J Smith. Pp. xi + 469 (London Methuen and Co, Ltd, 1930) 35s net

THE sixth-form scholar and the first-year university student are in these days well catered for in the matter of textbooks of physics. To be sure, these in general conform to a standard pattern which lends itself to a grasp of detailed facts classified in a traditional and natural manner and to the requirements of examination tests. There has been a tendency, however, of late years to break away somewhat from this pattern, and the book under review constitutes a very notable departure indeed from accepted models. Assuming the "essential and final goal of Physics" to be "the derivation of phenomena on the basis of the internal structure of the smallest constituent particles of matter", the author states that his aim is to give a "co-ordinated account of the fundamental results of Physics". In consequence, he collects in a first part the facts about the material world.

which are concerned with movements of observable bodies, transmission of waves, gravitation, and the elastic properties of matter, and then proceeds to Part II, which opens with a chapter on the history of the atomic conception and the discovery of the chemical elements and their classification

Part II treats the states of aggregation, heat, and thermodynamics, with a discussion of the facts which help to the comprehension of the atomic hypothesis. From the concept of the simple atom, the author passes on in Part III to the phenomena of electricity and magnetism, utilising these to develop the idea of an atom with a structure, thus leading to the hypothesis of electrons and nuclei and the part which they play in the emission and absorption of energy by matter. Here will be found an elementary account of the Planck theory of full radiation, Bohr's theory of the emission of spectra, and generalities about the quantum hypothesis. To complete the picture of the physical world, there follows Part IV on the "Physics of the Ether", embracing a discussion of the phenomena of light and radiation in general, and leading to a short account of Einstein's theory.

It is a commonplace criticism of our system of scientific education to blame it for the production of students crammed with facts the significance and relationships of which they fail to comprehend. We are of the opinion that this is a criticism which overstates the seriousness of the situation, but in so far as it may be true, we can conceive of no better antidote to the so-called deadening effect of the customary textbook than to introduce the young student to this work. It gives a clear picture of the physical world, as consistent with our knowledge as is possible at present, and presents it as a model still incomplete, involving difficulties, and destined no doubt to be profoundly modified in the future. For this inculcation of a truly scientific and philosophic outlook the book is worthy of high praise and can be heartily recommended to sixth-form boy, university student, engineer, medical teacher—indeed, to anyone who may have, for one reason or another, acquired some knowledge of the physical sciences and desires to obtain an insight into their realm, and an understanding of the great changes which have taken place there of late and what effects these changes have produced on the traditional conceptions of space, time, and matter.

The translation appears to have been well done, and shows none of the stiffness of style which accompanies a too literal rendering of a foreign work.

No. 3268, Vol. 129]

## Short Reviews

*Les Coaptations chez les insectes* Par Dr Jean Corset (Suppléments au Bulletin biologique de France et de Belgique, Supplément 13) Pp 337 + 2 pls (Paris Laboratoire d'Évolution des Êtres organisés, Les Presses universitaires de France, 1931) 85 francs

IN his introduction to this treatise, the author explains the origin and significance of the term 'coaptation'. He applies it in the sense adopted by M. Cuénot with reference to Arthropoda, and especially insects. A coaptation is defined as a reciprocal adjustment of two independent parts which perform, as the result of their union, a definite function. Examples of such devices are particularly numerous and well developed in connexion with integumentary parts or organs among insects, especially in the order Coleoptera.

M. Corset's memoir is divided into four parts, and in Part I he describes the anatomical features of coaptations as exhibited among diverse groups of insects. Special mention may be made of the interlocking mechanism of the ovipositor valves in Orthoptera, the elaborate articulatory devices in relation with the wing covers and thorax of Coleoptera and some Hemiptera, sutural interlocking of coleopterous elytra, various types of fore and hind wing union, and so on. Part II is concerned with the functional aspects of the subject, and, in this connexion, the puzzling problem of the curious mechanical perfection of parts, often in relation to their apparent feeble utility, is raised. In Part III the biological rôle of these various devices and mechanisms comes in for treatment. Of especial interest are the examples of their close convergence in structural detail among members of very different families and orders that are brought to notice.

Part IV. is more or less philosophical in scope and is devoted to evolutionary questions associated with the parts in question. This subject is rather fully discussed, and it appears to the author to demonstrate the adaptation of a means towards an end through the operation of a directive force or agency. The memoir is well illustrated, mostly by means of sections of the parts involved. It is, on the whole, a very readable work that is suggestive in its outlook. Its production, it may be added, has involved a good deal of original investigation into the structure of the various devices that are discussed.

A. D. IMMS

*An Introduction to Plant Physiology* By Dr W. O. James Pp viii + 260. (Oxford Clarendon Press, London Oxford University Press, 1931) 7s 6d net

PLANT physiology has few literary champions. There is not one comprehensive textbook on the subject suitable for students reading for a final degree in botany in Great Britain. Except where a junior university course such as that of First M.B. or intermediate science is actually given round a prescribed book (not a commendable practice), there is no botany textbook of that status which gives physiology a fair hearing.

Now we have the reverse. Although the author of this book disclaims the fulfilment of requirements of any formal syllabus, the subject matter dealt with is of the standard 'prescribed' for first-year university students, but whether such students are prepared to invest in a textbook specially for the physiology section is a different matter.

The science of plant physiology is still in the melting pot of hypothesis and conjecture, perhaps more so than any other science. Yet, Dr James has avoided most of the controversial matter, still keeping his subject alive and to the point. The order of topics is somewhat revolutionary, and thus, we believe, the value of the book is enhanced. Photosynthesis is considered very early in the book, whereas growth and germination are relegated to the end. Nitrogen metabolism receives much deeper consideration than hitherto, and the various forms of plant irritability are dealt with fairly, more after the Continental style than the British, which scarcely considered the subject at all.

The method of treatment is good and the style is excellent. The text throughout is well illustrated. A special feature is the detailed descriptions of experimental work, for, as the author says, "the success or otherwise of an experiment depends so often upon apparent trifles." One of the many details we note with enthusiasm is the discriminating treatment of the important phenomenon of permeability.

*Archæology of the Arkansas River Valley*. By W. K. Moorehead. With Supplementary Papers on *The Prehistoric Cultures of Oklahoma*, by J. B. Thoburn, and *The Exploration of Jacobs Cavern*, by C. Peabody. (Published for the Department of Archæology, Phillips Academy, Andover, Massachusetts.) Pp. x + 205. (New Haven. Yale University Press, London. Oxford University Press, 1931.) 18s. net.

In this volume Mr. Warren K. Moorehead records the results of a comprehensive survey of the archæology of the Arkansas River valley from its junction with the Mississippi near the Louisiana border to its upper waters. The archæological interest of the valley lies especially in the variety of its cultures. These reflect the geographical conditions, which range from the wooded lowlands at the mouth, where are found mound-builders of characteristic 'pottery-belt' type, to the 'buffalo country' with prehistoric settlements, which point to a more settled habit among Plains Indians before the introduction of the horse, and the desert area in which the river takes its rise. The Ozark Bluff-Dwellers, who have been described by Harrington, are within easy reach of the river, and there is an extension of Pueblo culture in western Kansas, probably a migration from Pecos.

The most interesting problem of the area is afforded by what is here called the Texan Panhandle culture of the upper Canadian, Cimarron, Red, and Arkansas rivers, characterised by 'slab-house' construction. Its origin and affinities are obscure. The suggested relation with either Pueblo or Mexican culture gives rise to difficulty from the

absence of features characteristic in these two cultures. Mr. Moorehead discusses the evidence very fully, but in the present state of knowledge there is no possibility of solution. His expectation that the problem will be solved within ten years is probably justified, judging by the progress at present being made in this area. The value of the volume as a contribution to the prehistory of America is much enhanced by the excellent illustrations.

*Digressions of a Man of Science*. By Sir A. Daniel Hall. Pp. 223. (London: Martin Hopkinson, Ltd., 1932.) 7s. 6d. net.

It is sometimes cast in the teeth of the man of science that his interests are narrow and lacking in culture, and that though he has something to say, his literary attainments are not such as to enable him to say it. Both gibes can, no doubt, be supported by examples. The author of these essays is, however, one of many scientific men whose writings make manifest the injustice of the taunts. The range of topics in these "Digressions" is so wide as to cause envy of the versatility of the mind that thinks deeply on philosophical and religious matters, as in "The Faith of a Man of Science" and "Science and Immortality", that can discuss with expert knowledge the economic and political problems of farming ("What Science has done for Farming"), or with equal facility and happy phrase, and with apt quotation from both prose and verse writers in our own and in other languages, handle such diverse subjects as country churches and their mural tablets, the sheep, shingles, and birds of Romney Marsh and Dungeness, the frequenters of auction-rooms, and ideal tulips, to mention a few examples from the twenty-two chapters. Some of the articles have already seen the light in newspapers or magazines, and thanks are due to Sir Daniel Hall for bringing them within the covers of a book. The insertion of the dates on which he penned each article would have added a personal element of much interest.

*Entwicklungsphysiologie der Tiere*. Von Dr. Paul Weiss. (Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe, herausgegeben von Dr. Raphael Ed. Liesegang, Band 22.) Pp. xi + 138. (Dresden und Leipzig: Theodor Steinkopff, 1930.) 11 gold marks.

THIS presentation of border-line problems has no counterpart in the English language. Prof. Weiss has succeeded in bringing together under the title of developmental physiology a survey of the present fluidity imposed by experimental embryology on the older and somewhat effete morphology. This is the best presentation of the post-War change in outlook in biology.

The book deals in particular with the balanced growth of the embryo, organ formation, and the rôle of Spemann's 'organisators'. Growth is analysed in terms of cellular proliferation and cellular differentiation, and the characteristic features of growth *in vitro* and *in vivo* are compared. Metamorphoses and regeneration lead up to a final chapter dealing with recent theories in biology.

The *Dana* Expedition of 1928-1930

ON several occasions reference has been made in *NATURE* to the oceanographical expedition of the *Dana*, 1928-1930. With the support of various Departments of the Danish Government, the East Asiatic Company, and especially of the Carlsberg Foundation, Prof. Johs. Schmidt planned and directed a lengthy cruise in the tropical waters of the Indo-Pacific, to supplement his many years' investigations in the Atlantic and thus to complete the 'magic circle'. The volume now before us \*

is the first ripe fruit. Richly and beautifully illustrated, in clear print, it is professedly a popular account of the voyage with just sufficient leaven of scientific fact and theory to hold one's interest and make a connected story. The illustrations accompanying this article are from the volume.

The voyage began in June 1928 and ended in June 1930. The total distance logged was more than 65,000 nautical miles. The westward route was chosen in preference to the eastward, to take advantage of the prevailing trade-winds and currents of the Pacific. A brief account of the voyage with a chart of the route followed, and the names of the scientific workers and others engaged in the expedition, have already been given in *NATURE* (March 21 and 28, 1931).

The first biological discovery of importance in the Pacific was made between the Marquesas and Tahiti—the larva of a true freshwater eel. Before that, the chief aim of the expedition had been to study the horizontal distribution of the oxygen-free layer of intermediate water, which had been discovered on the first *Dana* Expedition in 1921-1922 and later rediscovered by the *Carnegie* in 1929. According to the hydrographer of the expedition (H. Thomsen) this peculiar phenomenon, unknown in the other great oceans, is due to the lack of vertical movements in the eastern waters of the Pacific. The

oxygen-free layer extends from Panama as far as Tahiti.

The present volume is an extended narrative of the cruise, or rather a series of narratives. It is evident that the members of the scientific staff as well as the leading officers kept a *Dagbog*, and each has been called upon to give his experiences during the voyage. There are twenty contributions in all, and the material has been so skilfully arranged that they dovetail into one another and present a con-

FIG. 1.—Stations in the Atlantic, 1928-1930

tinuous story of the voyage. The different ports and countries visited, excursions on land, the distinctive fauna and flora of the places, customs, costumes, and dances of the natives, earlier history, influence of traders and missionaries and so on, are all described and discussed with deft hands and discerning eyes. Old memories are here revived of Capt. Cook, the *Beagle*, atolls and palolo, tattooing and cannibalism, early Dutch and other adventurers, and especially of the time when the Danes also were pioneers in the discovery of the East.

It would be invidious, where the accomplishment of all is on such a high level, to single out any one of these living pictures for special reference, but an exception must be made in the case of "Christmas in New Zealand", by Fru Ingeborg Schmidt, wife of the leader of the expedition. Instead of appearing out of place in what is essentially a scientific if popularly written work, this account

\* *Dana's Tøgt Omkring Jorden, 1928-1930*. Af Prof. Johannes Schmidt. Pp. 368. (København Gyldendalske Boghandel, 1932) 9 75 kr.

is quite typical of the others. Christmas in the height of summer, a *Thuja* with sparkling lights for Christmas tree, *Risengrød med Mandel*, apple cakes and other Danish *Retter* kept in secret for the festival, visits to the many Danish colonists who have found a second Denmark round Palmerston in the North Island, the reception at Wellington, the wonderful grottoes of Waitomo, with the glow-worms (larvæ of *Boletophila luminosa*) spinning threads and lighting lamps to lure the small insects to destruction, the great forests, ferns and trees, birds and their songs—these and many other notes indicate that Fru Schmidt's journey across the world to meet the expedition at the antipodes was not wasted. The account makes no pretence

The scientific work of the expedition is touched upon in various chapters of this book of the cruise. To understand the references, one must hark back to Prof Schmidt's earlier activities in Atlantic waters. As is well known, after nearly twenty years of persistent search, Johs Schmidt discovered the birthplace of the European freshwater eel in the deepest part of the Atlantic at the western end of the Sargasso Sea. In the present volume, Prof Schmidt shows how his latest exploration of the Mediterranean with improved apparatus has confirmed his earlier conclusions. The *Leptocephali* of the common eel were found in quantities in the narrow Straits of Gibraltar and again in the cul-de-sac at the Straits of Messina, but occurred

only scattered elsewhere and in small numbers, particularly in the eastern basin. This points to an extensive immigration from west to east, similar to that in more northerly waters, and indicates that the eel does not spawn in the Mediterranean.

The eel investigations, however, representing perhaps the cream, count only as a fraction of the immense work accomplished. From North Iceland and the Davis Straits southwards to Brazil, and from the Baltic and Black Sea in the east to the United States and

FIG 2—Distribution of eels of the Indian Ocean

to be other than a simple and faithful picture, yet it gives us a delightful glimpse of life and things in New Zealand.

It need scarcely be added that the expedition was received in all countries and places in the most hospitable manner—by government officials and scientific workers as well as by laymen. At many places indeed the reception was almost embarrassing, as in Samoa, where a native headman insisted upon displaying his family troubles along with his living spouse—by no means a skeleton. The expedition was able, however, to give as well as to receive entertainment. It carried two films descriptive of life and activities in Denmark and the Faroes, and these were shown, with lecture accompaniment, at a number of places in New Zealand, Australia, the Dutch East Indies, and South Africa. This book expresses the gratitude of the members of the expedition for the universal kindness, especially in the British Dominions and Colonies, but one may well believe that, with their soft speech and gentle manner, these Danes would be welcome guests anywhere and everywhere.

Panama in the west, Prof Schmidt and his collaborators have studied methodically the physical, chemical, and biological conditions of the waters from surface to bottom—so methodically that every square of 10° shows a number of stations on it, up to forty in the case of the more important, and the total number of stations has amounted in the course of time to more than twelve hundred. The chart reproduced as Fig 1 epitomises the regional distribution of the investigations. The material collected has been distributed to leading specialists in different countries, and the numerous volumes already published, though the Atlantic series is not yet complete, rival the reports of any other expedition in scientific interest and importance.

By intensive study of the variations, Prof Schmidt has been able to prove that two species of freshwater eels (*Anguilla*), and only two, occur in the Atlantic region, and both resort to about the same place to spawn. This deep part of the Atlantic is some 4000 miles away from Europe, yet the eels of all European countries, from Finland to Greece,

belong to the same race and go to and come from the same spawning region, the *Leptocephali* taking about three years to complete their pelagic wanderings. This remarkable fact, which, one may note incidentally, provides support for Wegener's theory of continental shifting, is in striking contrast to the conditions found in the Indo-Pacific Ocean.

Whereas only one species occurs over the wide expanse of Europe, the islands of the Pacific, for example Tahiti, have three separate species occurring together, and the so-called *Anguilla australis* of earlier zoologists has proved to contain no fewer than four species. In all, the Indian region contains six species (Fig. 2) and the Pacific has about twelve (some being common to both regions). These conclusions, based in the first instance on the adult characters, have now been confirmed by the discovery of the various *Leptocephali*. From the number of species and the conditions found there, Prof. Schmidt has come to the conclusion that the original home of the eels lay in the eastern ocean.

Deep water for, the purpose of spawning, and currents to convey the *Leptocephali* towards land, are apparently necessary for the existence of freshwater eels anywhere. Where one or other is lacking, as in the South Atlantic and on the western side of America, we find no eels in the adjacent countries, and in the Indo-Malayan Archipelago eels are only found in countries and on islands which face directly on to deep water. This is shown in Fig. 3, where the occurrence of eels is indicated by heavy blackening of the coast-lines. The shallow water areas north of Australia and between Borneo, Siam, and Sumatra contain no freshwater eels.

The islands of the Pacific and the coasts of India and East Africa obviously fulfil the requirements, and the *Leptocephali* have not so far to wander. It follows, almost as corollaries, that the Indo-Pacific *Leptocephali* are of smaller size than the Atlantic forms and metamorphose in a shorter time. Yet a remarkable thing is that the adults of several of the eastern species at Tahiti, in New Zealand and in the rivers of East Africa, are of gigantic proportions by comparison with the European and American eels.

No 3268, Vol. 129]

Other discoveries indicate that the tropical regions of the Atlantic and Pacific possess similar communities of eels (deep-water eels, not *Anguilla*), and that their distribution is closely connected with the hydrographical conditions. Thus, *Nessorhamphus ingolfianus* occurs in the transitional regions north and south of the equator, whereas *N. Danae*, with a similar number of vertebrae, occurs only along the equator. Such comparisons of the physical and biological phenomena in the different oceans were among the chief objects of the expedition.

The scientific horizon of Prof. Schmidt is, however, not bounded by the eel. One may recall that

FIG. 3.—Distribution of eels in the Indo-Malayan Archipelago

he began as a botanist and that his field of research, quite apart from his exploratory work, has ranged from floras and the growth of hops to the variations of fish and fowls. This breadth of vision, so clearly displayed in his leadership, is supplemented by exceptional powers of concentration. We can discern both qualities in his review of the conditions in the Mediterranean, his eel investigations there have already been mentioned, his summary of the physical and biological phenomena is of equal significance.

From west to east in the Mediterranean the quantities of phosphates and nitrates, the substrata of organic life, decrease until in the Aegean the phosphates are entirely lacking and the nitrates less than 5 per cent of the quantity in the Atlantic. Presumably owing to the meagre precipitation of organic debris, the bottom fauna, evaluated by means of Petersen's bottom-sampler, was found to be exceptionally poor in the Gulf of Naples (0.5 gm per sq m), somewhat better in Algiers Bay (20 gm per sq m), and more like the conditions in

northern waters outside the Straits of Gibraltar (50 gm and more per sq m). Hard-bodied animals, Crustacea, corals and star-fishes, which have specialised in the utilisation of inorganic materials, are more or less strongly represented in the Mediterranean, but the soft-bodied animals, Mollusca, are deficient to a remarkable extent. This poverty of the waters and sea bottom of the Mediterranean gives an explanation of the dominant features of the piscine fauna, the scarcity of stationary species, the seasonal abundance of the migratory species, for example, of the herring and mackerel families, and the comparative absence of the gadoid and flatfish families, which form the chief marine food of northern peoples.

We obtain glimpses here and there also of other researches pursued by Prof Schmidt. For nearly twenty years now he has been carrying on an

intensive study of the races of fishes (eels, gadoids, *Zoarces*, etc.) and the causes of variation. In this pursuit, not content with the mere statement of variations in many thousands of specimens from many places, he has turned to direct experiment. The various theories connected with variation, heredity, natural selection, and the influence of environment have been tested by searching inquiry, and when the resources of the Carlsberg Laboratory proved insufficient for his purpose, he has made the waters round the Danish Islands, where the transitional conditions offer exceptional opportunities, his field of experimentation. These experiments, which fit in so well with his more general investigations, are approaching another milestone in their progress and seem destined to throw light not only on the causes and persistence of variations, but also on the origin of species. H M K

### Nikolaus August Otto, 1832-1891

AMONG the names of the hundreds of inventors through whose individual efforts the internal combustion engine has reached its present state of efficiency, that of Nikolaus August Otto will always be associated with the invention of the atmospheric gas engine and with the introduction of the four-stroke or Otto cycle for gas engines, which formed the subject of his German patent of Aug 4, 1877. Since then, the Otto cycle has been applied to internal combustion engines to an extent little dreamt of by the inventor, and it has proved of such fundamental importance that it may almost be compared with the invention of the separate condenser for the steam engine by Watt about a hundred years earlier. There are, it is true, many internal combustion engines running on the two-stroke cycle, but the vast majority of the millions of engines found in power-houses, factories, ships, motor cars, and aeroplanes to-day work on the four-stroke cycle.

Otto was born on June 14, 1832, at Holzhausen in Nassau, and died on Jan 26, 1891, at the age of fifty-eight years, at Cologne, where he is buried and where his centenary was commemorated on Tuesday last. The celebration was arranged by the Cologne section of the Verein Deutscher Ingenieure, and the address on the work of Otto, which was broadcast, was given by Dr A. Langen. To mark the occasion the Newcomen Society sent a chaplet with a suitable inscription, to be placed on Otto's tomb, in the Friedhof Melaten.

Otto's first occupation was that of a commercial traveller, and it was while engaged in business in Cologne that his attention was attracted to the gas engine. Considering it possible to make a gas engine capable of competing successfully with the steam engine, Otto began inventing, and through this was brought into contact with the engineer, Eugen Langen (1833-1895). On March 31, 1864, the two entered into partnership as N. A. Otto and Co., on April 21, 1866, they patented the vertical atmospheric gas engine with the free piston, and in the

following year exhibited one of their engines at the Paris Exhibition. The fuel consumption of this engine was far less than any of the French engines, and, thanks largely to their countryman, Prof Franz Reuleaux (1829-1905), one of the jurors of the Exhibition, the work of Otto and Langen was duly recognised.

This proved the turning point in the fortunes of the firm, for, encouraged by Reuleaux, the partners decided in 1869 to erect a factory at Deutz near Cologne, and in 1872 they formed the firm long since known as the Gasmotorenfabrik Deutz A.-G. At the same time, they secured the services of Gottlieb Daimler (1834-1900), the future inventor of the light spirit engine, and with him came Wilhelm Maybach (1846-1929), the future constructor of famous motor-car and aircraft engines. Otto now returned to his earlier experiments with engines working on the four-stroke cycle—a method of operation, it should be remembered, which was described in a pamphlet in 1862 by the Frenchman Alphonse Beau de Rochas. Success was achieved in 1876, the patent secured in 1877, and a four-stroke engine was exhibited at the Paris Exhibition of 1878. With this a new chapter in the history of gas engines began. Their manufacture was taken up by makers in various countries, notably in England by Messrs Crossley Brothers, and Otto gas engines soon became known all over the world.

Like many other persevering pioneers, no sooner had the Deutz firm achieved success than they found themselves drawn into litigation, and in the end the verdict was given against them and their patent declared void. But although it can be clearly shown that many of the ideas incorporated in the Otto engine had been previously thought of by earlier inventors, nothing can detract from the merits of Otto as the first to bring to fruition the valuable plan of operating gas engines on the four-stroke cycle. This alone will always secure for him a place among the greatest pioneers of the internal combustion engine. E C S

## Obituary

PROF MAX RUBNER

BY the death of Geheimer Obermedizinalrat Prof Max Rubner on April 27, the world has lost one of the most outstanding workers in the field of general nutrition. Rubner, born on June 2, 1854, belonged to the older school of workers who were interested in nutrition, for the most part, from its quantitative aspect, but although his greatest contributions to science were made in this field, even to the end he had also a lively interest in the qualitative side. A student in Munich, he became early in his career interested in the problems of metabolism and naturally gravitated to the laboratory of Carl Voit, becoming, after having spent a year in Ludwig's laboratory, one of his assistants and eventually Privatdozent (1883). In 1885 he was appointed to the newly founded chair of hygiene at Marburg as extraordinary professor, becoming *ordinarius* two years later. In 1891 he was called to Berlin to succeed R. Koch in the chair of hygiene there. This chair he retained until 1909, when he transferred to the chair of physiology in Berlin, vacant by Engelmann's death. This post he held until 1922, when he retired from active professorial work. He was Rector of the University of Berlin in 1910-11.

Rubner was undoubtedly one of the most energetic and stimulating workers in German biological science. In his early days with Voit he confined his attention to metabolic problems. It can be fairly stated that it was he who was mainly responsible for the application of the physical conceptions of Helmholtz and Mayer to biological material. Although he was not the inventor of the bomb calorimeter for the determination of the heats of combustion of foodstuffs, it was his research work in this field which established not only the crude but also the biological calorie values of protein, carbohydrate, and fat, which are accepted as international standards to-day.

Rubner's interest in the energetics of metabolism, begun in Munich, led at Marburg to extraordinarily fruitful research. It was during his Marburg period that he devised his ingenious animal calorimetric work, which enabled him to put forward his law of the specific dynamic action of foodstuffs and to give final and conclusive proof of his fundamental conceptions on the relation of the energy expenditure of an animal to its surface area. This period of his activity is reflected in his most original contribution, "Die Gesetze des Energieverbrauchs" (1902). This is undoubtedly a great but a very difficult book. It used to be said that there was only one man in Europe who could interpret it, and that was not Rubner himself but his friend and former Marburg colleague, Hans Meyer of Vienna. Rubner literally established the energetics of metabolism on a solid and lasting foundation.

Although his view of the work to be carried out by a professor of hygiene would seem at first sight to have been more of the nature of experimental physiology, Rubner did not neglect, particularly

after his translation to Berlin, the other aspects of his subject, as his many papers on public health subjects and finally his excellent textbook of hygiene (1907) attest. The range of his interests is simply astonishing, as is also the general high level of the material published.

Undoubtedly the subject nearest Rubner's heart was nutrition in the broadest sense of the term—nutrition as it concerned the people, its relation to growth, to general health. In addition to special sections on food in several large handbooks, he published several volumes of his own, for example, "Kraft und Stoff im Haushalt der Natur" (1909) and "Volksernährungsfragen" (1908), as well as numerous papers in the *Archiv für Physiologie* and other journals.

During the War years, Rubner played an active part in the working out of diets and the determination of the biological food value of various 'food substitutes'. Even after his retirement from his professorial chair, Rubner interested himself actively in the development of the Kaiser-Wilhelm Institut für Arbeitsphysiologie, Berlin (now in Dortmund). He was a member of many Government committees, and was for many years secretary of the Prussian Academy of Sciences, the *Sitzungsberichte* of which contain many of his interesting general papers.

E P C

MR R H ADIE

RICHARD HALIBURTON ADIE, of Trinity College, Cambridge, died on May 18, in his sixty-eighth year. To University, County, and Town he was for many years a familiar figure, and in their activities his work and personality were widely respected. It was the privilege of few to see so closely and for so long the development of agricultural education in Great Britain. In the first agricultural course held in Cambridge, commencing in 1891, Adie was a fellow-student of the late T. B. Wood and Cecil Warburton. His first appointment was as an extension lecturer in agriculture in Devon, which he relinquished to return to Cambridge. A small band, with vision and enthusiasm, had created the Cambridge and County Committee for Agricultural Education, and in 1895 he gave for them the first course of lectures in agricultural economics. Adie's initial studies had been principally in chemistry, and on returning to Cambridge he took charge of the chemical laboratory at St John's College. College teaching in chemistry continued until the outbreak of the War, and great numbers of men look back to the geniality and patience under which they began the study of chemistry in St John's.

The year 1899 saw the creation of a Department of Agriculture in the University. It was housed in two basement rooms of the University Chemical Laboratory, the head of which, the late G. D. Liveing, was its most valued friend. Resources were meagre, but the faithful service and remarkable versatility of the pioneer teachers laid foundations for the big developments which were to come.

Adie played an important part here as lecturer in agricultural engineering, surveying, and chemistry, and no less valuably in general development. Happily for the future of agriculture in Cambridge, his interest in civic matters grew rapidly at this time. By 1907 he was a member of the Cambridgeshire County Council, a body on which he served to the end of his life. He was also a member of the Cambridge Borough Council, becoming an alderman in 1914. In these early days, the financial support and the sympathy of the counties for agricultural education was of primary importance, and Adie's constantly growing influence in county administration enabled him to arouse among farmers and landowners a realisation of the part education could play in agricultural progress.

By 1914 the (then) Board of Agriculture scheme for advisory officers had been launched, and Adie became first secretary of the Provincial Council administering it. Throughout the War he was secretary of the Cambridgeshire Agricultural Committee. The School of Agriculture had to bear a full share of the sudden, heavy burden of reorganisation and pressure from students, brought by the cessation of war in 1918-19. It fell to Adie to lecture in engineering and surveying for both agriculture and forestry and in elementary chemistry and physics. In addition, he was secretary of the Special Board for Agriculture and Forestry, which, in its later form, the Faculty Board of Agriculture and Forestry, he served until his resignation in 1929. The lectures in agricultural engineering he continued to within a few weeks of his death.

Adie impressed his pupils by kindness, patience, and a *flair* for demonstration. His colleagues recognised in him a master of administrative procedure, a man of great stability, tenacity, and self-possession. To younger men, including those to whom by degrees he handed over his duties, he gave help, advice, and encouragement unsparingly.

#### DR H SEIDELIN

DR HARALD SEIDELIN, who died at Antwerp on April 29, was born at Aarhus (Denmark) in 1878, and studied medicine at the University of Copenhagen. In 1904 he went to Mexico, and became professor of pathology and bacteriology in the University of Yucatan, where his work was mainly concerned with investigations into the cause of yellow fever. He returned to Europe in 1910, and the following year joined the staff of the Liverpool School of Tropical Medicine as scientific secretary to the Yellow Fever Bureau. He took part in expeditions of the School to Yucatan and Jamaica to study yellow fever, vomiting sickness, and other obscure tropical diseases, and in 1912 he described certain minute bodies, found in the erythrocytes of yellow fever cases, which he believed to be the causative agent of yellow fever. He gave them the name, *Paraplasma flavigenum*, but his view of the parasitic origin of yellow fever was finally refuted in 1914 by Wenyon and Low. The last seventeen years of Dr Seidelin's life were devoted to the organisation and development of the medical service of the S A des Huileries du Congo Belge (Lever Brothers). Under his able and energetic leadership this service rose to a high state of efficiency, and he was honoured by the Belgian Government in 1929 with the decoration of Chevalier de l'Ordre Royal du Lion. Seidelin was a hard worker, a capable administrator, a careful investigator, and a brilliant linguist, speaking fluently half a dozen languages.

WE regret to announce the following deaths

Prof J W Gregory, F R S, emeritus professor of geology in the University of Glasgow, aged sixty-eight years

Prof A A von Jaczewski, director of the Phytopathological Institute in Leningrad, on Feb 12

### News and Views

#### New Associates of the Royal Astronomical Society

THE following have been elected associates of the Royal Astronomical Society. Prof Giorgio Abetti, director of the Royal Astrophysical Observatory at Arcetri, Florence, who is known for his observations on the chromosphere and on solar prominences, Prof R Emden, professor of physics, Technical High School, Munich, and author of "Gaskugeln" (1907), which consolidated and extended earlier work on the internal constitution of the stars, and has been the foundation of more recent work on this subject, M Ernest Esclagon, director of the observatories at Paris and Meudon, who in addition to astronomical work has carried out a gravity survey in south-western France, Prof H Ludendorff, director of the Potsdam Observatory, and in 1920-30 secretary of the Astronomische Gesellschaft, distinguished for his work on stellar spectroscopy, Prof P J van Rhijn, director of the Kapteyn Astronomical Laboratory, Groningen, Holland, author of numerous papers on the proper motions and distribution of the stars.

#### Franklin Institute Awards

THE following medals, among others awarded by the Franklin Institute, Philadelphia, were presented on May 18. Franklin Medals to Dr Ambrose Swasey, of Cleveland, Ohio, for his development of methods and his invention of appliances for making machines, tools, and instruments of the highest precision, of the design and construction of the mountings of many of the world's largest telescopes, and for his scientific vision in the establishment of the Engineering Foundation for the promotion of research and its application in the various fields of engineering, Dr P Lenard, of the University of Heidelberg, in recognition of a life's work devoted to fruitful research in physics, which has included the demonstration of cathode rays outside the generating tube and their effects, the discovery of the electronic nature of the emission from surfaces upon which ultra-violet light falls, as well as the basic laws of photoelectricity. Elliott Cresson Medals to Dr P W Bridgman, of the Jefferson Physical Laboratory of Harvard University, Cam-

bridge, Massachusetts, for his fundamental contributions to the technique of high pressure experimentation and to our knowledge of the properties of matter at high pressures, Mr C Le G Fortescue, of the Engineering Department of the Westinghouse Electric and Manufacturing Company of Pittsburgh, Pennsylvania, for the development of the method of symmetrical co-ordinates applied to the solution of poly-phase networks, Dr J B Whitehead, Dean of the Engineering School of Johns Hopkins University, Baltimore, Maryland, for his investigations of dielectric behaviour and allied subjects Howard N Potts Medal to Prof G P Thomson, of the Imperial College of Science, London, for his experimental demonstration of the wave properties of high speed electrons

#### Sir James Hall, Bt, 1761-1832

"AMONG Hutton's friends", wrote Sir Archibald Geikie in his work "The Founders of Geology", 'there was one in particular to whom a distinguished place in the list of the founders of geology must be assigned—Sir James Hall of Dunglass To this original investigator we owe the establishment of experimental research as a branch of geological investigation' The heir to a considerable estate at Dunglass, Haddingtonshire, Hall was born there on Jan 17, 1761, and died at Edinburgh on June 23, 1832—a century ago After three years travelling on the Continent, he married a daughter of the Earl of Selkirk and settled at Edinburgh, where he soon became familiar with the interesting group of men who made Edinburgh famous as a centre of scientific thought He was especially friendly with Playfair and Hutton, being greatly interested in the geological controversies of the time, and after opposing some of the views of Hutton, became one of his keenest supporters It was this that led him to make a long and laborious series of experiments on the fusion of various substances "These experiments", said Humboldt in *Cosmos*, "made more than half a century ago, together with the attentive study of the phenomena of granitic veins, have contributed in a very high degree to the recent progress of geological science" For many years Hall was a fellow of the Royal Society of Edinburgh, and at one time served as president. His bust was placed in the Royal School of Mines many years ago

#### Sir Prafulla Chandra Rây

WE have received from India some press accounts of the celebration organised by the Lahore branch of the Indian Chemical Society of the seventieth birthday of Sir P C Rây, who is well known as a chemist The great services rendered to India both in a scientific and national capacity by Sir P C. Rây were emphasised by the speakers His students have been active in furthering the cause of chemical science and education in India along the lines laid down by their teacher, and the foundation and growth of the Indian Chemical Society may be regarded as indications of the development of the methods which guided his activities in the promotion of chemical science in India. Sir P C Rây's experimental work is well known in Europe,

and his "History of Hindu Chemistry" is the only work of its kind in a European language The reports also lay stress on his excellent work in the relief of distress in India, and in encouraging and helping poor students in Bengal especially A portrait of Sir P C Rây was unveiled in the Library of the University Chemical Laboratory at Lahore, and a fund is to be started for the assistance of students In a communication from Calcutta, it is stated that a memorial volume of about 500 pages in English and native languages and dealing with several subjects is to be published

#### Calculating Machines and Scientific Investigation

A DISPLAY of calculating machines was arranged early this month by the Burroughs Adding Machine, Ltd, at 136 Regent Street, London, W 1 The machines shown were of many types, ranging from the simpler hand adding machines (which can also be used by the skilled operator for multiplication and division) to the complex electrically driven Calculating-Book-keeping Machine, which can be set up by adjusting a system of controls to carry out a variety of different automatic functions It is interesting to note that these machines, designed originally to deal with problems of costing and book-keeping, can be readily employed to simplify a great variety of computing problems. The mathematician, physicist, or statistician is often discouraged from attempting a problem involving the numerical solution of equations, the calculation of quadratures, or the forming of auxiliary tables, because of the apparently prohibitive amount of numerical computation involved It is possibly not generally realised, however, to what extent such work may be simplified and quickened up by the help of these modern aids to computing The machines are of course expensive, if needed only for occasional work, but the matter is really one for co-operation

WE are familiar with the importance of design in scientific experiment, design also is required in fitting a computing problem to a calculating machine, and the skilled designer in this field is already making a useful contribution to scientific investigation In the past a difficulty has been that the machine expert was unable to understand the problems of the mathematician, it is therefore interesting to learn that the Burroughs Company has realised the advantage of including trained mathematicians on its staff Another field for the adaptation of these machines is also in view There are signs both in Great Britain, in Germany, and in the United States of a growing interest in the development of scientific method in industry along the lines of statistical control of the quality of the manufactured product. Should the manufacturer begin to realise the function of statistical analysis in the problem of sampling and of testing and standardising material, he may require his calculating machine to provide him with standard deviations and coefficients of correlation If so, the machine makers should be ready to give advice on how best to proceed in this field, as well as in the problems of accountancy and costing

### The Joicey Collection of Lepidoptera

RECENT remarks by a learned and very senior judge in the Chancery Division, who was engaged in the hearing of a summons concerning the disposal of the very valuable collection of Lepidoptera formed by the late Mr J J Joicey, serve to direct attention to the extraordinary lack of knowledge of natural history matters prevalent even amongst those whom one is accustomed to regard as amongst the best informed. The judge in this case is reported to have said that "He had never been to the Museum since he was taken there as a boy, much to his discomfort, and he always thought there was too much to see. If the collection went elsewhere it might be seen to better advantage." The museum concerned in the case was the Natural History Museum. Should the judge even now, however, care to make amends, it is safe to say that he will be spared the horror of having to 'see' the Joicey collection should it eventually, as is hoped, find its way to South Kensington, for, as is common knowledge amongst naturalists, it is not the policy of the British Museum (Natural History) to display to the public collections of such great scientific value as this. Indeed, it would be impossible to do so in this case, for the 250,000 specimens involved would need a whole gallery (which is not available) for their accommodation. Surely it is time judges and others in high position ceased to express gratuitous opinions of the kind mentioned, which, in the long run, may do incalculable harm to the parties involved and, not least, to the respect in which the administrators of the law are normally held. Fortunately, in the case of Mr Joicey, the decision of the court, although it was not what it was hoped it would be, may still not prejudice the ultimate gift of his collection to the nation by the trustees of the estate of which it at present forms part.

### Waste in Education and Chemistry

PROF HENRY E ARMSTRONG is a provocative speaker whose observations in public are generally as pungent as they are pertinent, as a writer he excels in the art of garnishing a deal of common sense with a deal more of trenchant criticism. As a chemical criminologist Prof Armstrong has no equal, for many decades he seems to have watched his fellow chemists and educationists stray from the obvious path of rectitude and fall one by one into every kind of intellectual disgrace. Such unrivalled experience, together with the habit of fearless insistence on the importance of the most important things, serves to equip him admirably to play the double part of detective inspector and prison chaplain. On two occasions recently Prof Armstrong has said much that was well worth saying, and has added a good deal that, in our opinion, is more likely to diminish than to enhance the brilliance of his analysis. The first address, delivered before the Imperial College Chemical Society in January last, was entitled "Waste Chemistry", and the second, delivered before the London and South-Eastern Counties Section of the Institute of Chemistry in February, was entitled "Shifting Sands". Prof Armstrong detests waste—including most of the chemistry that is taught in schools and colleges. He

deplores waste of effort in the perpetual killing of the slain under the disguise of new jargons. There is considerable point in his stricture (provided it be remembered that it is one thing to kill a dragon but quite another to keep it dead), whether or not this waste of opportunity is "owing to a cultivated and obtuse narrowness of vision"—and he can have full marks for the debating point. But this is not all, in addition to being wasters, we have no sense of proportion and no ability to work problems out to a logical end. Again, all this is probably true in some degree of most of us and in greater degree of some of us.

STILL, the crimes alleged against the prisoner have not all been stated, according to Prof. Armstrong, our educational system is simply dishonest, being calculated to promote selfishness and to give employment to a maximum number of people, all bent, through their inability to think, on using their ignorance in misleading learners. A statement of this kind is purely provocative, and ought not to be made by Prof Armstrong or anyone else. It ignores a vast amount of unselfish and earnest educational service, and despises the efforts of thousands of men and women of at least average ability and usually possessing some sense of public duty and private responsibility. The educational army, nevertheless, will continue its march, whether or not Prof Armstrong is the only one in step. To return to the addresses, and to discover in them things worth recording. Prof Armstrong is undoubtedly right when he warns us that the nations cannot much longer allow the uncontrolled waste of natural resources to continue. Industry of every kind, he rightly says, must be controlled and organised with due reference to both raw materials and requirements, instead of being allowed to proceed, without thought of policy, merely as speculative, individual adventure. Emphasis is laid, too, on the relation of scientific discovery to the use of labour, and the attention of scientific people and employers of scientific people is directed to the need for discovering and directing labour-using rather than labour-saving occupations.

### Social Selection of Human Fertility

THE Herbert Spencer Lecture was delivered at Oxford by Dr R A Fisher on June 8 on "The Social Selection of Human Fertility". After recalling the consistent efforts of Spencer towards the unification of the natural and social sciences, Dr Fisher spoke of the hypothesis of complete determinism that has been held, as by Laplace, in the sphere of probability. From the course of physical investigation it might be plausibly conjectured that the mathematical formulæ, being often more accurate than the observational results, must more nearly represent reality, and hence that any fortuitous element can be excluded from physical phenomena. Researches, however, into the nature of the ultimate particles of gases do nothing to strengthen the deterministic position. The only principle on which the behaviour of a system can be predicted is that its properties are the average of a large number of independent items of behaviour. Human societies may be large enough

to show natural causation, where their constituents may be regarded as independently active. Limitations are imposed by organisation and by public opinion, but there are features of society which appear to be exempt from such limitations. These are (1) the hereditary endowment received by each generation, and (2) the individual reactions, though not the conditions, of what may be called the process of social promotion.

THERE is a presumption, Dr Fisher said, that at the present day social promotion depends more on intellectual superiority and less on business aptitude than it did, say, a hundred years ago. Though no occupational class is strictly endogamous, the differences produced by selection for occupational status tend to be perpetuated. An unintentional feature that has arisen in our economic system is that the highest forms of ability are united with relative sterility, and vice versa. Whether a similar process was present in past civilisations it is for historians and archaeologists to decide, but in regard to Great Britain "it is difficult to avoid the conclusion that a full half of whatever eugenic value this [fairly well-to-do] class contains may be counted as already lost." There is, Dr Fisher concludes, no ground for fatalism, but in considering the causes of an impending evil, we should as scientific workers distinguish between the inevitable and the avoidable, and as citizens we should in the latter case see to the application of the requisite control.

### Science and Philosophy

IN his recent presidential address to the British Institute of Philosophy, under the title "Philosophy and the Ordinary Man", Sir Herbert Samuel pointed out that although all action and thought is the conscious or unconscious product of a philosophical attitude, the ordinary man takes little interest in philosophy, with which he thinks he has no concern. In this respect philosophy contrasts strikingly with science, which arouses widespread interest. The reason is partly that expositors of science do not disdain to write in the vernacular, whereas many philosophers find it necessary to use a special terminology. It is chiefly, however, that science consists predominantly of a body of knowledge which commands common assent, whereas philosophy is largely an aggregate of individual systems of thought. Nevertheless, it has an important function to perform in constructing an authoritative code of morals for the guidance of those bewildered by the progress of science. It could best do this, said Sir Herbert, and at the same time command greater public interest, if it could be induced "to turn aside from *a priori* methods, to put no great faith in Logic as a guide, and to press forward into the realms of metaphysics and ethics along the roads opened up by mathematics, physics, biology in general and psychology in particular, and by the social sciences."

### The Principle of Causality

THE first principle which philosophy might receive, as established by science, is the principle of causality, which, in spite of recent attacks by some physicists,

still reigns supreme. In support of this contention, Sir Herbert Samuel quoted a letter from Einstein and the published opinions of Planck. The principle of causality leads in philosophy straight to a theistic position, for since the universe is not self-explanatory, there must be "something else." We cannot, however, at present fathom the nature of the Divine Mind. The principle of causality appears to deny human free-will, but although from a universal point of view this is so, events in the limited sphere of human action proceed as though our wills were free, and practical life must be conducted on that footing. A further application of the principle of causality in philosophy leads to a definition of the 'Good' as that which experience shows to promote well-being, rather than as an ideal standard of values. In the general adoption of the scientific method, philosophy will find its chief opportunity and its main strength.

### Harrison's Third Marine Timekeeper

OF special interest among recent additions to the Science Museum collections is the third of the series of four chronometers designed and constructed by John Harrison between the years 1728 and 1759, this instrument has been lent by the Lords Commissioners of the Admiralty. The British Government had in 1714 offered an award of £20,000 for an accurate method of determining longitude at sea. It was realised that the problem could be solved by carrying on board ship a trustworthy timekeeper, and Harrison set himself the task of constructing such an instrument, after devoting practically his whole life to the work, he succeeded in winning the award with his fourth timekeeper. Harrison's No 3 timekeeper is designed so as to be unaffected by the motion of a ship, while on account of the extensive use of friction wheels it requires no oiling, it also embodies original and ingenious methods of compensation for variations of temperature and of arc. The chronometers Nos 2 and 3 are now shown in motion side by side in the Science Museum, No 4 is at the Royal Observatory, Greenwich.

### Zoological Collections of de Sélys

MANY specialists on the systematics of the Vertebrata are under the mistaken impression that the famous collection made in the course of the nineteenth century by Michel Edmond de Sélys-Longchamps is either destroyed or lost. Happily this is not so. The collection was preserved in the Chateau de Longchamps près Waremmes, Belgium, where it occupied the little museum which de Sélys built, but it was not readily accessible to specialists and was in the care of an old servitor. The fate of this collection, which is a veritable treasure-house for mammologists and ornithologists, has just been settled in a way which will give widespread pleasure. Barons Maurice, Raymond, and Edmond de Sélys-Longchamps, grandsons of the great zoologist, have given the whole collection to the nation, and it is being placed in the Royal Museum of Natural History at Brussels. Thus all de Sélys' zoological collections are brought together again, for in 1900 de Sélys bequeathed his important entomological collection to the Museum.

### American Expedition to Northern India

SINCE the beginning of March an American scientific expedition sent out by Yale University has, under the leadership of Dr Hellmut de Terra, been doing geological and biological research in Northern India. Having visited the Salt Range, Dr de Terra and Prof G E Hutchinson, a biologist at Yale University, have proceeded to Kashmir, where they are making a geological and biological survey of the Kashmir valley. Ultimately they hope that this survey will make possible a clear understanding of the natural history of this southern Himalayan sector, from the pleistocene period to the present day. Another member of the party, Mr G E Lewis, fellow in palaeontology at Yale, has been collecting tertiary vertebrate fossils in the Siwalik formations of the Northern Punjab. On May 15 the expedition, accompanied by the surveying officer Khan Sahib Afraz Gul Khan, left Srinagar and started for the Eastern Karakorum, a field in which Dr de Terra has already done geological work while accompanying Dr Trinkler's Central Asia Expedition. Five months will be devoted to work in this region, which includes the still little known tract of land lying along the north-west Tibetan plateau. While the rest of the party will be busy with geographical and geological problems, Prof Hutchinson plans to carry out limnological studies on the great Pangong and adjacent lakes which are among the highest lakes in the world.

IN reference to the work of this expedition in the Salt Range, Dr L L Fermor, officiating director of the Geological Survey of India, writes from Calcutta to point out that a note in these columns (*NATURE*, Feb 20, p 275) on the plans of the expedition—which was based on an announcement issued by Science Service of Washington—"seems unjust to the Geological Survey", in suggesting that the Salt Range had not been examined systematically for palaeontological evidence. Dr Fermor directs attention to a number of contributions to the *Memoirs of the Geological Survey* and *Palaeontologica Indica*—on the geology by A B Wynne and Sir Edward Pascoe, and on the palaeontology by R Lyddeker, G E Pilgrim, W. Waagen, and others. In addition, Dr Fermor states that the Range itself is now being surveyed in great detail by E R Gee.

### Early Man in Palestine

FURTHER information relating to the human skeletal remains found in the Mousterian strata of the Palestinian cave, Mughareet es-Sukhul (see *NATURE*, May 14, p 712), as given by Miss D A E Garrod in a communication to the *Times* of June 11, indicates that the discovery is of even greater significance than at first appeared. Now that Mr MacCown and his assistants have been able in part to remove the breccia in which two of the skeletons were embedded, it is becoming possible to appreciate the bearing of certain incompatibilities with the Neanderthal type, which Sir Arthur Keith had noted in the Gahlee skull and other remains found in the Palestine caves in association with a Mousterian culture. These two

skeletons are practically complete and lie as they were buried, one on its back, the other on its left side with legs flexed and heels drawn up towards the sacrum. Although the skull has the characteristic powerfully developed supraorbital ridges, the cranial vault is higher and the head somewhat rounder than in Neanderthal man, while viewed from behind, the greater breadth appears nearer the base and the sides are comparatively straighter, converging slightly towards the top of the head. Even more remarkable is the facial skeleton, which appears to exceed in prognathism the most prognathous of Neanderthal skulls, giving it an ape-like appearance. The lower jaw is as heavy and as squarely built as in Neanderthal man, yet it has a decided chin. The limb bones are massive but longer than those of Neanderthal man, but it is evident that Palestine man walked with the Neanderthal slouch. In view of these facts, Sir Arthur Keith confirms the conclusion of the excavator that here we have a new race, or even a new species, of fossil man, for which Sir Arthur proposes the name *Palaeanthropus Palestinus*.

### Tornadoes in the United States

IN the *Monthly Weather Review* for last December there is a preliminary report on the frequency of tornadoes in the United States during 1931, on the number of deaths caused by them, and on the material damage. This report shows that in the past year tornadoes were notably scarce compared with other recent years, and did less damage than usual, also that, what is even more satisfactory, they caused less than half the number of deaths recorded in any of the previous fifteen years. Even so, the death roll, resulting from about ninety of these visitations, reached 34, of which no fewer than 14 occurred last December. The unit in which material damage is expressed is the sum of a thousand dollars, and in five months the total damage thus expressed ran into three figures, September was outstanding with 828,000 dollars' worth of damage caused by twelve or thirteen tornadoes. The figures for monthly frequency of occurrence of the storms show a characteristic early summer maximum, with a total of 32 storms in May and June, that is, of more than a third of the year's total. It may be noted that although the tornado and the commonest type of summer thunderstorm are probably both caused by local instability due to the juxtaposition of air masses of different temperature, of which the warmer generally carries a great quantity of water vapour, they must be regarded as in some way essentially different in their modes of origin.

### The Five-Year Plan in Russia

A SERIES of economic studies of Russian production under the Five-Year Plan is being published by the Bureau of Research of the Russian Department of the University of Birmingham, under the editorship of Prof S Kononov. No 5 deals with the economic results for 1931, agricultural collectivisation, and oil production and export. The statistical presentment of the plan is of much interest. As regards agriculture, it is shown that while the 1913 output of

cereals was 81.6 million tons, the average output in 1927, 1928, and 1929 fell to 72.9 million tons, or a decrease of 10.7 per cent. This, however, was increased in 1930, under collective farming, to 87.4 million tons, but the hopes for 1931 of 97.9 million tons fell short by as much as 21.5 million, which, with an annual growth of population of 2.36 per cent, has meant a cessation of export. The shortage would appear to have been largely due to vain attempts to increase too rapidly the area under cereals, which led to badly prepared soil, thin sowing, and delayed harvests. Less favourable weather was another cause. Nevertheless, the sown area of cereal and other crops has been increased during the last year by more than seven per cent. An analysis of the output of large scale industry shows an increase in the last year of 21.7 per cent, against the anticipated 44.3 per cent. At the same time, there are other negative results which are fully analysed in this report, such as the decrease in the productivity of labour, and the increase in cost of production and in prices.

#### Antirabic Treatment in India

THAT dread disease hydrophobia, caused by the bite of rabid animals, is of considerable importance in India, and 456 deaths were attributed to it in 1930 in the Madras Presidency. The report for 1930 of the Director, Major Iyengar, of the Pasteur Institute of Southern India, Coonoor, records that 541 patients were treated at the Institute, with 5 deaths, a mortality rate of 0.92 per cent. In addition, 4747 cases were treated at other centres in the Madras Presidency, with 5 deaths. Semple's carbolic sheep vaccine was used throughout, the virus being in its 1154th passage at the end of the year. Animals to the number of 229, including one elephant, were also treated, with no death. Bites treated were inflicted by eleven species of animals, including man, panther, leopard, jackal, and fox.

#### Investigation of the Atmosphere in the U.S.S.R.

A SCIENTIFIC institute has recently been established in Moscow to carry on research on the circumstances of formation of cloud, fog and rainfall. The institute has branches in Leningrad, Odessa, Saratov, Tashkent, and Ashkhabad. The Leningrad branch of the institute is installing apparatus for investigating the effect on the atmosphere of high-tension currents, X-ray, ultra-violet rays and radioactive radiations. It is hoped to test the apparatus next summer in experiments to be carried out in the drought regions of the U.S.S.R.

#### Announcements

At a congregation held at Cambridge on June 11, the honorary degree of Sc.D. was conferred on Sir William Bragg, director of the Royal Institution.

DR HENRY S. WASHINGTON, the distinguished petrologist of the Geophysical Laboratory of the Carnegie Institution of Washington, has been elected an honorary member of the Mineralogical Society.

PROF. H. E. ARMSTRONG will deliver the next Huxley Memorial Lecture at the Imperial College of

Science and Technology on May 4, 1933. Prof. Armstrong will speak on Huxley's educational creed and its outcome.

THE following committee has been appointed to inquire into the sterilisation of mental defectives: Mr L. G. Brock (chairman), Dr Wilfred Trotter, Dr R. A. Fisher, Dr A. F. Tredgold, Miss Ruth Darwin, Dr E. W. Adams, Dr R. H. Crowley, Dr E. O. Lewis, with Mr F. Chanter, of the Board of Control, as secretary. The terms of reference are: "To examine and report on the information already available regarding the hereditary transmission and other causes of mental disorder and deficiency, to consider the value of sterilisation as a preventive measure, having regard to its physical, psychological, and social effects, and to the experience of legislation in other countries permitting it, and to suggest what further inquiries might usefully be undertaken in this connexion."

THE reports of the destruction of a gaol at Mymensingh, in Bengal, on May 9 last, by a tornado, were probably incorrect in attributing the damage to a tornado, for the 'nor'westers' are quite capable of doing all the damage described on this occasion and are particularly frequent in May. These squalls, associated with early summer thunderstorms in Northern India, can be very violent.

A NEW catalogue (No. 549) of second-hand books and journals has just reached us from Francis Edwards, Ltd., 83 High Street, Marylebone, W.1. It comprises nearly 1700 works—many rare—dealing with folklore and anthropology.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A lecturer in the Chemistry Department of the Heriot-Watt College, Edinburgh—The Principal, Heriot-Watt College, Edinburgh (June 20). A principal of the Walsall Technical College—The Director of Education, Education Offices, Council House, Walsall (June 25). A principal of the Chelmsford School of Art and Technology—The Director of Education, County Offices, Chelmsford (June 25). A lecturer in zoology (botany subsidiary) at the Chelsea Polytechnic—The Principal, Chelsea Polytechnic, Manresa Road, S.W.3 (June 30). A lecturer in the department of botany in the University of Durham (Durham Division)—The Head of the Department of Science, University of Durham, South Road, Durham (July 1). An F. W. Bennett lecturer in physics at University College, Leicester—The Registrar, University College, Leicester (July 5). A graduate assistant master to teach mathematics, with elementary science as subsidiary subject, in the Halifax Junior Technical School—The Principal, Municipal Technical College, Halifax. An assistant master for the teaching of painter's and decorator's work at the Huddersfield Technical College—The Director of Education, Education Offices, Peel Street, Huddersfield. A chief instructor in agricultural subjects at the Army Vocational Training Centre, Chisledon, Wiltshire—The Commandant, Army Vocational Training Centre, Chisledon, Wiltshire.

## Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

### The Inheritance of Acquired Characters

MR HALDANE professor of physiology in the Royal Institution, has adopted the unusual course of delivering an address in which he directly attacks a discourse which, at the request of the managers of the Royal Institution, I delivered a year ago, and an answer from me seems to be called for. Within the limits of a letter I cannot deal with what are in my opinion the fallacies in Prof Haldane's address, as to do so would involve writing another discourse. I shall have to confine myself to the cardinal points at issue, the more so as no one would have guessed from Prof Haldane's words either (1) what Lamarck really said or (2) what the argument in my discourse had been.

Briefly, then, my argument was this. Whenever we have evidence which enables us to determine with a probability amounting to practical certainty what the actual course of evolution has been we find that it presents the same features, namely, an extremely slow and continuous change of structure correlated with a corresponding slow modification of habit. Since changed habits, by exercising different parts of the body, do modify structure and since we know that animals can and do change their habits in response to the demands of a changed environment, it is a natural inference that the changed habits are the cause of the changed structure, and that the structural response of the individual has finally become engrained in the heredity of the race. So strong is the evidence for this inference, that some of my friends amongst the leading systematists of the British Museum deny altogether the necessity for direct experimental confirmation of it, arguing with probable justice that so many generations would be needed to make the change manifest that the time required would far exceed the span of an experimenter's life.

Lamarck did not, however, as Prof Haldane mistakenly suggests, suppose that external circumstances (that is, environment) produce a change which is afterwards produced by internal causes (that is, inherited). On the contrary, he stated explicitly that the environment produces *no direct modification of the animal whatever*. (Here he goes too far, there is little doubt that 'mutations' are produced by the direct action of the environment.) What modifies an animal, according to Lamarck, *is its own activity*. This activity, called forth by its needs in a new environment, *if it lasts for a long time*, eventually causes the formation of new habits, these in the long run lead to new structures and are reproduced in the young.

Now, the time at the disposal of an experimenter is only about five years, in very rare cases ten years, and it is too much to hope that in this brief time noticeable modifications of structure will be produced, but there is room for hope that new habits may be formed, and that these new habits may prove to have an influence on posterity. I pointed out that it would be entirely contrary to expectation to find that the new habit persisted when the offspring were replaced in the typical environment, at most we might expect an *intensification* of the habit when the

offspring were reared in the new environment, and a *lag* in the reversion to the parental habits when they were replaced in the typical environment.

These expectations, happily, have been fulfilled and I mentioned a number of experiments, three of which, I hold, afford conclusive proof of the influence of habit on posterity. These are (1) Durkhen's experiments in exposing the caterpillars of the white butterfly to orange light which suppressed the white colour of the pupal case and made the pupæ look green. When a second generation produced from these pupæ were reared in ordinary daylight, from 35 to 50 per cent were green. (2) Metalnikoff's experiments on the caterpillars of the beeswax moth, in which he inoculated some with a bacillus which proved uniformly fatal, whilst a control were inoculated with a vaccine which protected against the effects of the bacillus. Breeding from these immunised moths for several generations and inoculating each generation with the vaccine, he obtained a strain which were almost immune to the bacillus. (3) Heslop Harrison's experiments on the saw-fly, when he forced a saw-fly to lay its eggs on a plant to which it was not accustomed, and showed that in five years it had learned to prefer its new host plant to the old one.

If, as I think, every fair-minded person must admit on examining the evidence that these experiments are convincing, then the cardinal postulate of the Lamarckian theory is proved and we are free to apply it to explain the progress of evolution, and as a student of evolution all my life I can testify that the light which it throws on the process is amazing.

It is not surprising, therefore, that Prof Haldane attempts to explain away the results of these experiments, and he does this mainly by attributing them to selection. Now, though he claims to represent a new and insurgent group of younger biologists, his references to selection are evidences of an archaic type of thought. Selection as an effective cause of anything is a superstition which dies hard. That some animals live and some die is known to everyone, but unless the some that die differ from those that live, no change is produced. What a belief in selection really implies is that small inheritable variations in all directions are continually turning up *by chance*. The pure line experiments which Prof Haldane quotes were placed by me in the forefront of my arguments for Lamarckism, for they prove conclusively that such fluctuating deviations are not inherited, and hence they sweep away the main argument for Darwinism in its classical form. I am not alone in this opinion. In Germany these experiments have led to what is called "Der Krisis im Darwinismus".

Coming, however, to details. It provokes a smile to find Prof Haldane instructing Durkhen, who devoted five years to his experiments, what he must do in order to convince him, and asserting that there is not a shadow of evidence for anything more than selection. Durkhen carefully considered this point, and in later experiments put it to the test. He carefully selected the *darkest* of his pupæ (that is, the not-green), reared a second generation from them, which he exposed to orange light, and he obtained 96 per cent of green pupæ. There is no possibility, he says, of separating a green and a not-green race by selection.

The case for Metalnikoff is even stronger. Here according to Prof Haldane rigorous selection was used. This is an entire mistake, but I must admit that I did not in my discourse give a sufficiently clear account of these experiments.

Metalnikoff did not breed from the caterpillars which he had immunised and then inoculated with the bacillus. By preliminary experiments (which we

have repeated in my laboratory) he determined that the bacillus was uniformly lethal and that the vaccine afforded a constant immunity against it, then in each generation he immunised half the caterpillars and exposed half to the bacillus—but he always bred from the immunised half, and thus proved the cumulative action of the vaccine. Metalnikoff himself has no doubt as to the bearing of his experiments on Lamarckism, for in France, where he worked, the logical French mind has always clung to Lamarckism and has refused to be obsessed with the value of chance variations. Lastly, with reference to Heslop Harrison's experiments. Here again the argument for selection fails utterly, for the willow plant on which the saw-flies were forced to lay their eggs was a rare hybrid, and the supposition that Harrison was selecting an inborn 'gene' which conferred on the saw-fly larvæ the capacity to live on this plant is an hypothesis too fantastic for anyone except Prof. Haldane. As to the hypothesis of 'larval memory', which is at first sight a plausible one, it is untenable, because it assumes that the instinct of the mother to seek a certain plant and the capacity of the larva to live on this plant are inseparable. But Harrison by crossing two moths whose larvæ fed on different food plants obtained hybrids in which the mother sought the food plant of the paternal race but the unfortunate larvæ could only live on the food plant of the maternal race, and hence perished miserably.

Prof. Haldane makes a reference to my dead friend Kammerer. Let me then put on record that I believe that in time Kammerer will be completely vindicated, and this is the belief also of his teacher, Prof. Przibram. Kammerer was driven to suicide by the discovery that his type-specimens, the fruit of his life's work, had been tampered with and rendered useless. Whatever may happen in the future, one piece of Kammerer's work will endure, he succeeded in disproving for all time the hypothesis, endorsed by Prof. Haldane, that the blindness of cave-animals was due to their having by chance inherited eye defects—for in 1923 he produced in my laboratory large specimens of the blind cave-newt *Proteus anguinus* with fully developed eyes, evolved by exposing the animals at the proper stage of growth to the action of red light. This is the strongest indirect evidence yet adduced for the inheritability of the effects of disuse.

Finally, Prof. Haldane asks, "If we reject Lamarckism, what remains?" He answers, "Neodarwinism." The meaning of this term is doubtful. Certainly it signifies something which would not have been accepted by Darwin, for he remained half a Lamarckian all his life. I shall venture to define it as the theory of 'Chaos and Chance'. Certainly to anyone who accepts chance as an explanation, it is omnipotent and can be used to bridge any gap in the evidence. It is impossible to prove that a thing did not happen by chance, and the attitude which those of us who believe in regularity and law in this as in other departments of Nature must adopt towards the supporters of chance, is that recommended by Virgil to Dante concerning certain nondescript sinners whom they met at the entrance to hell, "*Non ragioniam di loro ma guarda e passa*."

The controversy between supporters of chance and habit as the cause of variation must ultimately be decided by the suffrages of biologists. I must say that I have been greatly cheered by the support which has reached me from all parts of the world, but I cherish particularly the memory of one incident. It is just fifteen years since I delivered my first lecture on this subject to a scientific society. I had the honour of having amongst my audience several distinguished scientific men, of whom one was the eminent physiologist, Prof. J. S. Haldane. After the lecture, I was

complaining to him of the prejudice which had to be conquered in order to persuade people of the inheritability of habit. "Well," he said, "one thing is certain unless it is true, there has been no evolution." With this opinion I cordially agree.

### Origin of the Coronal Lines

In two recent communications<sup>1</sup> de Bruin has given a group of numerical relations, which relate the strongest visible lines of the corona, 5302.78, 6374.28, 6704, and 6775.90, with certain lines of the O I spectrum. According to de Bruin, there exist in addition to the following well-known deep-lying O I terms  $^3P_{1,2,3} = 109,831, 109,672, 109,605$ ,  $^1D_2 = 93,962$ ,  $^1S_0 = 76,037$ , another group of deep-lying terms  $P, Q, R, X, Y, Z$ , 94,925.1, 94,905.3, 94,898.7, 79,221.7, 78,946.2,

FIG. 1.—Spectra of argon and oxygen. Argon lines marked above, oxygen lines below the spectra.

78,932.3. The intercombinations of these new terms one with another and with the already known existing deep terms,  $^3P, ^1D_2$ , and  $^1S_0$ , are supposed to give the hitherto unclassified corona lines 6775.90  $2p\ ^3P_1 - P$ , 6704  $2p\ ^3P_2 - P$ , 6374.28  $Q - X$ , 5302.78  $R - 2p\ ^1S_0$ , as well as some unclassified lines of the O I spectrum 6654.12  $Y - ^1D_2$ , 6366.28  $P - X$ , 6374.29  $Q - X$  (it has been suggested by Hopfield<sup>2</sup> that the last mentioned line is identical with the coronal line 6374.28), and 6266.69  $-(P, Q, R) - (Y, Z)$ .

The theoretically expected scheme for the deeper terms of O I has been completely observed and verified previously<sup>3</sup>, unknown higher terms of the configurations  $s^2p^3$  and  $sp^4$  are only to be expected with

negative term values. The question therefore arises as to whether the admittedly exact numerical relationships given by de Bruin have a true physical meaning or whether they are purely accidental, as in previous unsuccessful attempts correlating coronal lines with other spectra. Since, according to de Bruin, these suggested new terms lie very deep, it should be possible to prove their existence by determining experimentally whether they do all actually lie deep. The photographs (Fig. 1) show the part of the O I spectrum under discussion with different degrees of excitation. *A*, *B*, and *C* were taken with a wide discharge tube (3 cm bore, 60 cm long, 0.8-1.2 amp d.c.). *A* shows the spectrum given by argon which contains very small traces of oxygen. In this photograph appear the strongest lines of the quintet and triplet systems and also the green auroral line 5577  $^1S_0 - ^1D_2$  and also perhaps (between the argon lines 6296.8 and 6307.7) the line 6300.03 (according to Paschen,<sup>4</sup>  $2p\ ^3P_2 - 2p\ ^1D_2$ ). *B* is given by a mixture of a few millimetres of argon and a little more oxygen than previously. The auroral line appears now with great intensity, and in addition the lines 6300 and 6364 (according to Paschen,  $1c$ ,  $2p\ ^3P_1 - 2p\ ^1D_2$ ) are also fairly strong. Further, this photograph and all the others show the strongest lines of the triplet and quintet systems, which can be explained by cumulative processes of excitation. The weak line 6391.0 ( $2p\ ^3P_0 - 2p\ ^1D_2$ ), the third classified by Paschen, is not observable.

It is a remarkable fact that not one of the supposedly classified lines of de Bruin appears with this excitation, although the strong intensity of the auroral line shows that any deep terms greater than 76,037 must also be excited in this discharge. Photograph *C* is taken with pure oxygen of a few millimetres pressure. The energy of excitation is displaced to higher values, the lines 5577, 6300, and 6364 become weaker relative to the other series lines, but the group 6266-56 just begins to be visible on the original plate. The last photograph, *D*, was taken with 0.8 amp d.c. in a narrow quartz capillary tube of 2 mm bore.

According to my earlier observations,<sup>5</sup> this mode of excitation is peculiarly suited for the production of highly excited terms. In this case the maximum of excitation is now displaced to larger values, thus 5577 is very weak, and 6300 has disappeared.

In contradistinction, all the following lines of de Bruin, 6654, 6374, 6366, 6266-56, as well as the other highly excited lines (5995-5991, upper term = -20,135.2 to -20,142.8 according to de Bruin, 5750-5720, upper term -13,458 to -13,548 according to Frerichs), show considerable intensity. The fact that de Bruin's supposed combinations between deep terms give lines which only appear when the energy is sufficient to excite high-lying terms (negative) proves unambiguously that these lines must involve high-lying terms and not deep ones. It is of interest to note that Paschen and Hopfield,  $1c$ , who used a discharge tube with dimensions between those giving spectra *C* and *D*, actually obtained a spectrum intermediate between that of *C* and *D*.

The present experiments prove definitely that amongst the lines considered only 5577, 6300, and 6364 are lines of deep excitation. Hence the degree of accuracy of wave-length agreement between coronal and oxygen lines does not then come into the question. It therefore appears that the numerical

relations of de Bruin are merely accidental, so that the great mystery of the coronal lines remains unresolved.

R FRERICHS

Physikalisches-Technische Reichsanstalt,  
Charlottenburg, May 15

<sup>1</sup> NATURE, 129, 468, March 26, 1932, *Naturwissenschaften*, 20, 268 1932

<sup>2</sup> Phys. Rev., 37, 160, 1931

<sup>3</sup> R. Frerichs, *Phys. Rev.*, 36, 398, 1930

<sup>4</sup> Z. Phys., 65, 1, 1930

<sup>5</sup> Phys. Rev., 34, 1239, 1930

THE interesting letter of Dr. T. L. de Bruin on this subject<sup>1</sup> throws additional light on the spectrum of neutral oxygen, and is very suggestive in relation to the hitherto unexplained spectrum of the solar corona. It appears, however, to be premature to conclude that the coronal lines—in particular the green line at 5303—have now been identified. An analysis of the evidence submitted by Dr. de Bruin shows that the suggested interpretation of the green line rests on the existence of the term *R*, the reality of which can be established only by assuming a classification of his groups I and II of oxygen lines, which is not the most satisfactory that could be made. The oxygen lines in question are the following:

| Group I              |          | Group II             |          |
|----------------------|----------|----------------------|----------|
| $\lambda$ (m $\mu$ ) | $\nu$    | $\lambda$ (m $\mu$ ) | $\nu$    |
| 6654.121 (4)         | 15024.14 | 6266.692 (1)         | 15952.97 |
| 6374.292 (5)         | 15683.68 | 6264.346 (2)         | 15958.95 |
| 6366.282 (4)         | 15703.42 | 6261.314 (5)         | 15966.68 |
|                      |          | 6258.965 (1)         | 15972.67 |
|                      |          | 6256.616 (3)         | 15978.67 |

de Bruin's classification is as follows, the numbers in brackets indicating the differences between the observed values of wave-number and those calculated from his terms:

|                    | <i>P</i>       | <i>Q</i>       | <i>R</i>       | $2p\ ^1D_2$   |
|--------------------|----------------|----------------|----------------|---------------|
|                    | 94925.1        | 94905.3        | 94898.7        | 93970.3       |
| <i>X</i> = 79221.7 | 15703.4 (0.0)  | 15683.6 (+0.1) |                |               |
| <i>Y</i> = 78946.2 | 15978.9 (-0.2) | 15959.1 (-0.1) | 15952.5 (+0.5) | 15024.1 (0.0) |
| <i>Z</i> = 78932.3 |                | 15973.0 (-0.3) | 15966.4 (+0.3) |               |

It is possible, however, to arrange the lines thus:

|                     | <i>P</i>         | <i>Q</i>         | $2p\ ^1D_2$   |
|---------------------|------------------|------------------|---------------|
|                     | 94924.92         | 94905.20         | 93970.3       |
| <i>X</i> = 79221.51 | 15703.41 (+0.01) | 15683.69 (-0.01) |               |
| <i>W</i> = 78952.24 | 15972.68 (-0.01) | 15952.96 (+0.01) |               |
| <i>Y</i> = 78946.24 | 15978.68 (-0.01) | 15958.96 (-0.01) | 15024.1 (0.0) |

This accounts for one line fewer than de Bruin's classification (a decidedly stronger line than its neighbours, and one which might well be unconnected with them) but demands one less term, so that on grounds of economy of assumptions, it is to be preferred. Furthermore, it agrees throughout with measured values of wave-length to within less than 0.004 Å, whereas de Bruin's classification involves errors of more than 0.1 Å in lines measured by Frerichs to the nearest thousandth of an angstrom. If the classification suggested here is the true one, there is no reason to suppose that the term *R* exists, and consequently the green coronal line remains unexplained. Further exact measurements of the oxygen lines in question would settle the point, and are much to be desired.

### The Oldoway Human Skeleton

WE are glad to find from Dr Leakey's letter in NATURE of May 14 that he is in agreement with us in regarding the Oldoway skeleton as an artificial burial, and regret that, in common with everyone else whom we have consulted in this matter, we interpreted his original letter in NATURE of Oct 24 to mean that it was naturally deposited without human agency in Bed 2.

With the recognition that it was buried by man, the discussion of its date rests on a series of hypotheses and presumptions which, even at their best, can never give a certainty comparable with that given by a natural deposition.

So far as can be discovered from published sources, the skeleton lay embedded in Bed 2 below a sloping surface dipping down toward a stream course. Bed 2 at the site of the interment was not, when Prof Reck began his work, covered by Bed 3, which had presumably formerly extended over it but had been removed by erosion. Dr Leakey now claims that the skeleton was buried in Bed 2 before Bed 3 was deposited over it. This involves the supposition that the deposition of the materials of Bed 2 took place in water so shallow that a bedding plane was at one time exposed to air and sufficiently dried to allow men to walk over and dig a grave in it.

We know of only one line of evidence which could give certainty of the occurrence of such a condition, and should be glad to hear Dr Leakey's reasons for believing that it has occurred.

Granting this fundamental postulate, we have to consider the evidence that the grave was not dug in comparatively modern times. Dr Leakey claims that at a time less than fifty years ago the site of the burial was covered by an extension of Bed 3, and that hence, unless the burial took place before Bed 3 was deposited, or less than fifty years ago when Bed 3 was removed, some material of Bed 3, which differs markedly in colour and texture from Bed 2, must have been included in the grave infilling.

Dr Leakey, however, has shown that some survey pegs inserted by Prof Reck in 1913 were still *in situ* in 1931, so that the rate of denudation is demonstrably slow. Thus Dr Leakey's estimate of fifty years implies that the natural surface above the grave of the Oldoway skeleton lay only a few inches below the base of Bed 3. It is clear that an estimate of so small a thickness could only be made if the surface of Bed 2 on which Bed 3 rests is exceptionally plane, and if an elaborate series of levels had been made at the time of the original discovery before the land surface was destroyed. We understand that in fact Bed 2 is merely represented by *remanié* materials in the neighbourhood of the skeleton. It is thus extremely doubtful if it would be possible to make any sufficiently accurate measurements to justify Dr Leakey's estimate of fifty years. But in any event, the rate of denudation under the conditions existing at Oldoway must vary so greatly from yard to yard, falling probably to nothing where there is any protection afforded by vegetation, that the period required could not be estimated even if the data as to thickness were established.

The photographs published by Prof Reck show that the whole of the upper and a good deal of the lateral surfaces of the skeleton were exposed during the excavation made for its removal, and it is hence probable that Prof Reck removed it and a pedestal of the rock on which it rested by the ordinary method of hardening and bandaging. It need scarcely be pointed out that the only material certainly of the grave infilling carried to Munich in this way is that

which is contained within the ribs and between the limbs and the trunk, and that this was the first earth to be thrown back again into the grave.

The material of Bed 3 as it exists in a *remanié* form in the neighbourhood of the grave seems to consist of small calcareous nodules of varying hardness stained red with ferric hydrate. It is quite conceivable that their colour might be materially altered by contact with a decaying body. If the thickness of Bed 3 penetrated in the grave was small in proportion to that of Bed 2, the admixture would be small in any case, and the whole of the materials of Bed 3 excavated might be so completely covered during removal by those of Bed 2 that when this soil was shovelled into the grave, it is possible that the whole of the Bed 3 materials might be included in the mound above the surface and none reach the bottom of the pit. Thus although the discovery of a single fragment of Bed 3 in the grave infilling would show that the grave was dug through this bed, the absence of such a fragment does *not* show that the pit did not pass through it.

It is evident that the grave infilling which remained in the block when it was sent to Munich only represents a small proportion of that which filled the whole grave, and as the skeleton was still undisturbed when Dr Leakey examined it in 1925, it is clear that the proportion of the total volume of the grave infilling which he saw was minute. It is, furthermore, a universal experience that the appearance of a mass of rock is greatly altered by the process of hardening and bandaging, and, as we have pointed out, mere proximity to a large decaying body often alters the character of a matrix. Thus we feel that Dr Leakey is rash in stating that there is no trace of Bed 3 in the grave infilling.

If Dr Leakey be held to have established that the grave of the Oldoway man was not dug through Bed 3, he has still to show that it cannot have been dug during the period which has elapsed since the removal of Bed 3 took place. We have already shown that his estimate of fifty years is a guess, owing to the lack of adequate data as to thickness and to the variable rate of denudation from place to place.

Dr Leakey's evidence that the bones of the skeleton seem to be as much mineralised as the others in Bed 2 is of no great value. The specimens now in the Natural History Museum from this bed vary immensely, from bones easily powdered between the fingers, to others which are hard and brittle. No one can ever say how long it takes any bone to reach any particular physical or chemical state.

The only other evidence which Dr Leakey advances is that the anatomical characters of the skeleton cannot be matched amongst the local natives. But we understand, though we have not seen their work, that Messrs Gieseler and Mollison, who have recently described the remains, point out resemblances to the Masai who still inhabit the district.

It is thus apparent that the evidence Dr Leakey has so far adduced in no way excludes the supposition that the Oldoway skeleton represents a burial of relatively recent date.

The remainder of Dr Leakey's letter in NATURE of May 14 has no relevance to the particular problem of the age of the Oldoway burial, which is the only one with which we are concerned.

### The Shedding of Certain Fibres in the Coat of the Lamb

In his letter<sup>1</sup> in *NATURE* on *Ovis astore*, Prof A F Barker discusses the shedding of certain fibres by domesticated sheep. As he points out, the shed fibres are usually regarded as representatives of the outer coat of wild sheep. The persistent fibres, of indeterminate growth, are looked upon as derivatives of the ancestral under-coat of wool. It is believed that the fibres of this under-coat, instead of ceasing to grow after a few weeks or months, and later being shed, have taken to maintaining their growth for a very much longer time, often probably throughout the natural lifetime of the animal.

While these generally accepted ideas concerning its ancestral history form the background of our thinking about the biology of the fleece, the present purpose is to point out the need for thinking of shedding and non-shedding in terms of physiology as well as phylogeny. In studies of the fibre types of the New Zealand Romney and their life histories, the attempt to explain the detailed observations made has led to speculations about differences in the activities of the follicles that determine whether a fibre ceases to grow and is succeeded by another, or whether the same fibre grows continuously. The present discussion is based mainly upon work on the region of the middle line of the back near the level of the last rib.

In the New Zealand Romney lamb the structural differences between the collection of birthcoat fibres that cease growing at about two months and those of persistent growth appear to be much less sharply defined than the differences between the fibres of the outer and the inner coats of wild sheep or of the Black-headed Persian<sup>2</sup>. In kempy lambs the biggest fibres present at birth are well-nigh certain to be shed, while many of the smaller types are sure to persist. In between come several types, covering a considerable range of characterisation, and taken together numerically important, that may or may not be shed. Which fibres are shed and which persist is clearly determined by orderly forces.

For many fibres it does appear that the balance may easily be tipped one way or the other towards shedding or persisting. In an earlier communication<sup>3</sup> it was stated that the proportion of sickle-fibres shed varies greatly from lamb to lamb. When many persistent sickle-fibres are present that resemble quite closely, in their apical structural details, some which are shed, it is a common thing to find some of these persistent sickle-fibres with a very marked thinning for half an inch or so below the point corresponding to the base of the shed fibres, while below this thinning the fibre becomes coarse again. Other persistent sickle-fibres, but little dissimilar apically from the last, continue comparatively coarse throughout what is evidently a critical time in the activities of the follicles of many sickle-fibres. It is believed that amongst fibres that will continue their growth for some weeks after birth, the earlier a fibre starts its development the greater its chance of ceasing to grow at about eight weeks, except in so far as the follicle is affected by the kind of birth check, a phenomenon to which reference was made in the earlier communication. It would appear that follicles which are well established before the birth check becomes powerful tend to shed their fibres, and that fibres grown in follicles founded just late enough to miss the force of the check are also more likely to be shed than those that have to face the intensity of the check at a very early stage of growth.

Wide variations from lamb to lamb are found in the proportion of shed and persistent fibres of several types, and it is possible to go a good way in generalis-

ing about the structural differences between shed and persistent fibres classified as of the same main type. The facts of the case seem to fall into line if we suppose simply that, in those follicles in which growth ceases for a time, fibre material has at some post-natal stage of development been elaborated at a greater rate than in those follicles where growth continues without interruption. In other words, if the follicle overworks, it is compelled to take a rest, and growth comes to a stop.

It is hoped shortly to publish the detailed evidence upon which this suggestion is based. Attempts are being made to test this explanation in various ways. The present purpose, however, is not to argue for the correctness of a particular working hypothesis, useful though it is proving. It is desired rather to show the kind of outlook upon shedding that results from a study of the details of structure and development of the lamb's coat.

The simple fact that mammalian hair grows only at the basal end invites fuller exploitation. Each fibre is an autographic record of a series of events in the follicle. Often enough portions of the curve traced by a fibre are suggestive of shorthand symbols. A better understanding of the code would enable us to decipher illuminating messages on many a biological question.

### Attack of Oxygen Molecules upon Highly Crystalline Graphite

THE accompanying photographs (Fig 1) illustrate an observation made while studying the oxidation of graphite. A thin flake of Ceylon graphite (99.9 per cent carbon) was oxidised during many hours at 900° C in a stream of oxygen at 1 mm pressure.

FIG 1—Crystalline graphite during oxidation ×140

(The product is about 50 per cent carbon dioxide and 50 per cent carbon monoxide.) Photomicrographs were taken at intervals, the two reproduced show the state of the flake when probably more than four-fifths of the original graphite had been oxidised away. In both, the flake is viewed, roughly, perpendicularly to the cleavage plane, A by light reflected from this plane, B by transmitted light.

There are two interesting features (a) The power of brilliant reflection at the appropriate angle from the

surface of the flake remains unimpaired throughout the oxidation, there is no pitting of this surface. Apparently carbon atoms are removed layer by layer. (b) The holes which eventually appear in the flake have a well-defined hexagonal form, which they retain as they grow, although when they reach the size shown, the corners begin to round off a little, when smaller, the hexagon appeared very regular. (Unfortunately, the reproductions appear more distorted than the original photographs, themselves imperfect.) The shadows round the flake in Fig 1, B, are caused by semi-opaque patches in the silica pan carrying the flake. It will be noticed that corresponding sides of the two clearly formed hexagons are parallel.

Possibly the formation of these holes is caused in the first place by the presence of minute inclusions of impurity, such as iron or an alkali metal salt, which would catalyse the oxidation of the carbon with which it is in contact. But the subsequent growth of the hexagons provides a manifestation of the influence of lattice symmetry upon the course of a chemical reaction. It seems to us that the points (a) and (b) are of interest in connexion with the mechanism of the oxidation of graphite.

#### Oxidation of Strychnine

I HAVE been studying the action of oxidising agents on strychnine for some time. Leuchs<sup>1</sup> stated that he had obtained an acid with the formula  $C_{21}H_{22}O_4N_2$  from strychnidine by means of oxidation with chromic acid. The acid is stated to crystallise from water in brown needles that do not melt up to 320°, and are nearly insoluble in alcohol and acetone, but readily soluble in ammonia, *N*-hydrochloric acid, and acetic acid. The acid in question gives crystalline precipitates in needles and prisms with nitric and hydrobromic acids, and amorphous precipitates with hydriodic and perchloric acids, which then become crystalline scales.

It appears that Leuchs<sup>2</sup> obtained this same compound by oxidising tetra-hydro-strychnine with large quantities of chromic acid in a carrier acidified with sulphuric acid, and Wieland admits that the high melting point of this compound shows<sup>3</sup> that the acid  $C_{21}H_{22}O_4N_2$  is a diphenyl derivate, to which he attributes, with more probability, the formula of  $C_{42}H_{42}N_4O_8$ .<sup>4</sup>

I would like to point out that by oxidising strychnine with chromic acid in a carrier acidified with acetic acid, I have obtained a crystalline compound in very shiny prisms, which melt at 309°-310°, and are soluble in alcohol and chymol when hot, but practically insoluble in water and all organic solvents, especially chloroform.

The reaction of this compound is neutral with litmus paper, and it gives strongly the colour reactions of strychnine. The product in question is obtained with several processes, and analysis gave the following results.

Microscopic analysis gave the following percentages

Carbon— 68.77, 68.69, 69.07, 68.58  
Hydrogen— 5.68, 5.65, 5.61, 5.53  
Nitrogen— 7.31, 7.38, 7.85, 7.75

Macroscopic analysis gave the following percentages

Carbon— 68.99, 68.86  
Hydrogen— 5.75, 5.88  
Nitrogen— 7.40

These results agree both with a formula of

No. 3268, Vol. 129]

$C_{21}H_{20}N_2O_4$  and that of  $C_{42}H_{42}N_4O_8$ , and they seem to me to be interesting, since I am of the opinion that this is the first case in which a product has been obtained from the oxidation of strychnine that has the same number of atoms of carbon as that of the alkaloid itself.

Fuller details regarding this question will be sent later to the *Gazzetta Chimica Italiana*.

#### The NO<sub>3</sub> Frequency in Organic Nitrates

THE characteristic inactive frequency at 9.5  $\mu$ , corresponding to a wave-number shift of 1050  $cm^{-1}$ , while it appears as a strong Raman line in the scattered spectrum of all inorganic nitrates examined both as crystals and in solutions, is not represented at all in the Raman effect of the organic nitrates. This is probably due to the influence of the CH group on the oscillations of the NO<sub>3</sub> ion. However, in alcoholic solutions of these organic nitrates this line comes out significantly, the intensity of the line depending upon the solvent used and also upon the concentration of the solution.

In the scattered spectrum of methyl nitrate (pure liquid), in addition to the CH frequencies, the observed Raman lines correspond to  $\nu_5$  583, 662, 866, and 1290, all of which are quite strong. These shifts, which are simple in methyl nitrate, are each split up into two or more components in the spectra of the higher alkyl nitrates, and also there is a considerable change in their intensities. In a twenty per cent solution of methyl nitrate in methyl alcohol none of these lines comes out, but instead we get a strong line at  $\nu_{23}$  665  $cm^{-1}$  which is excited by  $\lambda$  4047 of the mercury arc and corresponds to a shift of 1040. An equimolecular solution of amyl nitrate in amyl alcohol shows this shift only as a very faint line.

In this connexion it may be mentioned that the dielectric constant of methyl alcohol is very high, coming next to water, with a value 35, while for amyl alcohol it is only 16. We have studied the behaviour of this shift with dilution and there is a general tendency for the line to increase in intensity as the dilution increases up to a certain limit. A more detailed account of the investigation appears elsewhere.

#### A Displacement in the N Lines of Tungsten and Tantalum

WE have recently conducted some experiments on the characteristic radiations of various elements in the extreme soft X-ray region. Spectra have been obtained with the aid of a vacuum spectrograph employing a plane Siegbahn grating in the grazing incidence setting. Using a water-cooled anti-cathode, on to which tungsten was sputtered from the hot filament of the X-ray tube, we have obtained lines at 55.58 and 58.42 Å. Thibaud and Soltan<sup>1</sup> have previously obtained wave-lengths of 56.0 and 59.1 Å, while Prins,<sup>2</sup> who, in addition to using this procedure, has apparently employed a water-cooled tungsten anti-cathode, has recently published values of 55.7 and 58.4 Å, with which our results are in good accord.

Using an anti-cathode of tungsten sheet, allowed to become incandescent, we find that the lines are displaced. The wave-lengths are now 55.29 and 58.09 Å respectively. This represents an increase in the corresponding energies of 1.2 electron volts for each line.

The short wave-length line (55.58 Å) may be safely attributed to a transition ( $O_{IIIII}$  to  $N_{IV}$ ) and the long wave-length line (58.42 Å) to ( $O_{III}$  to  $N_V$ ). The energy shift obtained when the tungsten is hot being the same for both lines, it is natural to suppose that it is due to a change in the common initial state. This is to be expected, since the final  $N$  levels are relatively deep within the atom. We thus arrive at the conclusion that the  $O_{IIIII}$  level is 1.2 volts deeper for the cold tungsten than for the hot.

The shift of the  $O_{IIIII}$  level may be explained either by assuming that the crystal structure is different in the two cases, or by supposing that there is a difference in the chemical state. The evidence points to the latter explanation being the correct one, the hot tungsten measurements being due to tungsten and the cold measurements being due to oxidised tungsten.

Experiments with tantalum (73) indicate for the  $O_{II}$  level a movement of 3.2 volts in the same direction as that observed for tungsten (74). Curiously enough, there seems to be little shift of the  $O_{III}$  level.

#### Overseas Forestry Officers and Home Appointments

THE issue of NATURE for April 9 included an advertisement of a vacancy for an assistant in the Department of Forestry of one of the universities. The advertisement stated that experience in a Government forest service was very desirable, but the period of only one month allowed for the submission of applications practically precluded the candidature of many officers of the overseas forest services. I think that there must be many able and experienced forest officers in those services who would welcome the opportunity of applying for a vacancy of the nature advertised, and would suggest that universities and institutions having similar vacancies to fill would be able to choose from a much wider field of applicants if longer notice were given.

#### Chemical Warfare and Disarmament

WE should all be grateful for the eminently sane leader on this subject in NATURE of June 4. The real objection to the use of toxic vapours is that they are too humane. Nearly all the injured soldiers return to the active list after a few months, with the result that the war is prolonged. The use of feeble weapons does not really diminish the number or the seriousness of casualties in war. Supposing that the combatants in 1914-18 had been armed only with swords and daggers, but that the means of transport and therefore the numbers had remained the same, the slaughter would have been much worse, because in every battle the losing side would have been practically annihilated in the hand-to-hand conflict.

I personally am sceptical about the fearful mortality

No 3268, Vol. 129]

predicted by Prof. Langevin and others as the result of the release of gas bombs over our large cities. Every day hundreds of tons of carbon monoxide are given off by motor cars in our streets, but no one is killed, and it is not certain even that our health is affected. The toxic vapours used in warfare are much more potent than carbon monoxide and are heavier than air, but I am not convinced that they would have a worse effect than an equal quantity of high explosive, which, however, would be sufficiently disastrous if used in really large quantities.

As regards Dr. Delisle Burns's letter, he might with advantage study that of Prof. Cockerell on "Internationalism and Science" also contained in NATURE of June 4. We are all in danger of mistaking "feeling" for "thought". The problem of international peace, commercial as well as military, is mainly one of mass psychology. Will not the psychologists give us a lead?

#### Light and Sexual Periodicity

I AM much interested by Mr. L. J. Llewellyn's letter under this heading,<sup>1</sup> having long wished to obtain information on the effect of absence of sunlight in arctic regions. Eventually everything is traceable to sunlight, but may not the immediate cause, during the dark period, of sexual inefficiency, be the lack of vitamins in the winter food? Have they any vegetable food? It has been reported that sterilised milk causes infertility in male rats. We are now learning that our own food, during the low-temperature, low-light period, is greatly deficient in quality—to what extent we have as yet no idea. Animal health and activity are at their lowest at this period. Our reaction to sunlight is probably dependent upon the existence within us of special materials derived from our vegetable food. The sun appears to have no particular recuperative antirachitic value in the east, where the quality of food is at its lowest, owing to soil starvation. A closer study of dietaries is needed in this connexion.

#### Eland-Ox Hybrid

DR. WARREN'S<sup>1</sup> interesting cow-eland hybrid is the sixth mammalian intergeneric cross of which I can find a record. The polecat and ferret, which hybridise have been placed in different genera, but with very doubtful propriety. Apart from these, the other crosses all involve *Bos*. *Bos taurus* ♀ has given hybrids with *Poephagus grunniens*, *Bison bison*, and *Bison bonasus*, and *Bos indicus* ♀ with *Bibos frontalis* and *Bibos sondanus*. In every case the male hybrids were sterile and the females fertile. There was also a significant excess of females where the sex ratio was recorded. I have summarised the literature elsewhere.<sup>2</sup> It is to be hoped that if Dr. Warren's male hybrid calf proves sterile, as seems likely, its testes will be preserved for cytological examination, and the attempt made to breed female hybrids.

## Research Items

**Nicobarese Burial Customs**—Some observations of hitherto unrecorded ossuary customs practised on the islands of Bompoka and Teressa in the southern area of the Nicobars are recorded in *Man* for May by Mr C J Bonnington. A man of Teressa is buried with his head pointing west as he lies on his back. A soul figure in the form of a post is placed over the grave, which is covered with cloth and the general belongings of the deceased, as well as the head-dress worn by his wife on festive occasions and the skulls of the pigs killed by him, which had hung in his hut as ornaments during his lifetime. In the case of individuals without near relatives, the body is placed as soon as possible in a half-canoe. This is then hung by fibre ropes on a pole supported by two trees in the communal ossuary, which is situated in jungle by the seashore. The body is left to rot, and as the canoe breaks up, the bones fall to the ground to mingle with those of past generations. With burials the remains are disinterred after some months, and if the deceased has been a revered personage, the skull is placed in a life-sized wooden body, which is hollow and has a door in the back through which the remaining bones are introduced. This figure is kept in the hut of the nearest relative. The bones of less important people are kept in little log coffins. These receptacles are kept stacked around the walls of the hut. In one instance observed the figure has a human skull for the head. This was the mother of the present headman, who had been a witch doctor. At meal times food is placed before the wooden figures for the spirits who dwell therein. After a period of sometimes ten years, in which the pig stock of the community is considerably increased, a large feast is held and the bones of the less important people are thrown into the common ossuary. A parallel is cited from Assam.

**The Eskimo of Alaska**—The annual report of the Smithsonian Institution of Washington (*Pub* 3134) on its investigations and field work in 1931 includes an account of investigations which bear on the prehistory of the Eskimo and throw light on a number of points which have hitherto been obscure. During the summer season Dr Aleš Hrdlička was engaged in the collection of skeletal remains and objects of material culture from prehistoric sites on the Nushagak River and watershed. Anthropometric measurements of the living were also taken. One site on Uyak Bay which was investigated is, it would appear, the oldest yet discovered in the far north. It is concluded that the natives of the Nushagak River and watershed are definitely all Eskimo, belonging to the south-western type, and are identical with the Kuskokwim and the neighbouring Tundra Eskimo from whom they are largely, if not entirely, derived. It is evident that the peninsula was a sieve for movements of the people from the north southwards, and that all comers from the Bering Sea and north-western Asia would naturally come along the western coast, cross by the passes, carrying their skin boats over the few rapids and portages, and find themselves facing Kodiak Island or Cook Inlet, whence the way would be open to the north-west coast and the rest of the continent. The peopling of America, therefore, took place not through Alaska but along its western coast and through the peninsula.

**Life History of a Fresh-water Snail**—An investigation of the growth, longevity, and fecundity of the fresh-water snail, *Lymnaea columella*, a species easily reared in aquaria, a free breeder which reaches

maturity rapidly, has been carried out by Joshua L. Baily in the Biological Research Institute of Johns Hopkins University (*Biol. General*, Bd 7, 1931, p 407). The maximum duration of life in the specimens which reached maturity ranged from 130 to 139 days, and the youngest mature individual died at 72 days old. In the latter case the number of eggs laid was 64, in the former the numbers varied from 427 to 693, but 725 eggs were laid by an individual which died at 126 days. It is probably true, nevertheless, that total egg-production is directly associated with duration of life and with limiting shell size, and that duration of life is inversely associated with maximum growth rate. Growth itself, as measured by aperture length, is orderly and regular, and can be represented by a logistic curve, another addition to the number of forms in which individual growth can be thus described. The evidence, although suggestive, is less definite regarding the relation between duration of life and limiting shell size, and between the size of a clutch of eggs and limiting shell size, both of which seem to be directly associated.

**Diving Powers of the Pelagic Insect, *Halobates***—*Halobates*, like some related fresh-water Hemiptera, skims upon the surface film, but whether it can break the surface and dive below, for example to avoid storms, has been in dispute. Dr H C Delsman, contrary to the statements in the "Cambridge Natural History", wrote in 1926 (*Treubia*, vol 8, p 384), "*Halobates* cannot dive. When frightened it always takes recourse to rapid flight." Now G M Henry states that he has seen an Indian Ocean species, *H. flaviventris*, at close quarters while he was bathing, and that there can be no doubt that this species, at any rate, dives freely when disturbed, and reappears on the surface (*Spolia Zeylanica*, vol 16, p 353, March 1923). The actual dive was so quick that a *Halobates* scudding along before the observer appeared merely to vanish suddenly. Under water, however, the movements of the insect were impeded and it could be seen for a fraction of a second before it broke the surface-film on returning to the surface. It would be interesting to know by what means, since apparently they do not indulge in high diving, the insects are able to overcome the surface tension.

**Californian Fisheries**—Recent researches in fisheries are embodied in three Bulletins (Nos 28, 29, and 30) of the Division of Fish and Game of California. The first of these (28) is a most useful guide, entitled "Handbook of Common Commercial and Game Fishes of California", by Lionel A Walford. This work, primarily intended for the use of those with little or no scientific knowledge, aims at establishing official common names of those Californian fishes which are handled commercially or are of special interest to fishermen or dealers. It was enacted in 1919 in a State law that "the Fish and Game Commission shall have the power to decide what is the common usage name of any variety." Thus the names given are official. We find here clear illustrations of anatomical terms, a key to the identification of certain fishes, and descriptions and illustrations of the fishes, each occupying a page, the figures being taken from excellent photographs. The common and scientific name, relationship, distinguishing characters, distribution, fishing season, importance, fishing gear are given in every case. Besides the true fishes some commercial invertebrates are also described. An appendix at the end includes a glossary of names of the fishing gear used in California, and notes on the meaning of

scientific names. The second bulletin (29) is on the "Striped Bass of California (*Roccus lineatus*)" by Eugene C. Scofield. This fish was only brought to California in 1879 from the Atlantic, and ten years after was already a commercial success. The report describes methods of fishing, life history, and details of the commercial catches. The third bulletin (30) is by the staff of the Bureau of Commercial Fisheries on the "Commercial Fish Catch of California for the Year 1929."

**The Discovery Nebaliacea**—Before the *Discovery* Expedition collected in the South Atlantic seven specimens of *Nebaliopsis*, this genus was known from four specimens, one of which was merely named as "a new *Nebalia*" and was lost. The two original specimens were collected by the *Challenger* Expedition and another by the *Valdivia* Expedition. Of the seven *Discovery* specimens, six were crushed or fragmentary, but one was complete and undistorted. That this species lives at great depths is confirmed by the collection of one example at a depth of about  $1\frac{1}{2}$  miles. By studying the undistorted example, Prof. H. Graham Cannon (*Discovery Reports*, 3, 199-222, 1931) has been able to ascertain the normal arrangement of the limbs and to deduce the mode of feeding. After describing the limbs and their movements, he remarks that the trunk limbs, which have a very thin cuticle, depend to a great extent on the blood-pressure for their turgidity, and differ markedly from the powerful swimming pleopods, which have an abundant musculature and a thick cuticle. The deduced movements of the trunk limbs would result in a forward current in the mid-ventral line, laden with food particles, which are retained by the setæ borne by the inner margins of the trunk limbs, from which they are scraped off and passed forwards by the mandibular palps to the mouth. *Nebaliopsis* is the most specialised of the Nebaliacea, and is regarded as having evolved from a planktonic *Nebalia*. One specimen of *Nebaliella extrema* was found by the *Discovery* in the Palmer Archipelago, and the examination of its trunk limbs shows that they are arranged as in *Nebalia* and have a corresponding setal armature. Epipodites are absent, but each of the proportionally larger exopodites has taken the place of the combined exopodite plus epipodite of *Nebalia*. Interesting observations on the rostrum and the eye-stalks—here thin-scythe-like plates—suggest their function in ploughing through the mud and in guarding the anterior opening of the carapace against choking by mud as the animal pushes itself forward by the spinose third and fourth segments of the antennæ. Eight specimens of *Nebalia longicornis* were collected in South Georgia, the Falkland Islands, and near Simon's Town, South Africa.

**Plant Immunity**—A very interesting point of view has stimulated the investigations of Dr. A. C. Leeman into plant immunity ("The Problem of Active Plant Immunity", by A. C. Leeman *Zent. Bakteriologie*, Abt. II, Bd. 85, pp. 360-376, 1932). It is recognised that antibody production and related phenomena, as they are associated with the animal body, play no direct part in the immunity of a plant. But the author has shown that certain extracts and organic substances play a considerable part in stimulating the resistance of a plant to attack by a fungus disease. The substances, when added to the soil, are harmless to the parasite, but become detrimental when taken into a plant and incorporated with its protoplasm. Secretions and extracts of micro-organisms, and various enzymes, have been found to reduce the damage caused by the parasitic fungus *Helminthosporium sativum*. The interaction of micro-organisms has also been studied as a means of disease control.

**X-Ray Standards**—The preliminary report on the comparison of the X-ray standards of the United States, Great Britain, Germany, and France made by Dr. L. S. Taylor of the Bureau of Standards to the Third International Congress on Radiology in July has been issued in full (*J. Research*, January). The comparisons were made by means of a portable guarded field ionisation chamber taken to each laboratory. The agreement between the standards is much better than is required for present-day practice. The joint recommendations of the Bureau of Standards, the National Physical Laboratory, the Reichsanstalt, and the Hôpital St. Antoine as to the open-air ionisation chambers to be used in standardisation are given in full, and include the use of a focal spot less than 0.8 cm. in diameter, the shielding of the ionisation chamber from all radiation except that from the face of the target, the use of an aperture of the ionisation chamber not much smaller than 0.8 cm. diameter, with the collector electrode as near as possible to the aperture, and the measurement of the current by a null method if possible.

**Photoelectric Cells**—An article by C. J. Smithells, of the General Electric Co. (*Chemistry and Industry*, May 20), gives an account of the applications of photoelectric cells in chemical engineering, and incidentally of the modern types of such cells. There are four main types, namely, the selenium cell (with which may be classed the more modern thalofide cell, in which thallium oxysulphide is the light-sensitive material), the alkali metal cell, the copper oxide rectifier, and the electrolytic cell. The selenium and thalofide cells, which have the greatest sensitivity but are not suited for accurate measurement, depend on the decrease in ohmic resistance of the material on exposure to light. The alkali metal cell has a cathode plate covered with alkali metal, from which electrons are emitted on exposure to light, the current being proportional to the amount of light. The copper oxide rectifier consists of a layer of cuprous oxide on copper, and if a gauze is placed on the oxide layer, a current will flow between the gauze and the copper when light falls on the oxide through the gauze. No external e.m.f. need be applied. A similar effect is obtained with selenium on lead. This is the basis of the German Sperrschicht cell. The electrolytic cells make use of the Becquerel effect, the development of an e.m.f. by substances such as cuprous oxide in a solution of potassium sulphate on illumination, a current flowing between this electrode and another one, for example, platinum, in the solution. The advantages and disadvantages of all these types of cell are discussed, and their uses explained, in the article. The very small currents from the cells are amplified by means of thermionic valves, and with this type of apparatus the alkali metal photoelectric cell is most suitable. An even better arrangement than a thermionic valve and relay is a gas-filled relay, sometimes called a thyatron.

**Internal Perturbations in Atoms**—A paper has been published by A. G. Shenstone and H. N. Russell in the first February number of the *Physical Review*, on perturbed series in line spectra, which may lead to a rapid development of the analysis of some spectra which have hitherto proved intractable. It is based upon the idea of resonance in quantum mechanics. If an atom has two states of similar quantum properties, and comparable energy, these may affect each other in such a way that their separate identity partly fails, and they give rise to two states, each of which has an energy different from that which it would normally possess. A quantitative expression for this, not unlike an anomalous dispersion formula, was given two

years ago by R. M. Langer, and it is this which has now been applied to a large number of actual spectra. The perturbations are remarkably common, occurring in such well-known spectra as those of neutral calcium and neutral copper, and can now be detected readily by a graphical method which has been elaborated. In addition, where both of the interacting states have been wrongly included in a single series, this can be recognised; strictly speaking, it is not that one state is associated with one series and the second with another, but that each state belongs to both, but it is often convenient to make the admittedly rather arbitrary distinction. In the present paper, the spectra Ca I, Ba I, Hg I, Cu I, and Al II are discussed in some detail, and a number of corrections and additions are made to the older analyses of these.

**Sal Alembroth.**—In the *Festschrift für Georg Jacob zum siebzigsten Geburtstag*, Prof. J. Ruska has an article (pp. 234-240) on *Sal Alembroth*. This term is at present applied to a compound  $\text{HgCl}_2 \cdot 2\text{NH}_4\text{Cl} \cdot \text{H}_2\text{O}$  (probably mixed with  $\text{NH}_4\text{Cl}$ ), and has been used in the same sense since the end of the seventeenth century, if not earlier. In medieval times, however, the name appears to have been given to various other substances, for example, one made "ex septem herbarum succis", and there is little doubt that, like many other alchemical terms, it is a transcription of some Arabic name. Prof. Ruska considers the various possibilities that suggest themselves, and rejects the tempting etymology from the Greek *ἀμβροτος*, since this word is not found in Greek alchemy. The derivation from *al-mabrûk*, "the blessed", which on general grounds appears most likely, is rendered improbable by the fact that no particular compound in Arabic alchemy appears to have been known as *milh mabrûk*, *sal benedictus*. A last possibility is that *alembroth* is a mistranscription of *alṭabarzad*, a Persian word meaning scissile: such Persian terms, frequent in

Muslim alchemical books, would often be unintelligible to a western translator, and would consequently be particularly liable to corruption.

**Safety Glass.**—Mr. J. Wilson, of the Triplex Glass Co., has given an interesting account (*J. Soc. Glass Tech.*, March 1932) of the history, manufacture, and testing of safety glass. The first successful safety glass, Triplex glass, was invented by Edouard Benedictus, although the underlying idea had been patented in 1905 by Wood. Practically all forms of laminated safety glass at present in commercial use consist of two sheets of glass with an interposed sheet of either celluloid or cellulose acetate. In the process used in making safety glass, the clean dry glass is first coated with an extremely thin film of gelatin and re-dried, although some makers omit the gelatin treatment. The glasses and celluloid or cellulose acetate sheet are then assembled, either by vacuum treatment in bags, the lamination being completed by hot water under pressure on the outside of the bag, or else by the use of an inert assembly liquid sprayed over the plates, followed by rolling and pressing, the latter being accomplished in autoclaves in the modern process. The edges are then usually sealed by removing a short strip of the celluloid round the edge and filling with hot bitumen. The glass is subjected to tests: for brittleness and adhesion by dropping a weight on a test piece, for blisters and bubbles by boiling with water, for efficiency of sealing by exposure to moist air, and for discoloration by exposure to ultra-violet light. No commercial safety glass is absolutely fast to light, but the best acetate glasses are better in this respect than the best nitrate glasses. Polymerised resins, such as polyacrylic acid esters, seem to offer advantages over celluloid or cellulose acetate, as they are fast to light and do not require sealing at the edges, although at present there are manufacturing difficulties in their use.

### Astronomical Topics

**The Lunar Bright Rays.**—Messrs. Buell and Stewart have carried out an interesting experiment to test a theory of the nature of the systems of bright rays that surround many lunar craters (*Pop. Ast.*, May). It is well known that the rays are best seen at full moon; this applies to all parts of the disc, both those where the sun is high and where it is low. The suggestion is made that they are conspicuous when the angle between the earth and sun as seen from the moon is small, for the reason that at such a time shadows on the moon are practically absent. The authors think that the rays are due to some whitish powder filling up the interstices between larger, darker lumps of matter. At full moon we receive the full light from the powder, but at other times a large proportion of the powder is in the shadow of the lumps.

An artificial surface was prepared by crushing basalt into large granules, and pouring finely powdered basalt into the interstices; the powder appears much whiter than the granules. The surface was photographed at different angles of light-incidence, and it was found that a close correspondence existed between the results and the phenomena of the lunar rays. The authors' explanation of the rays is that large lumps of basalt (or some similar substance) were expelled from the craters, either by volcanic explosion or meteoric impact, and that the shock of striking the ground caused portions of these lumps to be pulverised, the powder filling the interstices between the lumps. The theory seems well worthy of consideration as a possible ex-

planation of the perplexing phenomena presented by the rays.

**Spectrum of XX Ophiuchi.**—The spectrum of this 'iron star' is of very unusual character and shows, in addition, remarkable variations. It is described in detail by P. W. Merrill (*Astrophys. J.*, 75, 133), who studied it during the years 1921-1931 with the Mount Wilson 100-inch reflector. The star is classed at Harvard as *Bep*, but at the beginning of the above period it was marked by strong, sharp emission lines of H and Fe II, to which were added in 1925 numerous wide displaced absorption lines. The lines of Ti II were prominent amongst the latter, and all showed variations of intensity, width, and displacement. The mean displacement of the bright H lines differed by 30 km./sec. from those of other lines. Another interesting feature is that although the star is a variable (of the *R Coronae* type), many considerable changes in spectrum occurred during a period of constant brightness, whereas a change of one magnitude in the brightness was accompanied by no appreciable change of spectrum. Some analogies to the spectra of novæ suggest a tentative explanation based on a modification of Halm's hypothesis of an expanding shell surrounding the star. The author suggests that the narrow bright lines and wide absorption lines (exactly the reverse of the conditions found in novæ) may be explained by assuming a thin shell close to the photosphere, in which a large area would give rise to the absorption spectrum and only a fraction at each limb would cause the emission lines.

### Presidents of the Royal Society and their Portraits

A PORTRAIT of Lord Rutherford, who was president of the Royal Society for the five-year term 1925-30, was formally handed over on June 9, on behalf of subscribers, to the keeping of the Society for inclusion in its portrait collection of those fellows who have occupied the presidential chair. The present example is by that facile and distinguished artist, Mr. Oswald Birley. As is generally known, Lord Rutherford was born at Nelson, New Zealand; Mr. Birley was born at Auckland, New Zealand, while both are alumni of Trinity College, Cambridge.

There is a number of such portraits of past presidents in the possession and care of the Royal Society. Unfortunately, the list is not a complete one. Regrettable gaps occur both early and late in the Society's history, but during the last half-century there has been a movement in favour of obtaining portraits of all presidents.

In the olden days a spacious canvas depicted the face, attitude, and figure of the subject through the whole-length or three-quarter mode, a representation which, to be venturesome and paraphrase Carlyle, was what a "faithful human creature" saw of a face and figure "with *his* eyes, and which I can never see with *mine*". Modern practice prefers, for various and doubtless satisfactory reasons, a smaller canvas. This involves, however, some monotony of presentation, taken together.

In those olden days alluded to, many of the portraits had divers places of abode; some were at Gresham College, in the City, thence to Crane Court, thence to Somerset House, migrating westward later on. Moreover, in those times personal gift by the president was generally observed. Lord Brouncker, the first president, who was in office for fifteen years, worthily began in this way. It may be hoped that at some future date a descriptive catalogue of all the portraits will be issued, supplementary to the present lists of portraits, with their painters and donors.

We print below the names of past presidents of the Society, with notes on some of them which are of interest in the present connexion, and with the name of the artist and donor in brackets, where portraits are in the possession of the Royal Society.

Viscount Brouncker (1662-77). There is a portrait of him in the National Gallery. It was Brouncker who signed a licence for the issue of Malpighi's "History of the Silke Worme" (1669). (Sir Peter Lely—president.)

Sir Joseph Williamson (1677-1680). Queen's College, Oxford, has a three-quarters length portrait; Williamson was educated there and was a considerable benefactor of the College. (Sir Godfrey Kneller—president.)

Sir Christopher Wren (1680-82). (Sir Godfrey Kneller—Stephen Wren.)

Sir John Hoskyns (1682-83). No portrait. Long on the council, with Wilkins, Evelyn, and Moray, amongst others. There is a three-quarters portrait of him at Corpus Christi College, Cambridge, in the ownership of a descendant.

Sir Cyril Wyche (1683-84). No portrait.

Samuel Pepys (1684-86). The "Principia" was ordered to be printed on Pepys' *imprimatur*. (Sir Godfrey Kneller—president.)

Earl of Carbery (1686-89). No portrait.

Earl of Pembroke (1689-90). No portrait.

Sir Robert Southwell (1690-95). (Sir Godfrey Kneller—president.)

Charles Montagu (afterwards Earl of Halifax) (1695-1698). No portrait.

Lord Chancellor Somers (1698-1703); painted in judicial robes of office. (Sir Godfrey Kneller—Sir Joseph Jekyll.)

Sir Isaac Newton (1703-27). The Society possesses three portraits. The chief is that by J. Vanderbank, painted in 1726, which hangs in the meeting room over the presidential chair, and was presented by Mr. C. B. Vignoles in 1841. Like the Vanderbank

LORD RUTHERFORD OF NELSON. From the portrait by Mr. Oswald Birley.

in the National Gallery, the subject is depicted seated. Newton himself presented a portrait in 1717, by Charles Jervas, sometime a pupil of Kneller [For the third portrait see below, Martin Folkes]

Sir Hans Sloane (1727-41) (Sir Godfrey Kneller—Sir Hans Sloane, 1716, after the close of his secretaryship)

Martin Folkes (1741-52) In addition to his own portrait, Folkes gave the Society a choice portrait of Francis Bacon, also one of Newton, signed by Vanderbank. Folkes was also finely delineated by Thomas Hudson, almost whole-length, seated in the presidential chair, the mace in the picture. This portrait is not at the Royal Society (William Hogarth—president)

Earl of Macclesfield (1752-64) (Thomas Hudson—president)

Earl of Morton (1764 to Oct 12, 1768) No portrait  
Sir James Burrow (Oct 27, 1768, to Nov 30, 1768, and July 2, 1772-Nov 30, 1772) This fine portrait shows him three-quarters length, in velvet surtout, with neckcloth, seated near a table, on which the left arm is resting (J. B. Van Loo—president)

James West (1768-July 2, 1772) No portrait.

Sir John Pringle (1772-78), the "Father of Military Hygiene" (Sir Joshua Reynolds—president)

Sir Joseph Banks (1778-June 19, 1820) Almost whole-length, seated in the presidential chair, in full panoply of the insignia of the Order of the Bath, with the mace and a silver-gilt inkstand, showing upright quills. Probably the portrait of him in the British Museum, by Sir Thomas Lawrence, would receive preference, where the accessories are not so oppressively obvious in the scheme (Thomas Phillips—executors of Don José de Mendoza Rios)

W. H. Wollaston (June 29, 1820-Nov 30, 1820), one of the seventeen children of a clergyman (J. Jackson—president's family)

Sir Humphry Davy (1820-27), almost whole-length, standing, facing spectator (Sir Thomas Lawrence—Lady Davy, in 1829)

Davies Gilbert (1827-30). (Thomas Phillips—president)

H. R. H. the Duke of Sussex (1830-38) During his tenure of office he constantly presided at meetings of the Council and Society (Thomas Phillips—president)

Marquess of Northampton (1838-48) (Thomas Phillips—president)

Earl of Rosse (1848-54) (J. Catterson Smith—president, in 1860)

Lord Wrottesley (1854-58) No portrait

Sir Benjamin C. Brodie (1858-61), like Wollaston, Brodie was one of the seventeen children of a clergyman (After G. F. Watts—Sir B. Brodie, in 1873)

General Sir E. Sabine (1861-71) (Stephen Pearce—Mrs Sabine)

Sir George Airy (1871-73) No portrait

Sir Joseph Hooker (1873-78) (Hon. John Collier—subscribers, 1881)

William Spottiswoode (1878-June 27, 1883) (Hon. John Collier—subscribers, 1885)

Thomas H. Huxley (July 5, 1883-85) No portrait.

Sir Gabriel Stokes (1885-90) (Hubert von Herkomer—subscribers, 1891)

Lord Kelvin (1890-95), almost whole-figure, and seated in a characteristic attitude, familiar to contemporaries (Sir W. Q. Orchardson—subscribers, 1899)

Lord Lister (1895-1900) Almost whole-figure. Mr. Oulless painted the masterly portrait of Darwin, etched by Paul Rajon (Mr. W. W. Oulless (copy)—purchased)

Sir William Huggins (1900-5), depicted seated in presidential chair (Hon. John Collier—subscribers, 1905)

Lord Rayleigh (1905-8) Almost whole-figure, seated. As in the portrait of Lord Kelvin, the attitude is characteristic, and familiar to his contemporaries (Sir George Reid—subscribers, 1903)

Sir Archibald Geikie (1908-13) (Mr. Reginald Eve—subscribers, 1914)

Sir William Crookes (1913-15) (Mr. E. A. Walton—subscribers)

Sir J. J. Thomson (1915-20) (Mr. G. Fiddes Watt—subscribers, 1922)

Sir Charles Sherrington (1920-25) Mr. Reginald Eve—subscribers, 1928)

Lord Rutherford of Nelson (1925-30) Three-quarters length, in academical robes, standing, right hand on hip, left hand resting on books below, near radium emanation apparatus (Mr. Oswald Birley—subscribers)

### The Film in National Life

THE report of the inquiry conducted by the Commission on Educational and Cultural Films has just been issued under this title. It makes a substantial book of 204 pages, and is published at the very low price of 1s net (London: George Allen and Unwin, Ltd.). The Commission was set up in 1929 as a result of a conference representing some hundred educational and scientific organisations. Its field of study included methods of improving films and extending their use for educational and cultural purposes, raising the standard of public appreciation of films, and establishing a permanent central organisation for such purposes. The Commission has since received influential support, and four interim reports have been issued. Its final recommendation is "That a National Film Institute be set up in Great Britain, financed in part by public funds and incorporated under Royal Charter." It is pointed out that the chief countries of the world all possess such organisations, which vary in scope, but in no cases are concerned with censorship. An important place is assigned to the film in national life in Austria, Germany, Italy, Japan, Russia, and the United States.

The magnitude of the film industry needs no com-

ment. It is estimated that there are in the world more than 60,000 cinema theatres, about half of which are wired for sound. About 85,000 people are employed by the State in the cinema industry in the U.S.S.R. alone, where the film doubtless serves as an exceedingly powerful instrument for influencing public opinion.

Films have already proved their value in medicine, in nature study and botany, in technical education, and in demonstrating industrial processes. Their application for conveying instruction on agricultural matters is specially noteworthy. Thus in the United States, films of this nature have been shown to more than twenty million farmers, and it is estimated that in Italy five to six million people saw the film entitled "The Wheat Campaign", prepared by the National Film Institute, Luce. The inestimable value of the film for recording history is evident. The official War films illustrated possibilities in this direction. Films have likewise been used in connexion with mountaineering adventures, for the study of racial subjects, and in the photomicrographic form for revealing physiological processes and for studying the growth of plant life.

At present, however, such records are made in a somewhat haphazard manner. There is no deliberate effort to collect representative records of the present age, and as yet no permanent centre where such records could be stored. The 'film library', in fact, is in its infancy. Problems of storage and the whole technique of such a library have received little study. Research has revealed that in the case of negative films taken twenty years ago, the celluloid base is gradually disintegrating. It appears that an acetate base is more stable, and positives on such a base are being made as a stand-by. Evidently this question of the permanence of films of national value is one of great importance, on which further research is needed.

A considerable portion of the report is devoted to the use of films as an educational medium in schools. The film, as a means of instruction, has certain definite advantages over oral methods. It acts as a stimulant, sharpens the critical faculty, and widens the mental horizon, and may be applied to develop dissatisfaction with the inferior and the commonplace. The quality of recollection is more vivid and the impression more lasting than when facts have been presented orally.

It is suggested that films can be applied in three chief ways: (1) in the classroom for teaching, (2) for occasional demonstrations in the school hall on subjects of general interest, and (3) in public cinema theatres, where films making a special appeal to children should be exhibited. Even in such a poor country as Austria, the use of central cinema halls, to which neighbouring schools can send contingents of children, has been developed. Another device, familiar in Italy and Russia, with which experiments have been made in England, is the travelling van.

The great difficulty is that there is at present no machinery for providing contact between university and school staffs and the producer. Many teachers are anxious to obtain educational films, and there are firms willing to make a specialty of producing them, but firms are unwilling to enter upon production without a certainty of a market, and educational authorities are reluctant, even when funds are available, to expend money in this direction without full knowledge that the film will be really suitable for their purpose.

The report contains some data on the cost of production. A feature film, as shown publicly, may cost at least £2000 a week to make and at least £3 a foot in its final form. An educational sound film might cost between 10s and 30s a foot, so that a reel of 1000 ft would cost £500-£1500. The production of such a film demands means of linking the expert skill of the producer and technician with the professional knowledge of the specialist and the teacher.

As regards size of film, it is believed that the 9 mm type is only suitable for the private cinema and for research. It is expedient to aim at the use of the 16 mm standard for classrooms (giving a picture 5 ft x 6 ft or 3 ft x 4 ft), and the full size (35 mm) for halls when films of general interest are shown. In an appendix to the report there is a useful list of projectors, accompanied by particulars of price, pressure, wattage and price of lamps, and other data. Of the types recommended for general educational use, the 16 mm projector costs from £15 to £80 and the 35 mm from £60 to £150. The latter figure would probably have to be multiplied by four if sound production apparatus were included.

The proposed National Film Institute should serve as a positive agency to encourage valuable and good films rather than discourage bad ones. Government recognition appears essential, but the Institute might be either a Government department or institute or an incorporated institute, or a combination of both. Its functions would include acting as a national clearing-house for information and research, assisting in the preparation of film records and serving as a national repository of films of permanent value, the stimulation of public opinion to demand good films, giving advice to teachers and instructors who need films in connexion with their work, acting as a means of liaison with trade, producers, experts, cultural interests, and educators, and encouraging research. Although the present time, when demands for economy are so imperative, is scarcely opportune for advocating the formation of a National Film Institute, it is felt that ultimately the nation would receive a more than adequate return for the expenditure involved.

### Jeremy Bentham, Philosopher and Social Engineer

THE centenary of the death of Jeremy Bentham was commemorated on June 6, at University College, London, when a public lecture was delivered by Mr C. K. Ogden on Bentham's work.

Mr. Ogden dwelt chiefly on those aspects of Bentham's work which, in his opinion, will claim the attention of future generations. His influence on the past and his message for the present were based upon his profound analysis of the symbolic factor in every branch of human activity. Bentham's exposure of word magic was motivated partly by reflections on the fear of ghosts which dominated his childhood, and partly by a dislike of legal fictions generated by Blackstone's lectures at Oxford. It was not until after his sixtieth year, however, that he embarked on the systematic development of his theory of fictions, which anticipated Vaihinger's "*Philosophie des Als Ob*", as well as the modern formalistic account of mathematics. It enabled him to provide a 'technological' account of language, such as modern science demands.

Bentham's most original contribution consisted in the elaboration of a technique of 'archetypation' by means of which the fictions of physics and psychology could be translated into the basic pointing symbols, which are the archetypes of all metaphor, all fictions, and all abbreviations. He himself ex-

plained his social and legal theories, which had so profound an effect upon the history of the nineteenth century, as applications of the principles of experimental science in the field of economics and government. From this same point of view he championed the cause of the inventor and of technical education. His younger brother, Sir Samuel Bentham, the famous marine engineer, and his nephew, George Bentham, one of the founders of systematic botany, were as much his disciples as Ricardo and Jevons in economics or Southwood Smith and Chadwick in matters of public health.

According to Bentham, all language, all symbolic forms, must be interpreted in an *operational* context. Some words point at things as the hands of a clock point at the hours, others, such as 'right', 'faculty', 'motion', 'redness', or 'of', are like single parts or accessories of a clock. They may help us to do the pointing, but any such part taken in isolation is no more than an intriguing piece of metal about which any number of conflicting theories may be held. Put it back in its place, where it helps to perform some operation, and it can be treated functionally. Above all, we can see what substitutes are possible, either for any particular part or for any portion which operates as a unit.

By neglecting the implications of the technological analysis, philosophy has become, almost entirely, the unjustifiable exploitation of the metaphorical, the fictional, and the elliptical. Bentham's method of archetypation, as shown by Prof S M Buchanan's recent study, "Symbolic Distance", does all that the logico-analytical theory of 'incomplete symbols' can do, without resort to logical or mathematical jargon at any point.

Bentham's interest in re-formulation found expression in his powerful advocacy of codification, a word which, like 'international', 'maximise', 'minimise', etc., he himself introduced. But the most significant application of Benthamic principles is in connexion with the problem of a universal (auxiliary) language.

Mr Ogden explained how, by developing certain suggestions put forward by Bentham, he had succeeded in formulating a system whereby 850 English words could be used to take the place of a normal vocabulary of 20,000, for all the purposes of everyday life, general talk, news, trade, and science. To the eye and ear this system, known as 'Basic English', is scarcely distinguishable from standard English, indeed, for some five minutes, Mr Ogden made use only of 'Basic English', a fact of which the audience was unaware until they were informed of it.

Mr Ogden concluded with a plea for a more careful study of Bentham's neglected manuscripts and of the symbolic material printed in his posthumous works. It was Talleyrand who said of Bentham, "Though all the world has stolen from him, he is still rich", and to the inventor and experimenter of the future he may well appear as the founder of a new science, which might be appropriately christened 'Orthology'—the systematic analysis and ordering of symbols at the level of ordinary communication.

## Calendar of Geographical Exploration

### June 19, 1908—Northern Arabia

Alois Musil arrived at Damascus, whence he made surveying expeditions and reached Resafe, 12 miles from the Euphrates, the most northerly point which he visited. Resafe is of great interest because of its ruined churches and palaces and its Greek, Aramaic, and Arabic inscriptions. By several journeys Musil made a plane table survey of the whole region. He made other journeys in face of great difficulties, his work resulted in the preparation of a map of northern Arabia, including the district from 37° to 44° E long and from 36° to 27° N lat. Important additions to the map of Arabia Petraea were made, and much new knowledge of the ethnography, linguistics, and natural history of northern Arabia was gained.

### June 21, 1764—The Falkland Islands

Commodore John Byron, who had taken part twenty-five years before in Anson's circumnavigation, sailed from the Downs to look for islands or lands between the Cape of Good Hope and the Strait of Magellan. His voyage was the first of a series which widened the knowledge of the Pacific. Byron reached the Falkland Islands and took possession of them for King George III, though a French colony had been settled there in the previous year by Bougainville. The islands were discovered by John Davis in 1592 and known as John Davis's South Land. In 1690, John Strong discovered the strait between the two main islands and named it Falkland Sound, the name Falkland being transferred to the whole group by Byron. Byron then discovered the Islands of Disappointment to the north of the Low Archipelago, King George's

Island, and Nukunau or Byron Island in the Gilbert group, ultimately reaching England in 1766.

### June 21, 1882—Alexandra Land

B Leigh Smith, who had previously made three journeys to Spitsbergen, set off with his party to try to reach some vessels off Novaya Zemlya. Leigh Smith had set out in the *Eira*, a steam yacht, in 1880, had sailed along the south side of Franz Josef Land to the west, and had discovered 110 miles of coastline of a new island named Alexandra Land. In 1881, Leigh Smith sailed again for Franz Josef Land, but the vessel was caught in the ice and sank. The party built a hut and wintered on the shore, setting off in boats on the date given above. They were met by the *Willem Barents*, a Dutch vessel which made annual polar explorations for many years.

### June 22, 1878—Voyage of the *Vega*

A E Nordenskiöld left Karlskrona in the *Vega* for his famous voyage round Asia and Europe. The *Vega* sailed through the polar seas off northern Siberia and passed through Bering Strait, "thus after the lapse of 336 years [since Willoughby's voyage] and when most men experienced in navigation had declared the undertaking impossible, was the north-east passage achieved." Nordenskiöld had previously reached the mouth of the Yenisei in 1875 in a walrus-hunting sloop, the *Proeven*, and again in a steamer, the *Ymer*, in 1876. His preparations for the voyage of 1878 were very thorough and included a study of the records of previous travellers in various regions of northern Siberia, chiefly from the point of view of the condition of the ice and the direction of the wind at various dates in different years. The *Lena*, which had accompanied the *Vega*, parted from it at the delta of the Lena River about Aug. 27-28 and steamed to Yakutsk, the first vessel from the northern ocean to reach the heart of Siberia. The *Vega* proceeded eastwards to 67° 4' N and 173° 23' W, when she was shut in by ice on Sept. 29, and the party had to spend the winter there. The diet had been carefully thought out and the health of the party remained good, no case of scurvy occurring, nor was there any case of serious frostbite. Meteorological observations were taken every four hours up to Nov. 1, after that date every hour up to April 1, and then again every four hours. Friendly relations were established with the Chukchi, and during the 10 months' winter much useful ethnographical and linguistic information was collected. The *Vega* sailed on July 18 from its winter home and sighted East Cape (now Cape Dezhnev) on July 20. Data about the Eskimo at Port Clarence were collected, a survey of Bering Strait was made, Bering Island was visited and described, and attempts were made to record the date of extinction of Steller's sea cow (*Rhytina Stelleri*, Cuvier), which was abundant on the island when Bering and Steller were wrecked there. The *Vega* then proceeded to Japan, and afterwards returned to Europe via Ceylon, Aden, and the Suez Canal. The voyage was remarkable for the care with which it was organised, and for the masses of scientific data collected by the distinguished group who accompanied Nordenskiöld, as well as for its pioneer geographical character.

### June 24, 1339—An Early Traveller to China and the East

John Marignolli, a Florentine missionary, left Kaffa, whence he went overland to Kulja and Peking. He stayed four years in China, returning by sea. He describes southern China, gives glowing accounts of the beauties of Ceylon, and mentions Ormuz as a great market town. His descriptions of his overland journey

from the Gulf of Persia to the Mediterranean are full of interesting detail. His narrative is a significant commentary on the ideas of the geography of the world current at that time. From his time onwards no traveller from western Europe passed along the land route to China for two hundred and fifty years.

#### June 24, 1914—The Vilkitski Islands

The Russian explorer, B. A. Vilkitski, started on a voyage in the arctic to survey some previously discovered islands north-west of Cape Chelyushkin. Between 1912 and 1915, Vilkitski accurately charted much of the Siberian arctic coast, made valuable oceanographical observations, discovered Nicholas Land (Northern Land) and two small islands north-west of Cape Chelyushkin, partial surveys of which were carried out in 1914. Bennett Island was also explored, and Jokhov and Vilkitski Islands to the south of it were discovered. The voyage disposed of some erroneous theories about the coast.

### Societies and Academies

#### LONDON

Royal Society, June 9—William A. Bone. The combustion of hydrocarbons (with experiments) (Bakerian lecture). The principal researches and theories concerning the chemical mechanism of hydrocarbon combustion, from the time of John Dalton until now, are reviewed and discussed in three sections, namely (1) nineteenth century discoveries, showing how the successive theories of preferential combustion, whether of hydrogen or carbon, failed, (2) development of the 'hydroxylation' theory (1900–15), together with the relevant experimental evidence from both slow and explosive combustion supporting it, and (3) recent developments—'hydroxylation' v 'peroxidation', in which the two theories are discussed in the light of both old and new experimental evidence.

#### EDINBURGH

Royal Society, May 2—L. Hogben, R. L. Worrall, and I. Zieve. The genetic basis of alcaptonuria. Altogether 151 cases of alcaptonuria recorded in medical literature have been examined. The familiar incidence of the disease satisfies the quantitative requirements of the hypothesis that it is determined by a single autosomal recessive gene substitution. The incidence of consanguineous parentage is in agreement with this conclusion. There is an isolated pedigree in which the disease behaves as a dominant trait.—J. A. Fraser Roberts. The significance of familial incidence in relation to human disease. Studies on familial incidence in relation to human disease are rendered difficult because a random sample of the population can rarely be studied. On the other hand, it is relatively simple to investigate the immediate family history of affected persons. The same difficulty arises in the case of recessive Mendelian inheritance. Owing to the small size of the human family, heterozygotes will frequently have exclusively normal children and such families will not be included in the record. Statistical methods have been worked out for eliminating this difficulty. Precisely similar methods can be applied to the study of human disease in general, whether genetic or not. The only assumption involved is that the affected persons studied are a reasonable sample of such persons. The true familial incidence can be calculated for various groupings of the material and the result discussed in relation to the pathology of the condition and other relevant data.—Hilary B. Moore. The faecal pellets of the

Anomura. A new type of faecal pellet is described, in which there is a system of longitudinal canals in the rod-shaped pellet. These cavities are produced by the solidification of semi-liquid food material round a series of bristle-like processes in the stomach, which are then withdrawn as the pellet proceeds down the gut. The canals in the pellet are arranged in a regular pattern peculiar to the species in question. This type of pellet appears to be peculiar to the Anomura, and appears both in the Galatheidea and the Thallassinidea, but not, apparently, in the Paguridea. In all, the pellets of eighteen species, from twelve different genera, are described. The structure of the pellets suggests that the stomach processes have an absorptive function, and serve greatly to increase the surface area of the gut in these mud and detritus-eating forms.—Alex. R. Horne. Graphical analysis of internal combustion engine indicator diagrams. The indicator diagram which is obtained from the engine records variations of pressure and volume only. The temperature changes, and consequently the fluctuations of internal energy, must be inferred from the values of pressure and volume, for neither of these quantities can be determined from direct experiment. The graphical methods described, when applied to the indicator diagram, make possible the construction of curves of temperature, internal energy, and work done throughout the complete cycle, while the intercepts of the ordinates between the curves of work and internal energy give the interchanges of heat between the working agent and its container. A graphical method of finding the instantaneous value of  $n$  in the law  $pV^n = \text{constant}$  is also given. By its use the rate of heat reception or rejection on the part of the working agent with respect to the rate of change of volume can be simply deduced for any point, or series of points, in the cycle.—W. G. Guthrie. Pressure effects in the secondary spectrum of hydrogen. An experimental investigation on the secondary spectrum of hydrogen as affected by the pressure of the luminous gas. The spectrum obtained with pressures of 40–50 cm is compared with that of the 'vacuum' tube, photographed under similar conditions. Tables of intensities are given for several hundred lines in the visible region.—H. Zwarenstein and I. Schrire. The adrenal gland of *Xenopus laevis*. This gland is essentially similar in distribution and structure to the adrenal of Urodeles. In addition, adrenal tissue occurs in the walls of the renal veins, inferior vena cava, aorta, and renal arteries, a condition similar to that found in some cyclostomes and fishes.—L. M. Milne-Thomson. The zeta function of Jacobi. The elliptic integral of the second kind and the complete elliptic integral of the third kind can be evaluated by means of Jacobi's zeta function. The present paper gives seven-decimal tables of  $Z(u/m)$ ,  $m = K^2$ , with first and second differences at interval 0.01 for  $u$  and 0.1 for  $m$ .—A. Blackwell. The geodesics in Einstein's unified field theory. Using Einstein's 1930 equations for a unified field theory, the geodesics are worked out. In the special case of gravitation alone, these give the motion of perihelion of a planet as  $\frac{1}{2}m^2/h^2$  and the deflexion of a light ray on grazing the sun as  $2m/a$ , whereas, in 1916, Einstein had  $\frac{3m^2}{h^2}$  and  $\frac{4m}{a}$  as the amounts required to account for the observed facts. The estimated shift of the spectrum lines is found to be the same as that given by the 1916 theory.

#### PARIS

Academy of Sciences, May 2—A. Lacroix. Recent falls of meteorites in western Africa.—L. Cayeux. The existence of numerous quartz grains, of atmospheric origin, in the Ordovician in the neighbourhood of

Leningrad The micrographic study of the sands and glauconitic limestones from the neighbourhood of Leningrad shows that, so far back as the Silurian period, the Baltic region was the seat of atmospheric movements strong enough to transport and round off sand grains This confirms the earlier work of Nathorst, who found similar evidence in West Gothland—Charles Nicolle and L Balozet Swine fever is transmissible to man in an invisible form Man is susceptible to this virus but shows no visible symptom Five days after inoculation the human blood injected into pigs gives swine fever—Ch Porcher and Mlle J Brigando The condition of the lime and phosphoric acid in cow's milk A discussion of previous work on the same subject by Piettre, with special reference to the effects of the addition of sodium citrate—Maurice Fréchet The convergence of probabilities *en chaîne*—G Cerf The integration of partial differential equations—Florin Vasilescu The normal derivatives of harmonic functions in the problem of Dirichlet—Pierre Humbert A generalisation of potential—Jacques Devisme Some partial differential equations—G Valiron The directions of Borel of certain integral functions of infinite order—Constantin Woronetz Rolling without slipping of a solid body on a deformable surface—Davin The elastic and plastic state of an indefinite two-dimensional body pierced with a circular hole—J Perès and L Malavard Drawing the lines of current in the Oseen flow round a circle—A Buhl Multipoint movements corresponding to the Jacobi equation written for the case of a single point—Ph Le Corbeiller Maintaining in oscillation the most general passive network—Maurice Curie Phosphorescent sulphides The intervention of collisions of the second kind—D Skobelzyn The degree of homogeneity of the filtered  $\gamma$ -rays of thorium-C'' and the verification of the formula of Klen-Nishina A discussion of the possibility of obtaining a monochromatic radiation by filtration through lead—Mlle Ellen Gleditsch and Ernst Foyn The determination of actinium in uranium minerals Previous work on this has given somewhat discordant results, the difficulties being of a chemical order The author gives full details of his method of separating and purifying the actinium and also protactinium, and gives results for bröggerite and Cornish pitchblende—L Andrieux and D Barbeti The alkaline borides The alkaline borides have not been isolated, but from mixtures with the alkaline earth borides it is shown that their probable formulæ are  $\text{NaB}_6$ ,  $\text{KB}_6$ , and  $\text{LiB}_6$ —Étienne Canals, Marcel Godchot, and Mlle Germaine Cauquil The Raman spectra of some cyclic hydrocarbons The Raman lines for ten hydrocarbons, ranging from cyclopropane to methylcyclooctane are given—Lemarchands and Sirof The determination of barium as chromate Measurements of the solubility of barium chromate in water and in solutions of potassium chloride—P Brauman and S Takvorian A method of preparation of the anhydrous chlorides of the metals of the cerium earths The dry benzoate of the metal is treated with ether and saturated with dry hydrogen chloride The benzoic acid is removed by ether and the anhydrous chloride remains—G Austerweil Some reactions between zeolites and slightly soluble salts—Albert Saint-Maxen The action of magnesium hydroxide on the oxidation of hydroquinone—Andre Kling and Rene Schmutz The action of dilute acids on phenyliminoquinonediazide—R Cornubert and M De Demo Contribution to the study of the dibenzylidene-cyclopentanones—Jean Lacoste The state of the pre-Riffian and Riffian tectonic problem the possibilities of co-ordination—E Chaput Geological observations in Asia Minor The Fusulinidæ formations—Auguste Chevalier The quaternary sea of Timbuctoo—Henry Hubert The

movements of the atmospheric air above Indo-China—G A. Nadson and C A Stern The action at a distance of metals on bacteria and yeasts Lead, copper, and aluminium, not in contact with the cultures, retard the development of bacteria and yeasts, the effect being greater as the atomic weight of the metal is higher—A de Puymaly Observations and remarks on lichens—A Julien and G Morin Cardiac automatism and metabolites in molluscs (*Murex trunculus*)—C Hervieux Jolles' reaction (indican) applied to milk Reply to criticisms by Porcher and Tapernoux—Louis Fage The pelagic phase of coastal benthic Amphipods—Ph Lasseur, P Vernier, A Dupax, and J Marchal Observations on the life of *B caryocyaneus* in media containing lithium salts—A W Sellards and J Laigret The vaccination of man against yellow fever Experiments on an attenuated mouse virus prove that this virus, injected into man, produces an infection without symptoms, followed by immunity It is concluded that the vaccination of man against yellow fever can be realised

## VIENNA

Academy of Sciences, Feb 25—Otmar Eckel Radiation climate of the Kanzel Peak (Carinthia) On this peak, which is 1474 metres above sea-level, the total intensity of the solar radiation reaches 1 gm-cal per sq cm per minute for comparatively low elevations (below 20°) of the sun and, in the middle of the year, amounts to 1.41 at midday The total radiation throughout the year, during which 2165 hours of sunshine are recorded, is among the highest observed in Central Europe In comparison with the thermal radiation of the sun, the ultra-violet radiation of the sun and sky depends very largely on the height of the sun, the total solar ultra-violet radiation on a horizontal surface during a day in July being fifty times as great as on a January day—Karl Mayr Definite integrals and hypergeometric functions New propositions concerning the zero positions of Bessel functions, representations of definite integrals by hypergeometric functions of high order, and relationships between the latter, are deduced—Ernst Spath and Otto Hromatka Dehydration of sapogenin, constitution and synthesis of sapotalin Dehydration of the sapogenin of *Gypsophila* (alb-sapogenin) yields, besides sapotalin, a series of hydrocarbons of high boiling points By a method of synthesis, sapotalin is shown to be 1,2,7-trimethylnaphthalene—Leopold Schmid and Rudolf Falke Action of sodium trityl on inulin in liquid ammonia This reaction gives rise to parabenzhydryltetraphenylmethane in good yield—H Wieseneder Petrographic-geological studies in the Lower Tauern Mountains—Emil Abel and O Smetana The periodate potential In relation to the normal hydrogen potential, the normal potential  $\text{IO}_4^- \rightarrow \text{IO}_3^-$  is  $1.51 \pm 0.01$  volt at 25° The energy relationships for a number of periodate reactions are deduced—Kurt Godel The intuitionistic calculus of expression

March 3—Leopold Schmid and Erwin Kotter Chemical investigation of *Verbascum* flowers The pigment of these flowers is a glucoside of  $\alpha$ -crocin and is accompanied by a dibasic acid,  $\text{C}_{14}\text{H}_{28}(\text{CO}_2\text{H})_2$ , which melts at 124° and has been isolated also from *Thapsia* root—Walter Knapp The action of *o*-phthalyl chloride on the methyl ethers of  $\beta$ -naphthol and of  $\beta$ -thionaphthol In this action the phthalic acid residue enters at the 1-position of the naphthalene system and no formation of phthalide derivatives is observed From the phthaloyl-acids further condensation products, containing a seven-membered ring, are formed—Gerhard Kirsch and Fritz Rieder. Resonance positions of the beryllium nucleus

## Forthcoming Events

## FRIDAY, JUNE 17

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5 —Prof Max Planck The Concept of Causality in Physics (Guthrie Lecture)  
ILLUMINATING ENGINEERING SOCIETY (Annual General Meeting) (at Royal Society of Arts), at 7 15 —Sir Francis Goodenough Presidential Address

## MONDAY, JUNE 20

ROYAL GEOGRAPHICAL SOCIETY (Annual General Meeting), at 3 —Presidential Address, etc

## TUESDAY, JUNE 21

ROYAL SOCIETY OF MEDICINE, at 5 30 —General Meeting of Fellows  
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30 —A T Hopwood The Oldway Expedition (Lecture)  
BRITISH WATERWORKS ASSOCIATION (Annual General Meeting) (at Bournemouth) (continued on June 22 to 25)

## THURSDAY, JUNE 23

ROYAL SOCIETY OF MEDICINE (Urology Section), at 5 30 —Sir John Thomson-Walker Some Changes and Problems in Urology (Address)

## SATURDAY, JUNE 25

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) (Annual Provincial Meeting) (at Alton)  
JOURNÉES MÉDICALES DE BRUXELLES (at Brussels) (continued on June 26 to 28)

## TUESDAY, JUNE 28

NATIONAL PHYSICAL LABORATORY, TEDDINGTON, at 3 —Meeting of the General Board of the Laboratory

## Official Publications Received

## BRITISH

## The Imperial Conference at Ottawa

THE British nation has built great hopes on the Ottawa Conference. The politicians impress us with its importance, though no one seems to have any very clear idea as to what exactly is going to be achieved there. The British Empire is one in speech, in sentiment, and in ideals, but for a number of reasons, some of which are geographical those principles so important to trade and industry which are implied in the term 'Imperial preference' have so far found only partial recognition. The grievous problems which afflict the world to-day cannot be solved by the application of the old remedies; they demand totally new methods of approach and the use of scientific fact and thought. When all is approaching chaos it is for Britain to initiate the recovery, a task which alone may well be too much for the nation, but with the aid of our far-flung Empire the possibilities of success will be infinitely greater.

Nationalism, which at one time was esteemed a virtue, has under existing conditions become very nearly a vice. World trade is gradually ceasing to be, the machinery of international credits and payments has all but come to a standstill. At a time when it is most necessary to increase world trade, and the free interchange of raw materials and manufactured articles is essential, each nation is enacting measures to restrict the purchases of its peoples to home-produced articles, being forced to do so by the pressure of increasing unemployment. Increasing taxation—now beyond the bearable maximum—is merely forcing greater personal economies and aggravating the disease. The sequence of oppressive factors can only be broken by the reopening of world trade by a unit which is big enough to reverse the march of events. One such unit—the British Empire—comprises a quarter of the population of the world, and a like proportion of its area. In the main the Dominions and the Colonies are still producers of raw materials, they still contain vast areas awaiting colonisation and development. The mother land is a manufacturing country importing the necessary raw materials. If we deal only, or mainly, within the Empire, trade may be set going again, British ships will cross the seas, and the railways at home and in the Empire will carry goods from the ports to the manufacturing and consuming centres. It is true that trade will be diverted from the foreigner and to his detriment, but the disadvantage will only be temporary if the wheels of commerce can be set to revolve again in so large a unit as the Empire, for

their momentum will soon begin to draw in other nations who are prepared to trade on a sterling basis

Such is the idea, simple enough in plan but difficult enough in practice, owing to all that has gone before. The question must be approached at Ottawa with full consciousness of its seriousness. The old habit of bargaining must be suppressed and for it substituted the principle of what each can contribute. What is required is not a political or a trade conference, but something much more akin to a scientific meeting at which the ascertained facts are laid on the table and the delegates proceed to make the best possible use out of them. Those who go to Ottawa with executive powers must be instructed to achieve success and not to be content with upholding vested interests, wherein success is defined as the agreeing of measures beneficial to the British Empire and not to any section of it. Sacrifices there will be, but it should be possible to make them of a kind which in the shortest time will prove to be beneficial. The confusing theories of economics, the fetish of gold, must be banned from the discussion. There is opportunity and great need withal for new men, new methods, to lead the Empire back to prosperity. The omens are good. The facts have been collected, industry by industry, well ahead and transmitted by the British Government to the Dominions for study, and it should be possible after broad principles have been willingly and quickly agreed, to get down to details in each industry separately. The Government delegation is a political one, but it includes three special trade advisers, namely, Lord Weir representing the Federation of British Industries, Sir Gilbert Vyle for the Chambers of Commerce and Sir Alan Anderson for the Chambers of Shipping, together with two representatives of agriculture and two labour delegates, making seven industrial advisers in all.

It is open for any industry or trade to send its own representatives to Ottawa, in fact, the Federation of British Industries is advising industries to do so, and it is known that most of the industrial associations are sending expert delegates so that there will be someone at hand to reply without delay to technical questions. It should thus be possible to set up some simple and permanent machinery, both to lay the foundations and erect the superstructure of Empire trade.

The industrial delegates have been organised as a committee by the Federation of British Industries under the chairmanship of Mr W J U Woolcock, for the purpose of co-operating with the three official representatives of business at the Congress. It is realised by industry that it must do something

more than merely wait for the outcome of the political conversations, and there is a widespread movement on foot for each industry to get together with its opposite number in each of the Dominions so as to establish such measure of agreement and effective co-operation as is possible. So far as Canada itself is concerned, wheat and timber are probably the most important items for discussion, on the other hand, British industries are able to supply most of what is now drawn from the United States.

If the whole matter be regarded from a more detached and scientific point of view than is customary for either industrialist or politician, it would seem that there is at least an opportunity for much wider questions to come under review during the discussions. Every thoughtful business man who is engaged in management knows that stabilisation, planning, orderly procedure, prudence, and the adjustment of production to demand, are necessary to keep the economic machine of his own business running steadily and efficiently. Such considerations seem to be forgotten when the unit becomes part of an industry or of the State itself. Here the individualistic creed has asserted itself, and the Darwinian principle of the survival of the fittest prevails. If we believe that there can be too much individualism in the present social organisation, that this creed is principally responsible for the distress in which western civilisation finds itself, then we have to discover how much planning is necessary, by whom it can be done, and what limitations must be imposed. If, however, we take the contrary view and advocate more individualism, smaller units, and abolition of Government interference in any form—in short, a return to the conditions of fifty years ago—then the responsibility of finding work for the nation under the entirely altered world conditions is a heavy one. At Ottawa the first doctrine will be in the ascendant, one of co-operation, of planning so as to ensure the resources of the Empire in men, machinery, and materials being used to the best purpose. The fact that the Conference is under Government auspices, and that definite legislative action to help trade is expected to be its outcome, involves also some measure of control over the planning and its consequences.

Everything depends on the good will of the participants to find a successful solution of the urgent problems, and on their courage to act constructively. Without this, indeed, the hopes of the nation will prove to have been built on a foundation of shifting sands.

## Higher Chemistry for Schools

- (1) *Physical Chemistry* By Arthur Sutcliffe Pp vii + 373 (London John Murray, 1931) 6s net
- (2) *Inorganic and Theoretical Chemistry* By Dr. F Sherwood Taylor Pp xii + 818 + 19 plates (London William Heinemann, Ltd, 1931) 12s 6d
- (3) *Inorganic Chemistry a Textbook for Colleges and Schools* By Dr E J Holmyard Pp xii + 576 + 10 plates (London Edward Arnold and Co, 1931) 6s 6d

(1) **M**R SUTCLIFFE, formerly of the County School at Cambridge, and now headmaster of the City School at Lincoln, has written an attractive book on physical chemistry for sixth form students. The book appears to have been written in response to a real demand for a description, in the simplest possible terms, of the elements of this branch of chemistry, but it is not certain that a separate volume is the best way to meet this demand, in view of the wide extent of the overlap with 'general' inorganic chemistry—an overlap which happily does not occur when the elements of organic chemistry are segregated in a separate volume.

In the present instance, the first six chapters, representing nearly one-third of the text, are given up to a duplication of work that must in any event be included in a course of elementary general chemistry, and very little of it is beyond the scope of a book on inorganic chemistry for sixth form classes. It may be said at once, however, that the compilation of these chapters, and of those which deal with the more familiar branches of physical chemistry, has been very well done, since the author has taken trouble to establish contacts either with first-hand reports on the literature or with the literature itself, as in his citation from Wollaston's paper on "Super-acid and Sub-acid Salts."

The less familiar and more modern sections of physical chemistry are handled in a much less satisfactory way. It is, for example, unfair to a schoolboy to introduce him to a neon atom with eight planetary electrons in a common orbit, and the use of a cubic octet is even more dangerous, since it is in flat contradiction with the tetrahedral configuration of carbon atoms in the diamond, and is here illustrated by a diagram of the electronic structure of sodium chloride, which is definitely misleading. The 'modern form' of the periodic classification of the elements is also incorrect, since it ignores the Rydberg series, assigns only one

element instead of two to the first group, and couples zirconium with cerium instead of with hafnium.

Similar difficulties have arisen from the rapid development of the theory of complete ionisation of strong electrolytes, which has upset so many traditional notions. There is no difficulty in describing the properties of electrolytes in simple terms, which are in strict accord with modern views, but this has not been done, and little good can result from including Arrhenius's theory in a course of school chemistry in the form in which it is here presented. Whilst, therefore, the less ambitious sections can be commended without reserve, the more modern sections are less satisfactory and tend to decrease rather than to increase the value of the book.

(2) Dr F S Taylor's "Inorganic and Theoretical Chemistry" is a well-produced book and is published at a very reasonable price. Attention is at once attracted by the maps inside the covers, which illustrate the distribution of raw materials, and by the nineteen full-page plates. These include pictures of the laboratories of Faraday, of Lavoisier, and of an alchemist (from the picture by Pieter Breughel), followed by ten pictures of crystals, luxuriously displayed on separate pages, three micrographs of steel, and a few miscellaneous illustrations.

Two founts of type are used, since the sections in large type are intended to cover the course which the student would follow in the first year or eighteen months after matriculation, whilst the smaller type is intended to provide for scholarship candidates—or for second year students at the university, who are apparently expected to repeat the work done by scholars during a final year at school. This contingency is by no means impossible, in view of the way in which scholarship candidates are kept at school to the last possible moment, in order to secure a maximum of financial reward, but the claim that the book is suitable for a second year at the university is by no means clearly established, since it has obviously been written for schoolboys rather than for undergraduates.

The book opens with a single historical chapter of seventeen pages, which recalls the names of the great pioneers, and will make a pleasant impression on anyone who is already familiar with the history of chemistry, but since Scheele, Priestley, Black, and Cavendish are disposed of in about a dozen lines each, it is obvious that no serious attempt at historical detail is possible, and it is difficult to say what impression the narrative would make on a

reader who had no historical knowledge with which to supplement the bare outlines of the text

The next seven chapters are devoted to general and theoretical chemistry and are in part of an 'advanced' character. Definitions form a conspicuous feature of these chapters, but are qualified in certain cases by footnotes, which indicate how the older definitions have been modified by later discoveries. The sequence in which information should be given provides at this stage a difficult problem, and one which is, perhaps, incapable of ideal solution. Thus, it must certainly be considered a policy of convenience rather than of logic to insert a section on types of chemical change, including equations, structural formulæ, and even a definition of tautomerism, ten pages in advance of the paragraph in which symbols are assigned to the elements, and, perhaps by a mere oversight, the kilogram-Calorie is used in place of the more familiar calorie before attention is directed on the following page to the significance of the capital C.

In the chapter on "Polar Compounds in Solution" the distinction between the complete ionisation of strong electrolytes and the reversible ionisation of weak electrolytes is mentioned tentatively, but it is not used in practice, since potassium chloride is cited as an example of incomplete ionisation in solution. This chapter is, however, free from the gross contradictions which usually result from incomplete assimilation of the more modern doctrines of electrolytic conduction.

The treatment of the periodic classification is unexpectedly ambitious, since the freshly matriculated student is introduced at once to the whole array of the elements, whilst the small-type student is introduced also to elliptical orbits and to the second (but not to the third and fourth) of the quantum numbers which characterise the planetary electrons. The systematic chapters display a similar lack of compassion, since the immature student is carried remorselessly through the eight columns of Mendeléeff's table, and is expected to learn about the compounds of columbium, the oxides of vanadium, and the chlorides of tantalum before passing on to the discovery of oxygen and the preparation of chlorine. As is well known, this arrangement was tried forty years ago, when Mendeléeff's table still held the field as the best expression of the periodicity of the elements, but even then it was found to be unsuitable for general use, except for works of reference, like Mellor's "Comprehensive Treatise". Its reintroduction at the present day is a retrograde step, in view of the clear-cut classification which has replaced Men-

deléeff's pioneer efforts. It is, for example, no longer necessary to discuss whether hydrogen should be placed in 'Group I, A' or in 'Group VII, B', since the octave or octet on which this classification was founded has not yet begun to operate, and the alternation of A and B groups is now an anachronism for which no obvious justification can be found.

The author's introduction of the electronic theory of valency at an early stage has made it possible to insert a considerable number of electronic structures in the subsequent chapters. By a curious oversight, the  $>\text{SO}$  group is generally represented with a non-polar double bond and the  $>\text{SO}_2$  group with two non-polar double bonds, although a semi-polar

structure is assigned to the  $\text{>NO}$  group, on evidence that it is substantially the same in both cases. Non-polar bonds are also used invariably in formulating metallic salts, even when the ionic character of the linkage is most clearly established, apparently because the author still thinks in terms of Arrhenius, and not of Debye and Huckel.

In conclusion, it should be said that the reviewer's criticisms are to be accepted as a form of congratulation to the author, who has broken new ground in attempting to fertilise the rather arid soil of post-matriculation school chemistry by liberal applications of electronic doctrine, and has achieved a considerable measure of success in doing so.

(3) Dr Holmyard also has introduced a table of electronic structures in the second edition of his "Inorganic Chemistry", but the chapter on the structure of the atom still occupies only twenty pages and is expressed in the simplest possible terms. It therefore adds greatly to the vividness of the story, without making it too difficult to follow.

The other changes made in the new edition are generally very slight, and up to this point the original pagination is retained, although the total bulk of the book has been increased by fourteen pages. A new diagram of a reverberatory furnace has been added, and the old picture of Berzelius has been replaced by a new one, with a balance on the table by his side, but the 'rocker' form of cell for making electrolytic alkali is still retained. A paragraph and a question in reference to hydrogen ion concentration have been added to the chapter on the ionic theory, and a reference to the "Boulevard des Italiens" illuminates the reference to neon lamps.

The elements are discussed systematically in the order of Mendeléeff's table, but this is not a bad

arrangement to use at this relatively elementary stage, since the rare earths and most of the less common transition elements are not cited in the text, although they are mentioned in the titles of the chapters, and most of the others are relegated to the last eighty pages of the book. It is, however, incorrect to limit the term 'transition elements' to the elements of Group VIII, and a similar error, which has not been corrected in the new edition, is found in the Periodic Table itself, where the rare earth elements are placed in Group IV, as if they were quadrivalent, instead of being obstinately trivalent in nearly every case. The classification of hydrogen is also discussed on old-fashioned lines, with the help of a table, which implies that the alkali metals are exclusively monatomic, and with the object of deciding whether hydrogen may be classed "with the halogens" or even "as a halogen", instead of frankly accepting the natural consequences of its unique atomic structure.

The author is, however, to be congratulated on having brought his book up to date with so little change in size or contents, and he would certainly be ill-advised to make any more drastic changes, in view of the success which he has achieved by his original presentation of the subject.

### Physics in the Séance Room

*Les pouvoirs inconnus de l'esprit sur la matière*  
Par Dr Eugène Osty et Marcel Osty Pp 153  
(Paris Félix Alcan, 1932) 25 francs

THE Institut Métapsychique in Paris is an organisation founded for the purpose of investigating psychic phenomena, and in the brochure before us we have a summary of the records of a series of séances held at the Institute. The subject of the inquiry was the young Austrian medium, Mr Rudi Schneider, concerning whom acute controversy has raged for nearly seven years. As in the case of his brother Willi, the most amazing phenomena are reported to occur in his presence, such as the movement of heavy objects without normal contact, the materialisation of human limbs exhibiting all the attributes of life, and many other similar manifestations. The means taken by the investigators to prevent fraud on the part of both mediums have usually been sufficient to exclude their active participation in the more striking phenomena observed, and certain of the investigators have found some difficulty in explaining what they have witnessed in terms of the normal. Indeed, after the recent London sittings one well-known psycho-therapist published a

letter declaring that he had experienced a strong feeling of some mysterious power working from within the cabinet, a power for which he could imagine no "mechanical or pneumatic contrivance."

In the present volume will be found further records which claim to demonstrate the mental control by the medium of some invisible substance at a distance from him, but apparently connected with some obscure form of externalised energy.

Before dealing with these claims, it may be significant to remark that Dr Osty and his collaborator, although they print two pages of anecdotal matter dealing with the biography of the medium, fail to make any reference to certain well-known facts in his history which might throw light on the *modus operandi* of Mr Schneider's more startling manifestations, and which might possibly help in elucidating the nature of that contrivance which appeared to puzzle certain of the London observers. Had these realised the true nature of the problem underlying the Schneider mediumship, they would scarcely have written as they did, for the history of the Schneider brothers is one of the most extraordinary in the annals of psychical research.

So early as 1924, Profs Meyer and Przibram, of Vienna, declared that Mr Rudi Schneider had surreptitiously freed a hand during a sitting, and the statement led to much heated discussion. In 1925, Dr E J Dingwall put forward the theory that confederacy was quite possibly responsible for many of the more striking phenomena produced by the Schneiders, a suggestion followed up in 1926 by Mr Warren J Vinton, who later published a statement that he had felt the confederate crouching behind the medium's chair. Again, in 1927, Mr Malcolm Bird, at that time an official of the American Society for Psychical Research, asserted that he had noticed that the 'materialised' hand was furnished with a normal sleeve, and further, he printed a full account of how in his opinion, the confederate was smuggled in and out of the séance room. In the same year, Dr Walter Prince, of Boston, arranged for a series of sittings with Mr Schneider in Stuttgart, at which the active assistance of a concealed confederate was excluded. Thereupon not one of the more startling phenomena occurred, and both Dr Prince and his collaborator, Mr R Lambert, came to the conclusion that there was no good reason to suppose that any of the manifestations were genuine. In 1929, 1930, and again this year, Mr Rudi Schneider was in London

under the auspices of the National Laboratory of Psychical Research. In the earlier series, startling phenomena were recorded. Human limbs and 'terminals' were observed, 'entities' touched and even brushed past the investigators, and at the end of one of the most extraordinary sittings a match-box, containing some stale matches and unclaimed by anybody, was found near the cabinet! Moreover, during the sittings this year similar wonders have been recorded, if we can judge from the interviews given to the Press by certain of the investigators.

Such in brief are a few of the facts in the life of Mr. Rudi Schneider which are omitted by the authors of this book, facts which have to be considered in any examination of the claims now put forward on his behalf, namely, that in the trance state he is able to externalise a 'force' or form of matter, which can be controlled at a distance by him, and the presence of which can be demonstrated by suitable physical apparatus.

The evidence adduced in support of this claim is derived from an ingenious use of a simple installation whereby infra-red rays are directed upon a certain area and thence to a sensitive cell. After amplification, the current finally passes to an electromagnet, which is so arranged that, if any diminution of the current occurs due to any interruption in the infra-red field, a photograph is taken by flashlight or a bell rung. In later sittings, registration of the phenomena was obtained on photographic paper, this recording time intervals, direction signals, interruptions in the infra-red, and chart of the hyperpnea of the medium in the trance state. Although certain objects were reported as being moved supernormally, this, unfortunately, did not occur when the apparatus was linked up with the cameras, although plates were exposed several times through apparent interruption in the infra-red which induced the flash. In these cases nothing was recorded on the plates which explained how the flash had been set off, the objects on the table under the infra-rays being in the same position. It seemed as if the field were being invaded by some invisible substance, and it was shown how this interruption was under the control of the medium, whose trance personality indicated to the observers when it was to take place, and permitted them to give the signals in order to demonstrate the purposive nature of the phenomena. Moreover, the respiration of the medium, which, in normal state, was of a frequency of about 12 to 14 per minute, increased in the trance state to rates ranging from about

180 to 400. This hyperpnea, so Dr. Osty surmises, is connected in some way with the externalisation of the 'force' which, he is convinced, is responsible for the results, and which in the photographic charts is seen to be connected with respiratory changes.

For reasons which seem scarcely adequate, Dr. Osty omits to give the names of many of his collaborators, and no independent testimony is brought forward to confirm his findings. Since it is clear that the experiments can scarcely be independently verified without the medium, it was all the more incumbent upon the observers to invite additional assistance from trained physicists of established reputation, for not only is it impossible to repeat the experiments in the absence of the subject, but it is equally impossible to criticise them from published accounts and rough drawings. If Dr. Osty's experiments with Mr. Rudi Schneider prove in truth that the human organism in certain states is capable of affecting matter at a distance, then they are obviously of great importance and deserve the most rigorous scientific scrutiny. The present method of psychical researchers is, however, seemingly to avoid that independent examination which is essential to the verification of their claims. It is so common as to be almost universal, and its significance can scarcely fail to be apprehended.

### Methods of Birth-Control

*The Practice of Contraception: an International Symposium and Survey.* Edited by Margaret Sanger and Dr. Hannah M. Stone. From the Proceedings of the Seventh International Birth Control Conference, Zurich, Switzerland, September 1930. Pp. xviii + 316. (Baltimore, Md. The Williams and Wilkins Co., London. Bailière, Tindall and Cox, 1931.) 21s net.

THE urgency of the need for the spread of the knowledge of the means of birth-control is forcing itself more and more on the attention of the public. In these days of sentimental philanthropy, it required courage on the part of Sir Arthur Keith to remind us that war was Nature's pruning knife and the only ultimate means of deciding that the superior race should survive rather than the inferior one. This is only another way of saying that the fundamental cause of war which cannot be dispelled by argument at Geneva, is population pressure. No nation bursting with a rapidly increasing population will allow the question of whether or not it may expand into new territories to be settled for

it by a group of other nations. All those, therefore, who desire peace must strive for the spread of birth-control.

Increasing population does not necessarily mean an increase in the birth-rate. In European countries it means an increase in the *survival-rate*. How great that has been will be seen when we reflect that, exactly a hundred years ago, out of all the children born in London three-quarters died before they were five years' old. The decrease in the death-rate of children has been due chiefly to the efforts of those imbued with humanitarian sentiment. These efforts, intended to add to human happiness, have actually added to human misery, since they have led to the production of large families by the parents least able financially or morally to support them. The only real charity which attacks the evil of poverty at its roots is teaching poor people the methods of birth-control, as Dr Drysdale is reported as saying in the volume which is the subject of this review.

The book consists of a detailed report of the seventh international conference on birth-control, which was held at Zurich in 1930. The author, Mrs Sanger, may be justly termed the heroine of the birth-control movement. Born in New York as a member of a large family of restricted means, she learnt early what the struggle to provide daily bread involved. She took up the profession of district nurse in a poor quarter of New York and her early impressions were deepened, she flamed with just indignation against the make-believe of professional religion and professional medicine. A poor woman among her patients was warned after a difficult birth that another pregnancy would be fatal. When she asked the doctor how to avoid it, he became jocular. The pregnancy duly arrived, and the woman died. On the night of her death, Mrs Sanger tore off her nurse's uniform and decided to devote the rest of her life to the spread of birth-control knowledge. She braved the 'blue' laws of her native country and suffered imprisonment for her propaganda, but she aroused such a wave of popular enthusiasm that she was released, and never again imprisoned. She visited Europe repeatedly, and travelled to India, China, and Japan, and she was largely instrumental in starting birth-control in several countries besides her own. In this volume, however, which she has edited, her personality does not appear; she has produced a marvellous compilation of expert opinions on all methods of preventing unwanted births, from simple vaginal douches to abortion under skilled surgical supervision, as it is practised in Soviet Russia. But

Mrs Sanger herself is opposed to abortion, the chapter dealing with it is only included for the sake of completeness.

It is somewhat disappointing to learn that no single method is to be relied on absolutely, all show a certain percentage of failures, but where the evil is so glaring, a percentage of successes of seventy to eighty per cent—such as is attained by the use of the Dutch cap in Holland—is a great achievement. What is patent is that the ideal method would be the subcutaneous injection of some fluid which would either prevent the dehiscence of the egg or its capacity to unite with the spermatozoon. This method has not yet been discovered, although it appears to hover on the horizon, for we learn from Dr Baker of Oxford that if we were mice and not men it would be possible to inject a hormone which would stop the egg from ripening. But this is not possible in the case of the primates and man, owing to the different sequence of events within the ovary. It is clear, therefore, that in solving this question success will be obtained only when we have attained a far more complete knowledge of the sexual cycle in man than we at present possess, and therefore the greatest aid to the cause of birth-control would be afforded by a continuance of properly directed physiological research. E. W. MACBRIDE.

### Monkey Behaviour and Associations

*The Social Life of Monkeys and Apes*. By S Zuckerman. (International Library of Psychology, Philosophy and Scientific Method). Pp xii + 357 + 24 plates. (London: Kegan Paul and Co., Ltd., 1932). 15s net.

FEW lines of inquiry may be expected to contribute more to forging a link between the biological and social sciences than investigations upon the social behaviour of man's nearest allies. That so little experimental research upon the social behaviour of monkeys has been carried out in the country of Darwin's birth is perhaps surprising and certainly regrettable. In his new book, Dr Zuckerman, who has conducted a series of comparative researches into the characteristics of the reproductive cycle of primates during the past few years, examines the social life of monkeys and apes with the view of elucidating the relation of their habits of association to the peculiarities of their sexual physiology.

The first half of the book is devoted to the thesis that association in the primates—other than man—is primarily conditioned by two circumstances that coexist in primates alone. One is that the cyclical

activity of the sexual organs is not seasonally interrupted by a period of œstrous. The other is that the female receives the male at any stage in the ovarian cycle. From this point of view, Dr Zuckerman classifies mammals in three groups. One includes the majority of orders other than the primates. In these there is a period of œstrous interrupting a succession of periods of heat for a considerable portion of the year. Such mammals form temporary herds for the mating season, and in a few isolated cases associations determined by the nature of their available food supply. A second group, including *inter alia* the field mouse and the reed buck, breed throughout the year, but mate only at such times as the female is on heat. The species belonging to this group do not form associations. Primate associations are not conditioned by the exigencies of food supply. According to Dr Zuckerman, individuals are kept together by the absence of any discontinuity in their sexual relations. The development of this view is supplemented by an extremely lucid presentation of comparative studies upon the œstrous cycle in different orders of mammals. The existing literature on this subject is not easy to follow, and a clear exposition of the field covered by the most recent advances is difficult to find elsewhere.

The second half of the book is devoted principally to a detailed study of the way in which the sexual responses of primates influence the interrelationship of different individuals within the herd. In this section, Dr Zuckerman maintains a conservative attitude to the tendency to emphasise the similarity between the social behaviour of apes and monkeys and the social behaviour of human beings. His point of view may be epitomised in the statement that monkey society rests upon sexuality, whereas human society owes its predominant features to the fact that man is a tool-bearing animal, capitalising the resources of his tool-bearing activities through the machinery of speech. Adopting this attitude, Dr Zuckerman devotes little space to the consideration of psychological studies of the kind which Kohler and his disciples have undertaken. He rightly criticises the *Gestalt* school for constructing a new philosophy on the basis of observation of animals the history of which has not been rigidly controlled from birth.

Dr Zuckerman is one of the very few trained physiologists who have made extensive studies of monkeys in the field as well as in the laboratory. In the latter portion of his book considerable space is devoted to an eminently readable account of his field observations on baboons in South Africa and

his close association with the history of 'Monkey Hill' at the London Zoological Society's gardens. An important part of his task is to reconcile the thesis of the earlier chapters with the phenomenon of 'dominance'. In the baboon society a number of 'overlords' exercise special sexual privileges at the expense of their weaker brethren, the relationship of which to the females is one of 'clandestine promiscuity'. Grooming the fur and homosexuality play an important rôle in consolidating the family nucleus. The actual care of the young is of secondary importance in maintaining the integrity of the group. Monkeys apparently do not distinguish between dead and living individuals as objects for nursing or grooming. The author's theory of the sexual basis of monkey society is thus opposed to the view that altruistic familial responses underlie the social behaviour of the lower primates.

### Short Reviews

*The Archaeology of Somerset* By D. P. Dobson  
(The County Archaeologies) Pp. xv + 272 + 8  
plates (London: Methuen and Co., Ltd., 1931)  
10s. 6d. net

*The Archaeology of Surrey* By D. C. Whimster  
(The County Archaeologies) Pp. xiv + 254 + 12  
plates (London: Methuen and Co., Ltd., 1931)  
10s. 6d. net

(1) Mrs. Dobson's volume on Somerset in the "County Archaeologies" is the most widely general in interest that has yet been published in the series. Not only are all phases of prehistoric culture, excepting the Eolithic, represented in the finds within the county borders, but it also has, in the caves of the Mendips and the lake villages of Glastonbury and Meare, sites of quite exceptional importance for their respective periods. In Roman times the attraction of the lead mines of the Mendips made known the advantages of the country, which would appear to have been appreciated to the full. The wealth of the district in Roman remains is indicated by the number of coins which have been found, here estimated with moderation at 50,000, and by Roman villas, of which that at Keynsham is the largest yet found in Britain. The relative poverty of the area in Saxon remains is in some degree counterbalanced by the historic interest of the one important site, Glastonbury, the only site in Britain on which Christianity claims an unbroken history since its earliest introduction. Somerset's geographical features and position, of which the influence is pointedly indicated by the distribution maps of finds relating to each period within the scope of the book, give the county a special significance for the student of prehistoric culture, to which Mrs. Dobson has done full justice.

(2) Mr. Whimster's "Surrey" is also a volume of exceptional interest. This is due not so much to the number and character of the finds—indeed, Surrey would come off comparatively poorly in

certain periods if it were not for the fact that the County of London, south of the Thames, has been included in this volume—but owing to the treatment of the subject matter. The geographical and geological conditions of the county are such that their relation to culture periods is capable of being treated with exceptional lucidity. Mr. Whimster has not failed to make the fullest use of the opportunity. His diagram, not entirely original, it is true, is a remarkably ingenious piece of graphic statement, and is invaluable as a bird's-eye view of the prehistory of the county. The citation of material from outside the county boundary for purposes of comparison is fuller than it has been in the case of previous volumes, but the nature of the material, especially in the later periods, makes this almost inevitable.

*The Coloured and Colour Breeding*. By T. W. Hogarth. Pp. 54 + 12 plates. (Galashiels. A. Walker and Son, Ltd., 1932.) 6s. 6d.

If we look through genetical literature, we find very little data concerning colour inheritance in dogs. The author of this little book has outlined the history of the coloured bull terrier and gathered together nearly a hundred authentic pedigrees of bull terriers carrying white and coloured blood. 'Coloured' in bull terriers may mean brindle, black, fawn, or red, and these colours with white. The pedigrees indicate the following points: (a) the white bull terrier is not a true white, but a coloured animal inheriting a factor which inhibits the outward expression of the colour except in the nose and eyes; (b) the brindle pattern seems to be of the synthetic type, and is not a true breeding factor, though one or two individuals may exist carrying the definite brindling factor which seems to be established in certain hounds; (c) brindles bred to brindles may produce brindles, blacks, fawns, reds, or whites; (d) the white animals arising from coloured parents may be expected to breed true for white. This latter finding should go far to dispel the prejudices against breeding from such white dogs. Actually it is a means by which the frequent character of deafness in white bull terriers may become dissipated.

Mr. Hogarth has had the collaboration in two chapters of Messrs. Graham and Ritchie of the Royal (Dick) Veterinary College, and Dr. Fraser Darling of the Imperial Bureau of Animal Genetics. If Mr. Hogarth's example were followed for other breeds of dogs, we should hope to accumulate much valuable data for genetical interpretation.

*Les étoiles dans leurs courses*. Par Sir James Jeans. Traduit de l'anglais par A. Sallin. Pp. xi + 205 + 47 planches. (Paris: Hermann et Cie, 1932.) 35 francs.

THIS French translation of a well-known English book is well and accurately done. The translator makes no comment on his work beyond a mention of the fact that he has retained British measures of length, temperature, etc., and added their French equivalents, and he gives at the beginning a key to the determination of one from the other. This

is excellent, but readers to whom the statement of a figure conveys some notion of the order of accuracy implied by it will regret to find, for example, on p. 22, that 53,000 miles is equivalent to 85,287 kilometres. The translator, quite excusably, appears to have failed to recognise the source of the title, which he has translated literally. He has, however, taken the trouble to correct some of the lapses from accuracy in the English book—for example, the date of publication of Copernicus's "De Revolutionibus", at the end of Chapter 1. The printing and paper are excellent, and so are some of the numerous illustrations which form one of the most important features of the book, but others are very badly reproduced. Some are too dark—for example, Plates xvii, xx, xxx—while others, such as Plates xxvii and xxviii, through the opposite fault, are mere travesties of their English prototypes. No acknowledgments of their origin are made. With the exception of the unsatisfactory illustrations, the book can be recommended as worthy of its original.

*Impassioned Clay*. By Llewellyn Powys. Pp. v + 120. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1931.) 6s. net.

THE unknown author of "Ecclesiastes" wrote to deter others from the vanity of excessive indulgence in Oriental pleasures, all was vanity except the fear of God. Omar Khayyám, a man of simple life and desires, expounded the doctrine of ephemeral joy. "Eat, drink and be merry, for to-morrow we die." Each, it will be observed, advocated a course of life inconsistent with his individual practice. To-day we meet Mr. Powys, a self-confessed Epicurean, more consistent than the above, but less pleasant and more dangerous. Happiness is the keynote of Mr. Powys' cry—happiness at all costs, be it sensuous or sensual. He is consistent in his plea for poetry, and perhaps the most dangerous quality in this book is its rhythmic flow. All religions are counterfeits, he tells us, Christianity has ever been opposed to natural happiness. All ethical considerations are man-made, he even goes so far as to mitigate the horror of a drunkard's grave. The book is an open appeal to youth, and it is to be hoped that youth will pass it by. Mr. Powys quotes Hobbes, and a part of the quotation may, as a prayer, end this notice: "Know then that all this is but an empty store of words".

P. L. M.

*Grundriss der allgemeinen Zoologie*. Von Prof. Dr. Alfred Kuhn. Vierte, verbesserte und vermehrte Auflage. Pp. viii + 264. (Leipzig: Georg Thieme, 1931.) 13.20 gold marks.

THE "Grundriss" of Prof. Kuhn, now in its fourth edition, has become a standard textbook of zoology for medical students. It is characteristic of the modern trend in morphology that considerable space is devoted to animal parasites and to heredity. This book can be recommended to English students of zoology as a rapid means of acquiring familiarity with the German language, for the copious illustrations are simple and clearly labelled.

### The Problem of Dental Caries

THE prevalence of dental caries in civilised communities has always excited discussion as to its cause the frequent consumption of sticky sweets has been generally implicated, and their avoidance, together with the eating of fibrous fruits and a proper use of the toothbrush, recommended as a means of prevention. The experimental work of Mrs Mellanby on the relationship between diet and hypoplasia of the teeth led to the conclusion that vitamin D played an important part in tooth development, and further research indicated that there was a relationship between imperfect structure and caries in human beings<sup>1</sup>. The previous emphasis upon the deleterious action of fermenting carbohydrate in the mouth on the enamel of the teeth has therefore tended to shift to an emphasis upon the deleterious action of the food after absorption on the structure of the teeth. In brief, vitamin D is the cure for caries, rather than the toothbrush.

Interest in the problem has recently been aroused afresh by the publication of the report of Surgeon Lieut.-Commander (D) W E A Sampson upon the dental condition of the inhabitants of Tristan da Cunha,<sup>2</sup> as shown by subsequent correspondence in the columns of the *Times*. It may be of value, therefore, to consider what light the dental condition of different peoples throws upon the etiology of caries, to examine how far this evidence agrees with the results obtained in animal and human experiments, and finally to analyse briefly the possible factors involved.

Dental caries does occur in Tristan da Cunha, but the incidence is so low that it would be difficult to find any other community so perfect dentally, and this in spite of the fact that the inhabitants never clean their teeth. Pyorrhœa was only found in two people, who had not been born on the island. The diet consists of fish, potatoes, milk, and eggs, vegetables are occasionally eaten. Until recently, sugar and flour formed no part of the diet, but visiting ships now regularly leave large supplies, which, however, have not, so far, increased the incidence of caries. It may be mentioned also that all the infants are breast-fed.

The dental condition of other communities is also of interest. E Mellanby quotes the investigation of Dr William Hall carried out in Leeds in 1902 upon school children and the Carnegie Report on the inhabitants of the island of Lewis in the Hebrides<sup>3</sup>. In the first case, the teeth of Jewish children were much better than those of Gentile children of the same social standing. Hall considered that differences in dieting were responsible for this, the Jewish children ate large amounts of fish, milk, eggs, and fruit and vegetables, oil was freely used for cooking. In the second case, the children lived under bad environmental conditions and were never taken out until they could walk but they were breast-fed and later lived on fish, especially fish liver, oatmeal, and eggs. Rickets was unknown, and the adults had beautiful teeth.

Another example of the effect of diet on a people's teeth has been described in these columns<sup>4</sup> in an account of the dietary conditions of two African tribes. The incidence of dental defects in Kikuyu children, living on cereals, roots, and fruits, is 30-40 per cent, in Masai children, eating chiefly milk, meat, and blood, 7-8 per cent. The latter have a high intake of protein, fat, and calcium, the former a high intake of carbohydrate and a low one of calcium.

There is also evidence that the teeth of certain races remain in good condition only so long as a particular diet is consumed: thus, Eskimos living on walrus, seal, and fish have good teeth, but dental decay appears so soon as this diet is replaced by the one customary among civilised peoples<sup>5</sup>. Again, in Asia, caries is more prevalent near the centres of civilisation, and appears to accompany the increased consumption of refined carbohydrate<sup>6</sup>.

The general conclusion from these observations is that diet is the important factor in the etiology of caries, and that climate, hereditary influences, and oral hygiene can play only a subsidiary part. Confirmation is obtained from experiments carried out under more strictly controlled conditions. Thus, J D Boyd, C L Drain, and M V Nelson,<sup>7</sup> having observed that caries was arrested in diabetic children who were strictly dieted, tested the effect of a similar diet on normal children and obtained the same result. The diet consisted of milk, cream, butter, eggs, meat, cod-liver oil, vegetables, and fruit. Oral hygiene played no part in the arrest of caries, but unless continuous supervision over the diet was exercised it began to spread again. Bunting and his colleagues<sup>8</sup> similarly found the incidence of caries much less in children given a good diet containing milk, green vegetables, and fruit, with a minimum of white flour and sugar, than in those who used a mouth wash but were not submitted to dietary control. In the former, active caries was present in about 6 per cent and 75-80 per cent had none, in the latter, caries was active in 50 per cent and only 18-20 per cent had none.

E Sprawson has recently published evidence<sup>9</sup> that the provision of a daily allowance of raw milk—that is, milk which has never been heated above body temperature—during the period of development of the teeth, prevents the subsequent onset of caries in these teeth. The children were in institutions, and the diet contained oatmeal porridge and white flour. Many were subnormal on admission, the majority lived so far as possible in the open air.

Mrs Mellanby has recently summarised her work on the prevention and arrest of caries by the administration of vitamin D, and published a further series of cases<sup>10</sup>. The children were in an institution, and the diet was not only rich in vitamin D and calcium, but also free from cereals. Potatoes and other vegetables, milk, fat, meat, and eggs replaced bread, oatmeal, rice, and tapioca, and vitamin D was given in cod-liver oil or as irradiated ergosterol,

and was also present in the egg yolk, butter, and milk. The experiment lasted 6 months and there were 22 children in the group. The average number of teeth per child showing initiation or spread of caries was 0.37, the average number per child showing hardening of caries 4.7, and the average extent of increase of caries was 0.32. (The figures for the previous investigations, in which the diets contained cereals but were supplemented with irradiated ergosterol or cod-liver oil, were respectively 1.0, 3.9, and 1.1, and 1.4, 3.7, and 1.7.) The teeth were hypoplastic and much active caries was present at the beginning of the investigation. The diet, however, prevented almost completely the development of any new points of caries.

There is general agreement that diet is an important factor in the prevention of caries, but controversy has arisen as to its mode of action. Caries is primarily due to the acid formed in the mouth by the fermentation of stagnant carbohydrate attacking the enamel: this implies the presence of an organism (*B. acidophilus*) and stagnant carbohydrate. Caries could then be prevented by ensuring the absence of the organism and carbohydrate by proper dental hygiene, and the presence of well-formed jaws and well-arranged teeth by proper feeding and adequate masticatory exercise during the developmental period. The arrangement of the cusps of the teeth may be such as to favour or prevent the lodgment of food particles, here a hereditary factor may come into play. Immunity to caries must be distinguished from its prevention or arrest: a dirty mouth may be immune because the acid-forming organism cannot establish itself, probably owing to the bactericidal powers of the saliva.

The fact that caries can be arrested, with hardening of the exposed area, indicates that the calcification of the teeth can be influenced after eruption, by substances circulating in the blood stream, just as their calcification can be affected before eruption. These substances are derived ultimately from the food, which must therefore also influence the teeth after digestion and absorption in the intestine, and the evidence suggests that this is a more important factor than its local effect, especially since it has been shown that the structure of the teeth is closely related to the amount of caries present.

The dietary factor is, however, complex, and it appears advisable to stress the necessity of considering the proper balancing of the different constituents, as well as the necessity of examining the relationship of this factor to those of climate and race, in any discussion of the problem. It is always essential in the investigation of the influence of any one factor to keep all other factors as constant as possible, but this may lead to undue importance being attributed to this one factor, and where other factors cannot be completely controlled, as in so many dietary investigations, to neglect of the possible influence of these other factors.

The factors in diet may be briefly summarised: vitamin D, cereals, salts, especially calcium and phosphorus, the total acidity or basicity of the ash

of the diet, and its fibrous or pappy nature. These must be related to the rate of growth, the previous history of both the mother and her infant, including the duration of breast-feeding, the environmental conditions, such as exposure to sunshine and the clothes worn, and finally to the possible influences of race and heredity. A few of these may be considered in more detail. There is no doubt that cereals favour the development of caries, and that vitamin D prevents and arrests it. Some recent investigations indicating that vitamin D is not a main factor are not satisfactory evidence against the controlled experiments of Mrs. Mellanby, but rather show that it is difficult to draw conclusions when many factors are uncontrolled. H. H. Mackay and S. F. Rose compared the teeth of children who had suffered from rickets with those of a control group, of similar age and social class, who had not, and found that hypoplasia of the permanent teeth was almost confined to the rachitic group, but that the amount of caries was only slightly greater in this group than among the controls.<sup>11</sup> It is probable, however, that the rachitic group received a better diet for some time than the non-rachitic, when the rickets was diagnosed, so that afterwards these children were no worse off than the non-rachitic group. Similar results were obtained by A. F. Hess and H. Abramson in an examination of the dental condition of children who had suffered from rickets as compared with that of those who had not.<sup>12</sup> It may also be pointed out that, without strict dietary control, it is not possible to say that a diet which appears the same is actually the same, since it is well known, for example, that the vitamin D content of milk and eggs varies considerably according to the diet and environmental conditions of the cow and fowl.

In considering the balance of the dietary constituents, it is necessary to bear in mind that calcium salts are soluble in acid and that calcium may be withdrawn from the teeth, as from the bones, to neutralise excess of acid in the body, as well as to supply the foetus and infant, if the intake in the food is insufficient.<sup>13</sup>

To sum up, immunity to caries depends on the teeth being properly calcified and the mouth being immune to the growth of the acid-forming bacillus. Prevention of caries in a susceptible mouth depends on oral hygiene and especially on the regulation of the diet, with the view of increasing the resistance of the teeth. Cereals should be avoided, and a plentiful supply of vitamin D (or vitamins A and D) provided, and the diet should contain an abundance of milk, eggs, potatoes, fish, meat, green vegetables, and fruits.

## Recent Advances in the Study of Enzymes

PROF R WILLSTÄTTER, of Munich, and his former pupil, Prof Waldschmidt-Leitz, of Prague, were the chief speakers at a discussion on recent advances in the study of enzymes, held by the Royal Society on June 16. Most of the contributions were primarily descriptions of particular pieces of work, so that the discussion had no formal unity. It was therefore all the more striking that the proceedings should compose so readily into a set of variations on a group of related themes, indicating quite clearly what are the main problems in current enzyme research. Lack of time cut short the beginnings of an interesting general discussion.

There was general support for Prof Willstätter's view that an enzyme consists of an active group of definite chemical constitution, with a colloidal carrier. The question of the nature of the active group is closely bound up with the study of enzyme specificity. Prof Waldschmidt-Leitz described the specificity shown among the peptidases. These enzymes, which have been separated by processes of preferential adsorption and elution from the complex mixtures of proteolytic enzymes found in Nature, are without action on native proteins, but readily hydrolyse polypeptides. They fall into three main groups. The substrate must always have a peptide linkage, but amino-polypeptidases will hydrolyse only those peptides which have a free amino-group, and carboxy-polypeptidases those with a carboxyl group, while di-peptidases will usually attack only dipeptides. The substrate is attached to the enzyme at two points—at the peptide link and at one other group, which varies with the nature of the polypeptidase. The enzyme therefore possesses two combining groups, with chemical affinities for the two groups by which the substrate is held, and so spaced and oriented that they fit in with the structure of the type of polypeptide hydrolysed. This implies rigid chemical structure at the active group of the enzyme. Little is known of the chemical nature of the substrate-holding groups in the enzyme, but similarity between the *pH*-activity curves of peptidases and the effect of hydrogen ion concentration on the combination of sugars and peptides suggests that one of the groups may be chemically related to the sugars.

Many other enzymes appear to hold their substrates at two different points. Dr J H Quastel described work he has done in collaboration with Mr Wheatley on the inhibition of enzymes by a wide range of dyes. The chemical nature of the dye greatly affects the extent of the inhibition, but in general dehydrogenases and urease are sensitive to basic dyes only, while fumarase is also poisoned by acidic dyes. Since the enzyme is protected by the substrate and related compounds from the inhibiting effects of the dyestuffs, it is probable that the toxic action is exerted at the substrate-binding groups. The active groups of dehydrogenases and of urease thus seem to be

acidic in nature, while fumarase attaches its substrate at both an acidic and a basic group. Other examples, based on kinetic evidence, were given by Prof J B S Haldane. Animal lipases were found by Murray, and bacterial dehydrogenases by Woolf, to be inhibited by excess of substrate. The data fit in quantitatively with the hypothesis that in low concentrations the substrate bridges two groups in the enzyme, but in high concentrations inactive complexes tend to be formed, in which each of the enzyme combining groups is linked with a separate molecule of substrate.

Prof Haldane showed, by a series of examples, that there is a marked correlation between specificity in an enzyme and rigidity of structure in its substrates. Specificity is confined to groups in the substrate molecule which are rigid, such as sugar rings. It never appears to extend to groups which are flexible owing to the possibility of rotation, such as saturated chains. Thus absolute specificity is found among the oxidases, but only a wide group specificity among the enzymes hydrolysing peptides or esters. It seems to follow that specificity depends on the fitting together of rigid structures in enzyme and substrate. The rigidity possessed by systems of condensed rings at once suggests this type of structure for the active group of an enzyme. For three enzymes at least, there is good evidence that the activity is associated with iron combined with condensed pyrrol rings to form a hæmatin compound.

This important recent work on the hæmatin nature of some oxidising enzymes was referred to also by Prof Willstätter. It has been shown by Hellstrom and Zeile that highly purified catalase preparations always give the same hæmatin-like spectrum, in an intensity which remains proportional to the catalytic activity through different methods of purification and of inhibition of the enzyme. Similar results have been obtained by Kuhn and his co-workers with the enzyme peroxidase. There was no challenge during the discussion to the conclusion that these two enzymes are hæmatin compounds, but doubts were expressed on the validity of the evidence in the case of a third enzyme, the *atmungsferment* of Warburg. The evidence here is also spectroscopic, but rather indirect. The enzyme, according to Warburg, functions properly only when the cell is intact, when it activates oxygen and so controls cell respiration. Oxygen uptake is depressed by carbon monoxide, and the inhibition is greater in the dark than in the light. The power of light to reverse the inhibition varies with its wave-length, and when this power is plotted against wave-length a hæmatin-like spectrum is obtained, which Warburg regards as the spectrum of the *atmungsferment*. This identification was contested by Prof D Keilin, who described his well-known work on cytochrome. He recognises three factors in cell respiration: dehydrogenases at which the hydrogen of the meta-

bolites is made available, the oxidase, identical with the indophenol oxidase, at which oxygen is mobilised, and the three hæmatin compounds, cytochrome *a*, *b*, and *c*, which act as intermediaries, becoming reduced at the dehydrogenases and re-oxidised at the oxidase. Prof Keilin identifies the *atmungsferment* with the indophenol oxidase, and finds that it differs from typical hæmatin compounds in many of its properties. There is evidence, however, that cytochrome forms a complex with the oxidase, and it is the hæmatin in the cytochrome moiety of this complex which is responsible for the spectrum found by Warburg.

Similar doubts were expressed by Dr Meldrum from rather a different point of view. Dr Meldrum has been working with Dr F J W Roughton on carbonic anhydrase, the enzyme in blood which catalyses the formation of gaseous carbon dioxide from carbonic acid in solution. They have separated it from hæmoglobin, and concentrated it to a very great extent. It is inhibited by cyanides, hydrogen sulphide, and carbon monoxide, and the CO inhibition is reversed by light. These properties in the case of the *atmungsferment* are regarded by Warburg as proofs of its hæmatin nature. But carbonic anhydrase has no trace of a hæmatin spectrum, so that the validity of Warburg's argument is rendered very doubtful.

So far, the nature of the active group of the enzyme has been considered. Prof Willstatter summarised the present knowledge of the colloidal carrier, and described recent work on the relation of the enzyme to the living cell. Enzymes are always obtained as complex colloidal solutions, and the nature of the carrier must be inferred by finding what colloids can be dispensed with. Several American workers claim that enzymes are protein in nature—Sherman with amylase, Sumner with urease, and Northrop with pepsin and trypsin. But amylase has been obtained free from protein, and Sumner's crystalline urease preparation is still active after partial hydrolysis with proteolytic enzymes. Protein-free pepsin was obtained so early as 1861. The carriers seemed to vary with the methods by which the enzyme was extracted from the cell. The properties of an enzyme bound to the cell are often unlike those of the same enzyme in solution. The cell-bound or desmo-enzymes are being actively studied in Prof Willstatter's laboratory, and it has been found, for example, that the desmo-amylase of leucocytes differs from the lyo-amylase in that it is inhibited by glycerol and is active in absence of phosphates.

The relation of the enzyme to the cell was considered from another point of view. Sir Frederick Gowland Hopkins, in his opening remarks, referred to the work of Stephenson and Stuckland on hydrogenlyase. This is an enzyme, found in *B. coli communis* and other bacteria, which catalyses the breakdown of formic acid into carbon dioxide and free hydrogen. The enzyme appears only in cultures which have been grown on broth containing formates. The substrate thus seems to have the power to influence the growing cell so as to induce in it the formation of a new enzyme. Prof A

Harden described a similar phenomenon found with yeast. Normal yeasts ferment only glucose, fructose, and mannose, but the power to ferment galactose may be acquired by yeast grown in a galactose-containing medium. The course of the fermentation appears to be completely normal, the same co-enzyme being required and the same hexose phosphates being formed as in the fermentation of the other sugars. Robison has shown that a mixture of the mono-phosphates of glucose, fructose, and mannose is formed when any one of these sugars is fermented. This suggests that the fermentation takes place through a common intermediate form. Since fructose is fermented the fastest and is the sugar of hexose-diphosphate, this intermediate is probably akin to fructose. The conversion of a sugar into the fermentable form is probably effected by an enzyme or activator specific for the sugar. Such activators may be identical with the hexo-kinase obtained by Meyerhof from yeast, and found by him to enable muscle extracts to use hexoses as a source of lactic acid. The presence of galactose in the growth medium induces the formation in the yeast of a special kinase for galactose.

A distinction between the mode of action of hydrating and oxidising enzymes was brought out in the discussion on the mechanism of enzyme catalysis. Prof Haldane pointed out that hydrating enzymes show symmetrical pH-activity curves, while dehydrogenases give curves rising from the acid side to a plateau in the alkaline region, as required by Woolf's theory. The discussion on the mechanism of enzymic hydrolysis was disappointing. Prof Waldschmidt-Leitz regards union between enzyme and substrate at two points as evidence for the two-affinity theory of Euler, according to which the substrate is bound at one group in the enzyme and caused to react by another. But there seemed to be no indication of this difference of function in the two enzyme combining groups, nor was there any discussion on how the water, which is an essential substrate in a hydrolysis, is brought into the reaction. On the other hand, the mechanism of oxidising enzymes gave rise to a lively exchange of opinion. This discussion is being continued in the correspondence columns of NATURE, so it is only necessary to give the barest summary here.

Prof Willstatter gave an account of the theory he put forward in conjunction with Prof Haber, that the substrates of oxidising enzymes leave the enzyme in the form of free radicals, which initiate chain reactions throughout the medium. Thus

ethyl alcohol would form the radicle  $\text{CH}_3 \overset{\uparrow}{\text{CH}} \text{OH}$ , which interacts with oxygen and a molecule of alcohol to form two molecules of aldehyde and the

radicle  $\text{OH} \overset{\uparrow}{\text{CH}}$ . This takes up a hydrogen atom from a molecule of alcohol, regenerating the first radicle, and so the whole cycle is repeated an indefinite number of times. Prof Haldane criticised this view. It fails to account for the proportionality between enzyme concentration and reaction velocity,

the formation of radicles like OH which react with many different substances contradicts the facts of enzyme specificity, and the theory cannot account for coupled reactions. Dr Richter objected to the idea of free radicles, and supported instead the view of Christiansen that there are chains of molecules with abnormally high energy content. Prof Willstatter replied that such activated molecules would lose their excess energy by collisions before they could enter into chemical reaction. He

admitted the force of some of Prof Haldane's arguments, and said that the formulation involving

↑  
radicles like  $\overset{\uparrow}{\text{O}}\text{H}$  is too simple, and the mechanism must be revised in accordance with the specificity of enzyme action. But whether the chain reaction theory is finally accepted or not, it was made clear by Prof Haldane that it will be of great service in stimulating fundamental experimental work.  
B WOOLF

### Obituary

PROF J W GREGORY, F.R.S.

IN the *Times* of June 14 the brief announcement was made that a wireless message received from Iquitos had been transmitted by Reuters from Lima stating that Prof J W Gregory had been drowned in the Urubamba, near Megantoni Falls in Northern Peru. A subsequent message on the following day confirmed the report and added that Prof Gregory was drowned by the overturning of his canoe in the rapids of Pongo de Mainique in the River Urubamba. The river at this point is only 24 feet wide, the banks consisting of perpendicular rocks of immense height.

Prof Gregory left Liverpool six months ago with a small party of which Miss Mackinnon Wood was one, intending to study the geology of Peru with especial reference to earth movements in recent geological times and the connexion between them and earthquakes and volcanic phenomena. Miss Mackinnon Wood was specially interested in the collection of fossils. As no further particulars of the fate of the rest of the party have been received, it may be presumed that they have escaped disaster. The Peruvian Government afforded every facility to the expedition and is stated to have sent two Peruvian geologists to accompany them.

With the death of Prof Gregory, the most prominent and most widely known British geologist of the present time is removed from the scene. As a writer on geological topics and a lecturer to scientific meetings he had a large public, and his activities as a traveller had made his name well known not in Britain alone but in all parts of the world. He was a ready writer with an easy, fluent style, and was well versed in so many departments of geographical and geological science that his writings cover a vast range of subjects. The mere list of his published volumes is a very impressive one, without taking count of the great series of scientific papers, more than two hundred in number, which came from his pen.

To take a general view of the contributions of a scientific worker so active and so versatile is by no means easy, but we think that Gregory's greatest achievements were in the fields which form a borderland between geology and geography. He will be remembered for his explanation of the rift valleys of Africa, his exposition of the tetrahedral configuration of the earth, his brilliant contribution to the history of the Atlantic and Pacific basins which formed his presidential addresses to the Geological

Society of London, his speculations on the history of valleys and fiords, and the startling hypothesis of the deep-seated and probably volcanic origin of the artesian waters of Central Australia. His mind was constantly occupied with the greater problems of earth structure and history, and his vast erudition gave his opinions a weight which made even those who were most critical of his conclusions treat them with the respect due to profound knowledge and a strikingly original and individual outlook.

Gregory was born in Chelmsford, Essex, in 1864. His father was a wool merchant, and his son assisted him until he was twenty-three years of age. In 1887 he was appointed an assistant in the British Museum, where he served until 1900, when he was appointed professor of geology in the University of Melbourne. He returned from Australia in 1905 to become professor of geology in the University of Glasgow, a post from which he retired on pension in 1929.

At the British Museum, Gregory was engaged principally in the study of fossil Bryozoa, on which he published three volumes of catalogues well known to specialists, but at an early age the *Wanderlust* was strong in him. He visited western North America in 1891 and first attracted attention as a traveller and explorer by his journey in British East Africa in 1892-93. This showed clearly the stuff he was made of, as, in spite of discouragement, difficulty, and danger, he executed a notable piece of work, which characteristically formed the foundation of a brightly written book that thoroughly deserved the great popularity with which it was received. Afterwards he visited, on scientific work intent, almost every quarter of the habitable world. In Spitsbergen, 1896 (with Sir Martin Conway), Central Australia and Queensland (1901-4), Cyrenaica (1908), Southern Angola (1912), Rhodesia and India (several times), North America (repeatedly), and Chinese Tibet (along with his son in 1922) he collected geological information and wrote many geographical and geological papers. In 1919 he was awarded the Victoria Medal of the Royal Geographical Society, in 1922 the Gold Medal of the Scottish Geographical Society and the Galois Medal of the Société Géographique de Paris. These were only a few of the numerous honours which fell to him. He was president of the Geological Society of London (1928-30), and for the second time presided over Section C (Geology) of the British Association at its centenary meeting in London, 1931.

As a professor of geology in Glasgow, Gregory was eminently successful. He had the art of making the subject appear easy and attractive. His classes were the largest in any British university, and he trained a considerable number of students who have afterwards made their mark. Much of this success was due to his remarkable personality. No one could have been more free from assumption or arrogance. His enormous erudition, based on wide reading and a very retentive memory, was free from any kind of ostentation. He was willing to discuss his subject with all comers, however superficial or ignorant, but only those who were experts could appreciate his extraordinary range of vision and realise how much he had seen and learnt. He began his scientific work as a palaeontologist and continued through his whole life to work at that subject, but he wrote also on petrology, translated a book on mineralogy, and was recognised as an authority on mineral deposits, such as copper and gold. He was, for example, one of the first to maintain the theory of the origin of the gold mines of the Rand which now receives the support of the majority of the skilled engineers and geologists who are best acquainted with that field. He published a very useful handbook of economic geology.

My experience of a long friendship with Gregory was that it was very unwise to assume that you knew more of any subject than Gregory did. It was dangerous to differ from him in opinion, as in the quietest possible manner he would produce some devastating facts, well attested but not widely known, that would shatter premature hypotheses.

JOHN S. FLETT

#### DR J. G. GARSON

THE death occurred on June 1, at the age of seventy-seven years, of Dr J. G. Garson of Ewell Court, Surrey. Dr Garson was born in Orkney and was educated at the University of Edinburgh, taking the degree of M.B. in 1875 and of M.D. in 1878. He was admitted a licentiate of the Royal College of Surgeons, Edinburgh, in 1875. He also studied in Vienna, Berlin, and Leipzig. For many years Dr Garson was a prominent figure among anthropologists, especially in connexion with the (Royal) Anthropological Institute, of which he was for long a member of council, and the Anthropological Section of the British Association. He assisted in the revision and re-editing of "Notes and Queries on Anthropology" when a new edition of that manual was issued by the British Association in 1892.

As an anthropologist Dr Garson specialised in craniology, especially in its bearing on race in the prehistory of Western Europe, and he did much to foster in Great Britain a knowledge and appreciation of the work of Broca and other Continental anthropologists. His close association with French anthropologists and his friendship with Bertillon led him to the study of Bertillon's anthropometric methods of criminal identification, and when this method was adopted in police work in England, Dr Garson became adviser to the Home Office on the methods of identification of criminals and the

classification of their records, a position which he continued to hold until the introduction of the fingerprint system. Dr Garson was also lecturer in comparative anatomy at the Charing Cross Hospital and Swiney lecturer of the British Museum. From 1902 until 1904 he acted as assistant general secretary of the British Association for the Advancement of Science, organising the Belfast, Southport, and Cambridge meetings, and was a member of its council until the time of his death.

Dr Garson was the author of a large number of papers contributed to medical and scientific journals, and his services to anthropological studies were widely recognised on the Continent. He received the award of the medal of the French Association for the Advancement of Science in 1914, and was an honorary or corresponding member of the anthropological societies of Berlin, Moscow, Rome, and Paris. During the War he held a commission as captain in the R.A.M.C.

WE regret to learn from the *Chemiker-Zeitung* of the death on March 14 of Prof. M. A. Rakusin, of Moscow, at the age of sixty-three years. Rakusin was principally interested in the chemistry and technology of petroleum. At first a believer in the mineral origin of petroleum, his researches upon its optical activity led him to uphold the theory of its organic origin, and in 1906 he found evidence of the existence in petroleum of cholesterol. From his studies upon the opacity to polarised (though not to ordinary) light of dilute solutions of petroleum in benzene, he developed a theory of the existence of ultra-microscopic carbon particles in petroleum, from the amount of which he attempted to calculate the geological age of the deposit. In his later studies he took up the investigation of adsorption phenomena and biochemical problems. He had undertaken to prepare the section on optical activity for the new edition of the handbook "Das Erdöl".

WE regret to announce the following deaths:

Dr William Briggs, founder of University Correspondence College (1887) and also of University Tutorial College, where practical work in physics, chemistry, and biology was introduced to supplement correspondence courses, on June 19, aged seventy years.

Dr Cuthbert Christy, who travelled extensively in Central Africa and was a member of several British and Belgian commissions on sleeping sickness, on May 29, aged sixty-eight years.

Dr C. Dwight Marsh, formerly physiologist to the United States Bureau of Animal Industry, known for his work on plankton life in fresh-water lakes and the effects of poisonous plants on animals, on April 23, aged seventy-seven years.

Mr Robert E. Montgomery, adviser on animal health to the Colonial Office, on June 11, aged fifty-one years.

Dr Marcus S. Paterson, lately medical superintendent of Colindale Hospital, Hendon, an authority on tuberculosis, on June 1, aged sixty-two years.

## News and Views

### Sunset Glows and the Andean Eruptions

THE possibility that the Andean eruptions of April 10 and the following days might be followed by notable sunset glows, at least in the southern hemisphere, was mentioned in our issue of April 23, p. 604, seeing that the eruptions of Krakatoa and Mont Pelée both gave rise to such effects. A letter dated May 18 received from Mr. T. B. Blathwayt, Box 7532, Johannesburg, suggests that these have already begun. Mr. Blathwayt says "We have had them strongly in evidence the last few weeks both here and in other parts of South Africa, so that they must have begun within two weeks of the outburst in South America. There is a strong, dull red glow extending over the whole sky on most evenings, and I saw it one morning at sunrise." Inquiry at the Meteorological Office (Air Ministry) suggests that this may be the first report of phenomena of this kind to reach England. It may be noted that May is one of the dry months in the neighbourhood of Johannesburg and the weather would not normally be such as to favour the formation of sunset cloud effects; moreover, the low latitude yields short twilight, and only very high clouds would be exposed to the sun's rays for long after sunset or before sunrise. The attention of readers interested in this subject may be directed to an article in the *Meteorological Magazine* of the Meteorological Office for May, in which Dr. C. E. P. Brooks discusses the movements of volcanic dust over the globe following the Krakatoa eruption of Aug. 26–27, 1883. This paper is based largely on the Report of the Krakatoa Committee of the Royal Society, London, 1888.

### Meteorite Craters in Arabia

SINCE the general article in *NATURE* of May 28, p. 781, on meteorite craters was written, a still more remarkable discovery has been made known from the Arabian desert, which was crossed by Mr. H. St. John Philby early this year. On the site of the supposed ancient city of Wabar in the Rub' al Khali, he found two shallow craters, the larger one 100 metres across, together with indications of other craters buried in the sand. Around the craters the ground is thickly strewn with slaggy and cindery material, suggesting a volcano. Near by, a 25-lb. mass of iron together with a few smaller pieces of iron and iron rust were collected. The cindery material proves to be silica-glass and the iron is meteoric nickel-iron. Silica-glass is of rare occurrence in Nature, and this example is the most remarkable yet known, both in the abundance of the material and the variety of its forms. Most of the pieces are complete individuals or 'bombs' with a white cellular interior and a black glossy and pumplily surface, and they range in size down to 'black pearls', which were collected in considerable numbers. Such an association of silica-glass with meteoric iron around craters can be explained only as the result of the fall of an enormous meteorite or a shower of meteorites. Their energy of motion was suddenly transformed into intense heat at a very localised spot, and in the sandy desert a rain of molten silica full of bubbles was

shot out from the craters through vapours of iron and silica. The large quantity of material collected by Mr. Philby has been presented to the British Museum by H. M. the King of the Hijaz and Najd, and a selection of that from Wabar is now exhibited in a lighted wall-case near the entrance to the Mineral Gallery in the Natural History Museum at South Kensington.

### Tenth International Horticultural Congress

THE Tenth International Horticultural Congress was held in Paris on May 30–June 5, on the invitation of the Société Nationale d'Horticulture de France. Great Britain, many European States, Canada, and the United States of America were represented by official delegates. The meetings were held in the rooms of the Société Nationale d'Horticulture in the rue de Grenelle, where the delegates were received by the president of the Society, M. F. David, who was also elected president of the Congress. The papers presented were grouped in sections dealing respectively with fruit-arboriculture, genetics and soil-science, plant-diseases and their treatment, and botanic gardens—their function, organisation, and arrangement. The standing committees appointed at previous congresses met to report progress and to consider further action. The Committee on Nomenclature had for its consideration a list of generic names recommended for use in horticulture to avoid the confusion arising from the use in practice of different names for the same plant. Steps were also taken to arrange for the preparation of lists of species of the more important genera in cultivation. The names adopted would be those valid under the Rules of Botanical Nomenclature as passed by the International Botanical Congress of 1930. Interesting features of the Congress were visits to the Jardin des Plantes, the National School of Horticulture at Versailles, and to a number of horticultural establishments near Paris, including the famous nursery of Vilmorin-Andrieux et Cie, and others at Tours and Orleans. During the Congress, an "Exposition Internationale" arranged by the Horticultural Society was held in the Cours la Reine in Paris.

### Printing Mathematical Expressions

THE London Mathematical Society has recently issued a pamphlet ("Notes on the Preparation of Mathematical Papers" Pp. 19. London: C. F. Hodgson and Son, Ltd. 1s.) of suggestions to authors and others preparing mathematical script for the press. In the preparation of satisfactory mathematical print there are three points which should not be overlooked. (1) The difficulties of the compositor should not be insuperable. Whereas in the past it has often been necessary to cut special pieces of type, frequently with unsightly results, the printer is now generally able to find everything he requires in his fount. (2) The print should be easy of comprehension by the reader for whom it is intended. (3) The printer should also aim at elegance in the display of formulæ.

As an illustration, it is better to print  $\sqrt{a+b}$  than  $\sqrt{a+b}$  in a line of type, since the latter involves irregular spacing between the lines. On the other hand, the second of these expressions is more readily grasped when it can be displayed in a separate line. With the notation now in general use, almost all the symbols required in mathematical work can be so adapted as to be manageable to the compositor. It is pointed out that symbols which are necessarily awkward in appearance are fortunately rare. The present pamphlet is mainly of interest to the professional mathematician, there being no mention of the special symbols employed in such wide offshoots as actuarial mathematics. It includes a collection of the symbols which (in the eyes of a compositor) are better avoided, also a list of the symbols forming part of the stock of an up-to-date mathematical printer.

#### Science and Art in the Textile Industries

In a speech at the annual Conference of the Textile Institute at Leamington Spa on May 19, Dr S G Barker discussed the general relation of science to industry. Dr Barker cited the recent observation in physics that drops of one electrolyte in another when submitted to the action of an electric field exhibit the phenomena of lateral spreading, as an example of the truth that none can say what textile applications will follow even a remote discovery in physical science, or when and how such discoveries will be made. In regard to the concrete benefit of science to the textile industries, Dr Barker asserted that most of the work has been pioneer in character, and that good foundations once well and truly laid are rarely seen again. Unfortunately, the rapid extension of the bounds of physical science in the last decade created an inferiority complex in the minds of many ordinary individuals. The new knowledge appeared so vast and confusing that the minority of experts and investigators responsible for it were placed on a pedestal and their dicta accepted without thinking. Not only did the majority of people fail to realise the significance of the discoveries thus made, but inevitably the discoverer himself was frequently unable to recognise the social or industrial value of his discovery.

In Dr Barker's opinion, the scientific worker must endeavour to provide at the moment more practical results if, when prosperity returns, opportunity is to be afforded for the long-range fundamental researches. Only so can we hope to diminish the disparity between our mechanical skill and our social wisdom, between our power over Nature and the mentality which dictates its use. The challenge thus offered to us affords fresh opportunities for the spirit of adventure and romance which already finds expression so frequently in scientific research, and in regard to the textile industries, Dr Barker stressed the importance of linking science to art and seeking to develop products which possess the supremely important aesthetic appeal. The union of art with science should mean not the degeneration of craftsmanship, but the creation of a progeny which will be economic, utilitarian, artistic, and scientific.

#### National Parks in America

In an article in *The Christian Science Monitor* of May 13, much interesting information is given of the growth of the National Park Service of the United States, and of the projects now under consideration. The inauguration of the first national park took place some sixty years ago, but the National Park Service of the Department of the Interior was established by law of Congress, approved on Aug 25, 1916. Its objects are to promote and regulate the use of the federal areas known as national parks, monuments, and reservations, and "to conserve the scenery and the natural and historic objects and the wild life therein, and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations." Mr Stephen Mather, the 'father' of the national parks, was the first director of the service, but in 1929 he was succeeded by Mr H M Albright. At the present time, the service has the administration of 22 national parks and 36 national monuments, but many others are supervised by the Department of Agriculture and the War Department.

In an interview, Mr Albright referred to the establishment of the Branch of Research and Education of the National Park Service. This has already given much attention to the natural scientific phases of the educational work, which includes the development of the means of informing visitors in the simplest way of the interesting geological and biological features of the parks. Special attention is now being given to the historic aspect. Among the most important projects now being considered are those for national parks in Virginia, Kentucky, Michigan, and Florida. The proposed Shenandoah National Park is in the Blue Ridge Mountains, Virginia, and consists of an irregular strip of virgin forest, 66 miles long and 8-18 miles wide. For the Mammoth Cave National Park the State Legislature of Kentucky has already appropriated 1,500,000 dollars for buying caves and properties in the area. The caves are said to have passages and chambers extending approximately 150 miles on different levels. The Michigan scheme relates to the wilderness area, 45 miles long and 5-9 miles wide, on the shores of Lake Superior and only a little more than twelve miles from the coast of Ontario. The area is called Isle Royale, and it is the home of large herds of moose and caribou. Of a different character is the area of 2000 square miles which it is proposed to preserve in the south and south-west of Florida. This area includes channels, lakes, and swamps bordered by groves and forests filled with tropical vegetation. Another project is to connect the eastern parks by an Eastern National Park-to-Park Highway, giving tourists approximately 2000 miles of road, nearly every mile of which runs through scenic or historic country.

#### Natural Reserves in the Belgian Congo

It is well known that the King of the Belgians has played an active part in the development of scientific institutions in his country, and that he is a keen supporter of research. Among his other interests is the question of the protection of the flora and fauna,

particularly of the tropical colonies of Belgium. So long ago as 1909, after travelling in South Africa and the Congo, he emphasised the necessity of taking measures without delay for saving a part of the fauna and flora, which intense and often unregulated economic development threatens to destroy. In the Congo in particular, this destruction was going on with great rapidity, often without apparent cause. We owe to the intervention of the King of the Belgians the creation, in 1929, of the Parc National Albert, comprising about 357,000 hectares (nearly 1400 square miles). The administration of this reserve is in the hands of a commission of which the King's son, Prince Leopold, is president, and Prof V Van Straelen, director of the Royal Museum of Natural History, Brussels, is vice-president. During last April, King Albert, accompanied by Prof Van Straelen, visited the Kivu Park in the Belgian Congo, having made the journey specially to see for himself the effectiveness of the measures of protection in force. His gesture for the cause of the protection of the fauna and flora is of high importance and should result in intensification of the efforts being made in this direction, not in the Belgian Congo alone but also in other countries.

#### • Bird Invaders in London

THE nesting of the jay in Ladbroke Square in west London, recently reported in *Cage Birds*, is certainly a marked invasion of the metropolitan area by this woodland species, but it has been present in south-east London for years past, and has regularly nested in the grounds of the Horniman Museum at Forest Hill within a few dozen yards of a main road. The curious thing is that it is this shy bird and not the bolder magpie that has colonised London, and that among the typical crows it is the carrion crow and not the building-haunting jackdaw that is the familiar London bird. The colonisation of London by birds of prey is also not in accordance with expectation, the buildings have failed to attract the barn-owl, but the tawny owl is so generally diffused that it has been heard within five minutes' walk of King's Cross Station, while, though the pigeons and ducks in London might have been expected to attract the peregrine falcon, and the sparrows and starlings the sparrow-hawk, the only hawk commonly to be seen is the kestrel, which must subsist there on birds rather than on the mice and insects which are its more usual food.

#### The Advance of Medicine

THE Romanes Lecture entitled "The Advance of Medicine" delivered at Oxford on June 1 by Lord Moynihan, president of the Royal College of Surgeons, who received the honorary degree of DCL on that occasion, has been published by the Clarendon Press (2s 6d net). After an historical introduction in which he briefly reviews the work of Hippocrates, Galen, Vesalius, the Italian anatomists, Harvey, Morgagni, and John Hunter, Lord Moynihan passes on to Lister, whom he describes as the greatest material benefactor of mankind the world has ever known. He attributes Lister's genius to the fact that he was master both of the Hippocratic method of induction

and the Galenic method of deduction, and combined the qualities of a physiologist and clinician. Lord Moynihan deplores the fact that physiology is now losing the close relationship it formerly had with clinical medicine, and urges that physiologists and surgeons should make a common attack upon "the innumerable mysteries of disease". On the other hand, he maintains that though the aid given by physics, chemistry, and physiology is indispensable, these sciences are merely ancillary to medicine, which is a science as well as an art in itself. In view of the fact that laboratory aid, though sometimes decisive or at least helpful, is not seldom negligible, the clinician must maintain his sovereignty. In conclusion, Lord Moynihan exemplifies the humanism of medicine by the work of Harvey, John Hunter, Hillman, who discovered anaesthesia, and Lister. Three appendices to the lecture deal respectively with the ideal training of the surgeon, experiments on animals, and the relation of physics and chemistry to medicine.

#### Modern Oil Production Problems

MR A BEEBY THOMPSON'S recent survey of engineering progress in petroleum production (Institution of Petroleum Technologists, May 10) showed clearly the remarkable changes which modern industrial, chiefly economic, conditions have brought about in the technique of oil mining. Only a few years ago 10,000 ft oil wells and the safe and efficient handling of pressures of 5000 lb were considered impossibilities, unit operation of oilfields, now an accepted principle, was then an unattainable ideal. The modern technique of deep drilling has brought with it a chain of difficult problems confronting oilfield engineers throughout the world. Among these may be mentioned control of flowing wells, freezing of wells as a result of rapid expansion of gas together with formation of ice actually in the well itself; mechanical extraction of oil, that is, pumping and plant to raise oil to the surface from depths of 5000-10,000 ft, involving as it does pump pressures up to several thousand pounds per square inch; crooked holes and their avoidance, air-gas lift efficiency, paraffination of wells where waxy oil is encountered, a difficulty still not satisfactorily solved, the ultimate recovery of oil from at present commercially exhausted pools; disposal of surplus natural gas, particularly in regions far removed from populous areas, and the thorny question of practicability of extending the principle of mining oil measures, as at Pechelbroun. None the less, progress in the last few years has been of such a character that one cannot but anticipate a satisfactory solution to some, if not all, of these problems in the near future, especially when economic conditions in the industry improve.

#### Street Lighting

THE improvement in modern street lighting is largely due to the appointment of public lighting engineers whose whole time is devoted to the work. They pay attention to details which have been previously overlooked or neglected. In *Electrical Industries* for June 15 there is a paper on modern

street lighting by Haydn T. Harrison which brings this out clearly. The outstanding advances took place several years ago, gas and the arc lamp being two of the earliest. The invention of gas mantles largely stopped the use of luminous gas. They also prevented the adoption of the carbon filament electric lamp. The invention of the gas-filled lamp was the last notable step forward. The rapidly increasing use of electricity for street lighting at the present time is due not so much to the efficiency of these lamps as to the fact that light can be distributed from them in any required direction by simple optical means. Hence the most notable feature of modern street lighting is the large number of electric lamps fitted with reflectors or glassware designed specially for distributing the total light most efficiently. The motor vehicle head-light is an excellent example of the adaptability of the gas-filled electric lamps. These lamps only take 20 or 30 watts—the same as a small house lamp. By suitable reflections they produce a beam of light in front of the car which enables the driver to see objects to be avoided on the road 100 yards in advance. No other commercial source of light could be made to do the same thing. In modern street and road lighting, the tendency whenever there is a change of system is to raise the height of the lamps. This improves both the illumination on the road surface and the visibility, except when the weather is very foggy.

#### Electrification of the Great India Peninsula Railway

To a joint meeting of the Institute of Transport and the Institution of Electrical Engineers on April 28, Mr. F. Lydall read a paper giving a general account of the suburban and main line electrification of the G. I. P. Railway. He compared the actual with the anticipated traffic and dealt with the design of the plant and apparatus. The electrified portion of this railway is second only in extent, within the British Empire, to that on the Southern Railway in Great Britain. The length of single track fully equipped is 571 miles, the capacity of the substation plant is 100,000 kilowatts, and there are 272 miles of 100,000-volt transmission line. It joins Bombay, a city of about  $1\frac{1}{2}$  million inhabitants, situated mainly on an island, with Northern and Central India by the North-Eastern main line and with Southern India by the South-Eastern main line. Both these lines have to negotiate the escarpment which runs roughly parallel to the coast about forty miles inland, known as the Ghats. On both sections the ruling gradient is 1 in 37. The reason given why the traffic is less than was anticipated is the world depression of trade, which affects India in general and Bombay in particular. The most prolific source of trouble in electric operation is the propensity of the crows in and near Bombay to build nests with iron wire on the overhead line structures. It is related that one such nest was built of metal spectacle-frames which had been filched by a crow from an open shop-window. During the nesting period, crows fly about with pieces of wire sometimes about a yard long in their beaks, and this naturally sometimes causes short circuits. Flying foxes also have sufficient

spread of 'wing' to hook across the mains on 20,000-volt lines. Methods to overcome these difficulties have been devised.

#### Centre International de Synthèse

THE "Centre International de Synthèse" of Paris is planning—and has already begun work on—three important vocabularies. The first is a vocabulary of the most important terms used by historians, jurists, sociologists, and economists. The second is a historical dictionary of science, considered in its relation to philosophy; it will deal with the mutual influence of philosophy and science throughout the historic periods. The third is a vocabulary which will analyse the more important scientific concepts of to-day, their origin and development, and may throw some light upon the various meanings frequently assigned to the same scientific term. The Centre International de Synthèse was formed in 1925 with the object of co-ordinating researches in various branches of pure science. It is under the direction of M. Henri Berr, and it has among its members and associates many French and foreign savants, as well as some young and active investigators. It has four sections: (1) Synthèse historique, (2) Histoire des Sciences; (3) Sciences de la Nature; and (4) Synthèse générale. These meet weekly, in rotation, and the results of their discussions and labours are published in two periodicals, *Revue de Synthèse* and *Archivon* (*Archivum di Storia della Scienza*). In addition, the Centre holds yearly international meetings (*seminaires*), during which specialists in various branches of science describe recent advances in their respective fields.

#### Literature of Food Investigation

WITH the very belated appearance of the issue for September 1931 of the index to the literature of food investigation (vol. 3, No. 2, September 1931. London: H. M. Stationery Office, 1932. 2s. 6d. net), the third volume of this abstract journal is completed. It is published twice a year from the Low Temperature Research Station at Cambridge, two numbers comprising the volume. This number contains 183 pages and a list of the periodicals read. For the benefit of those who do not know this publication, it may be mentioned that it consists of elaborated titles of papers dealing with the problems of food preservation and marketing, arranged in fifteen different sections, namely, meat, pig-flesh, poultry and game, fish, eggs, dairy produce, fats and oils, fruit and vegetables, grain, crops and seeds, theory of canning, theory of freezing and chilling, bacteriology, mycology, engineering, and finally miscellaneous. It was instituted to enable research institutions in the Empire to keep abreast of progress in preservation and transport of food, but should also be of use to all who are interested in the scientific and practical aspects of this subject.

#### The Seminoles

MISS FRANCES DENSMORE, who has recently returned to Washington from Florida, reports a somewhat unusual attitude of aloofness towards the whites and their civilisation on the part of the Seminole Indians of the Everglades. Apparently they have never become

entirely reconciled since the great Seminole wars at the beginning of the nineteenth century. Miss Densmore visited these Indians on behalf of the Smithsonian Institution, Washington, D C, with the view of the investigation of their music, and although she had been assured that the Seminoles had no songs, she was successful, in the end, in obtaining two hundred phonograph records. In a preliminary statement issued by the Smithsonian Institution, Miss Densmore says that the Seminoles are ruled by 'old men', who remain in seclusion in the Everglades and are rarely seen. A rule is imposed upon the people that they are not to learn, or at least to speak, English. Inter-course with the whites is conducted by signs, except that sometimes they will name prices for the articles they wish to sell. They pride themselves on being a full-blood tribe, and a recent count gave 17 mixed bloods only in a population of 500.

### Breeding Insects

IN a useful note in the *Vasculum* for May (p 61), Prof J W Heslop Harrison gives simple instructions for the breeding of insects for experimental and other purposes. This information about the materials used, the methods of constructing cages for moths and butterflies, and the rather unorthodox methods of wintering pupæ, should help to solve problems which have baffled willing but inexperienced experimenters.

### Announcements

PROF C G SELIGMAN, professor of ethnology in the University of London, has been awarded the Nelson Annandale Gold Medal of the Asiatic Society of Bengal for his "contributions to the study of Anthropology in Asia." This medal, which is awarded triennially, was founded in 1927, and the only previous recipient was Dr Fritz Sarasin, of the Museum für Volkerkunde, Basle.

THE KING, on the recommendation of the Minister of Health, has approved the appointment of Miss Ruth Darwin as a senior commissioner of the Board of Control. Miss Darwin, who is a daughter of the late Sir Horace Darwin, was an honorary commissioner in 1920-30 and has been a commissioner since Jan 1, 1931. She is a member of the committee recently appointed to consider certain issues arising in connexion with the sterilisation of the mentally unfit.

THE twenty-fifth Conference of the Society for Experimental Biology will be held at the laboratory of the Marine Biological Association, Citadel Hill, Plymouth, on July 9-11. Some thirty papers are to be read, and on July 10 a visit will be paid to the laboratories and farms at Dartington Hall, Totnes.

THE fifty-first annual meeting of the Society of Chemical Industry will be held at Nottingham on July 12-15. The presidential address will be delivered on July 13 by Prof G T Morgan, on "Ourselves and Kindred Societies." On the following day, the Messel Medal will be presented to Sir William Pope, who will give an address on "Forty Years of Stereochemistry." The greater part of the meeting

will be devoted to visits to works in the neighbourhood.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—An assistant lecturer in philosophy in the University of Manchester—The Registrar, University of Manchester (June 27). A reader in electrical engineering (telegraphy and telephony) at the Imperial College, City and Guilds College—The Academic Registrar, University of London, South Kensington, S W 7 (July 1). An assistant in the Department of Agricultural Botany of the Edinburgh and East of Scotland College of Agriculture—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (July 1). A full-time master for zoology and botany at the Medway Technical College, Gillingham—Head of the Senior Departments, Medway Technical College, Gillingham, Kent (July 1). An assistant lecturer in pharmaceuticals at the Cardiff Technical College—The Director of Education, City Hall, Cardiff (July 2). An assistant lecturer in geology in the University of Manchester—The Registrar, University, Manchester (July 2). A William Morris Research Fellow in Radiology at Mount Vernon Hospital—The Secretary of the British Empire Cancer Campaign, 12 Grosvenor Crescent, S W 1 (July 2). A part-time lecturer in the Biology Department of the Plymouth and Devonport Technical College—The Secretary for Education, Education Office, Rowe Street, Plymouth (July 5). An Alfred Fripp Memorial Fellow in Child Psychology at Guy's Hospital—The Dean, Guy's Hospital Medical School, S E 1 (July 8). A professor of electrical engineering at the Manchester Municipal College of Technology—The Registrar, College of Technology, Manchester (July 9). A lecturer in physics and mathematics at the Sir John Cass Technical Institute—The Principal, Sir John Cass Technical Institute, Jewry Street, E C 3 (July 9). A head of the Chemistry Department of the Sunderland Technical College—The Principal, Technical College, Sunderland (July 11). A lecturer in zoology at the Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, 88A Gower Street, W C 1 (July 12). Chemists in the Department of the Government Chemist—The Government Chemist, Clement's Inn Passage, W C 2 (July 16). A senior lecturer in economics and politics at the Rhodes University College, Grahamstown—The Secretary, Office of the High Commissioner for the Union of South Africa, 73 Strand, W C 2 (July 30). Evening instructors in advanced building construction, sanitary engineering, and physics, at the Kingston-upon-Thames Technical College—The Principal, Technical College, Kingston-upon-Thames. An assistant master for mathematics at the Halifax Municipal Technical College—The Principal, Municipal Technical College, Halifax. A lecturer in physiology at the Chelsea Polytechnic—The Principal, Chelsea Polytechnic, Manresa Road, S W 3. A whole-time lecturer in biology in the Department of Anatomy of the University of Durham College of Medicine—The Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne.

## Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

## Theory of Induced Polarities in Benzene

RECENTLY in this periodical, Lapworth and Robinson<sup>1</sup> gave a criticism of the theory developed by Erich Huckel<sup>2</sup> of the induced polarities in benzene. This criticism referred mainly to three points, which may be shortly reviewed here (For the details see the note of Lapworth and Robinson.) First, the authors claim that any theory of the influence of groups on the course taken by substitution in benzene must be able to correlate this influence with the influence of the groups on the additive reactions of unsaturated compounds, since these reactions are said to obey the same laws as those that govern aromatic substitution, although in the case of substitution a hydrogen atom\* is expelled, which does not occur in the case of addition. Secondly, they correlate the influence of the different groups on the strength of binding of the H-atoms in benzene with the influence of such groups on the relative strengths of acids and bases. From this correlation they derive certain contradictions. Thirdly, they direct attention to the fact that in certain cases of substitution the loss of the hydrogen atom may happen at some other carbon atom than that which is to be the point of attachment of the new substituent.

With respect to this criticism we would like to make the following comments. In the theory of Huckel any more detailed picture for the mechanism (if the expression 'mechanism' is permissible for a quantum-mechanical process) of substitution reactions was intentionally avoided, since we believe that at present such a picture is not possible without quite arbitrary assumptions. We do not see how the assumption of Lapworth and Robinson that substitution in aromatic compounds is to be considered as an addition followed by the expulsion of the hydrogen atom could be proved either by experimental knowledge or by theoretical considerations. On the contrary, the assumption in Huckel's theory is *not* that the mechanism of substitution is to be considered as an expulsion of the hydrogen atom followed by the addition of the new substituent, but only that for a definite reaction the heat of activation is smaller for a hydrogen atom bound more loosely and greater for a hydrogen atom bound more strongly. It cannot be denied that for all simple substitution reactions which have been investigated *quantitatively* up to the present time this assumption—taking the charge density calculated by Huckel—leads to results which are in agreement with observation, and that not only the differences for the heat of activation of *o*-, *m*-, *p*-substitution can be explained, but also the order of these differences for Cl, Br, I as directing substituents can be predicted by the theory.

In connexion with this, point (3) of the criticism of Lapworth and Robinson may be discussed first. It is obviously quite possible—and according to chemical experience even probable—that in certain cases of substitution reactions, such as the perhalogenation of phenols<sup>3</sup> mentioned by Lapworth

and Robinson, the mechanism of reaction is quite different from that which underlies the substitution reactions discussed in Huckel's paper. But evidently one cannot expect that the theory will be applicable to this quite different type of reaction.

As to points (1) and (2) of Lapworth and Robinson, the criticism fails for similar reasons. The dissociation of an acid or base, point (2), is a process quite different from a substitution reaction, for the reason that in the first case a proton (or an OH<sup>-</sup> group) is freed from the molecule, whereas in the second case a hydrogen atom is freed, and in the first case the rest of the molecule remains as an ion and not as a neutral molecule as it is in the case of substitution reactions. It is clear that not only the influence of the group on the undissociated molecule is of importance for the dissociation, but also on the remaining ion. The latter has nothing to do with the charge density calculated by Huckel. Furthermore, in the case of dissociation, the H<sup>+</sup> or OH<sup>-</sup> is not attached directly to a C-atom in the benzene ring. We cannot see what connexion there is between the dissociation of acids and bases and substitution reactions in benzene. We do not feel it surprising, therefore, that the influence of the different groups on the dissociation is of an entirely different character from the influence on substitution reactions. (As examples may be mentioned  $\alpha$ -,  $\beta$ -,  $\gamma$ -chlorobutyric acid and *o*-, *m*-, *p*-chloro- and nitro-benzoic acids. The chloro- and the nitro-group have here an effect in the *same* sense, namely, strengthening, and at the same time not alternating.) Furthermore, the influence referred to, of groups on dissociation, has been observed in the case of *saturated* compounds also, whereas the directing influence for substitution and addition reactions is characteristic for aromatic and unsaturated compounds.

As to the addition reactions, point (1), nothing is known about the connexion of their mechanism with that of substitution reactions in aromatic compounds. Moreover, there are quite different kinds of addition reactions (for example, addition of alkali, halogens, halogen acid). Therefore also in this case one cannot expect that an explanation which has proved useful for simple substitution reactions will be applicable also to addition reactions—and conversely. It may be possible, however, also in the case of certain addition reactions to explain the influence of substituents on the places of addition by the calculation of the distortion of the charge density produced by the substituent, and it may well be possible that in this case (the addition of halogens, for example) the addition takes place more easily at places of higher electronic density—in contradiction to the case of substitution reactions, where, according to Huckel, the substitution happens more easily at places of lower electronic density, since the mechanism of reaction in the two cases may be quite different. But assumptions like this can be proved only by the quantum-theoretical calculation of the distortion of charge density for compounds for which the addition reactions have been investigated quantitatively, as is the case for substitution reactions discussed in Huckel's paper.

Summarising, we suggest that Lapworth and Robinson are trying to apply the theory of Huckel to cases which are in no simple way connected with the cases for which the theory of Huckel has been developed, and for which alone the theory claims to be applicable. What Lapworth and Robinson attempt, namely, to correlate the influence of groups on entirely different kinds of reactions, could be successful only if a complete theory for the mechanism of reaction for all these cases had been worked out. To give such a complete theory was not the intention

\* For the case of substitution Lapworth and Robinson repeatedly refer to the strength of binding and the expulsion of a *proton*, although as distinct from the case of dissociation of acids we have to deal here not with the proton but with the hydrogen atom. This mistake may perhaps be due to a misprint on page 326 in Huckel's paper, where (last but one line) "H-atom" should be read instead of "H<sup>+</sup>". From the whole discussion, however, it is clear that "H-atom" is to be read

of Huckel's paper. Its purpose was rather merely to show that for the influence of different groups on simple substitution reactions in benzene a simple and intuitive interpretation without detailed assumptions about the mechanism of reaction can be given by means of the quantum theoretical calculation of the distortion of the electronic distribution in the benzene ring produced by the substituent.

### Sulphur Assimilation in Wool Growth

In a series of important papers dealing with 'Bush sickness' of ruminants in New Zealand, T. Rigg<sup>1</sup> and his co-workers at the Cawthron Institute, following on the work of B. C. Aston,<sup>2</sup> established the incidence of this ailment as due to iron deficiency in well-marked localities recognised as 'unhealthy'. So far as the pasturage on healthy and unhealthy areas is concerned, the average seasonal iron content is practically the same. The soil-iron content, however, is in general far greater in the healthy areas, and in the one comparative case where the total iron is actually higher in the unhealthy area, the 5 per cent oxalic acid soluble iron (a rough measure of relative availability) is only one-fourth of that in the healthy area.

From these investigations emerges the startling but apparently unassailable conclusion that ingested soil is an absolutely essential supplement to the pasturage, which in itself, in clean condition, is definitely iron-deficient in all these sheep-rearing areas. The habit of the sheep of ingesting soil has thus provided Rigg with an interesting interpretation of the incidence of the similar 'pinning' sickness of Cheviots, which was unknown when the land was overrun with moles, but made its appearance when the moles were exterminated.

These investigations are also highly significant in relation to the associated nutritional problem of the excessive cystine yield in wool growth compared with the cystine available in normal diet.

To quote Rigg's own words, "an interesting and unexpected result was the great improvement both in growth and in lustre and elasticity of the new wool grown after administration of ferric ammonium citrate. It seems possible, therefore, that 'iron' plays some special rôle in wool growth. Is it possible that the wonderful results in increased wool growth obtained through the provision of a 'lick' of blood meal in the Meteor Downs experiment in Queensland may be due partly to the iron content of the blood meal (approximately 0.2 per cent)? It does not seem probable that the great increase in wool growth (averaging 20 oz. per sheep) was wholly due to the small amount of cystine administered in this way."

Accepting Evans's values<sup>3</sup> for the cystine contents of pastures, it is self-evident that conversion of non-cystine sulphur into cystine must occur, and one means of such conversion may be dependent upon invigorated action of intestinal bacteria, as recently suggested by Dr. Rimington and Mr. Bekker.<sup>4</sup>

Equally evident is the probability that adventitious sulphur as well as adventitious iron may be an essential supplement to the food-stuff. Soil ingestion in the areas investigated by Rigg, which are of volcanic

origin and almost exclusively silicious in character, would not appreciably affect the sulphur intake, yet with the iron supplement not only do the general anæmic symptoms of bush sickness disappear, but, also, the wool, which practically ceases to grow in severe cases, resumes normal growth and lustre, with a well-defined 'break' coincident with the remedial treatment. Pasturage from such soils may well prove to be deficient even in total sulphur (though evidence on this point is lacking). In this event, the stock-water supply, particularly from artesian wells, may assume a special significance.

Evident again is the sweeping conclusion that the view hitherto widely accepted, which regarded the cystine supply as the essential limiting factor in wool production, is now definitely exploded, and that the various attempts to influence wool growth directly by administering cystine-rich fodder were foredoomed to failure.

The situation has thus radically changed since 1927, when I first pointed out the significance of the variable sulphur content of wool in its histological, nutritional, and technical aspects.<sup>5</sup> The extensive scheme of research developed from this, in conjunction with my present and past colleagues and co-workers, Mr. Barritt,<sup>6</sup> Dr. Rimington,<sup>7</sup> and Mr. Bekker,<sup>8</sup> did in fact include an attempt to influence the sulphur content of rabbit wool by addition of varied doses of cystine and of wool hydrolysate, to a standard ration.<sup>9</sup> It was clear from these experiments that the seasonal factor completely masked any possible cystine effect, a difference of as much as 18 per cent in the sulphur content of wool from the same animal between one three months' clip and the next being found equally in the cystine-fed and control animals.

It was, moreover, further observed by Mr. Barritt and Dr. Rimington<sup>7</sup> that the increased sulphur yield was still wholly in the form of cystine.

While the recent developments do not lessen but rather emphasise the importance of the work on sulphur content in relation to wool quality, initiated in these laboratories, they expose the dubiety of attempts to associate with a supposedly specific diet supplement, divergent effects from those obtained with a basal diet control. In view of the above-mentioned and possibly other as yet unrecognised factors, field-work data especially would appear to need very careful consideration before recommendations are made to pastoralists on nutritional methods of improving wool growth and quality.

### Constitution of the Keratin Molecule

OF the two comments which Dr. Rimington<sup>1</sup> has to make on our recent note<sup>2</sup> regarding the constitution of the keratin molecule, one is erroneous and the other misleading. In our original communication, we claim to have shown that the amount of free amino

nitrogen in wool is precisely equivalent to the amount of hydrochloric acid absorbed from solution at pH 1.0 and to the arginine and lysine content of the fibre as determined by Marston.<sup>3</sup> In Rimington's opinion, the significance of these identities is lost because "the guanidine group of arginine does not yield nitrogen with nitrous acid under the usual conditions." Van Slyke and Birchard<sup>4</sup> are quoted in support of the contention, a more recent paper by Plimmer<sup>5</sup> being overlooked. The latter has shown that the guanidine group of arginine is attacked slowly by nitrous acid under the usual conditions, and his data indicate that, in twenty-four hours, reaction with the second amino group is almost complete. The determinations which we made of the free amino nitrogen in wool were all allowed to proceed for twenty-four hours, and there is, in consequence, no necessity to follow Rimington in his speculation "that wool probably contains hydroxylysine or other diamino acid in addition to lysine." The "other diamino acid" is undoubtedly arginine.

In regard to the disagreement between Marston's<sup>3</sup> and Vickery and Block's<sup>6</sup> determinations of the arginine and lysine content of wool, reference must be made to the preceding paper<sup>7</sup> by Vickery, which contains an illuminating comment on the methods employed. He states that "there is, therefore, every reason to believe that the arginine content of human hair may be well over 8.0 per cent", the value he obtained. Similarly, the value of 7.8 per cent for the arginine content of wool is probably low, as also Rimington's own value, obtained, presumably, by the same technique. There is therefore every reason for adopting the higher value of 10.2 per cent, obtained by Marston, as being the true arginine content of wool.

Rimington's second difficulty is that no account was taken in our original communication of the amide nitrogen in wool, which amounts to 1.2 per cent by weight. Even if the amounts of arginine and lysine present in wool are assumed to be the maximum values obtained by Marston, an excess of glutamic and aspartic acids remains unaccounted for after the necessary amounts for combination with arginine and lysine have been deducted from the quantities estimated by Abderhalden<sup>8</sup> in wool. This excess would be available for combination with 0.4 per cent of amide nitrogen. But Abderhalden's determinations of the glutamic and aspartic acid content of wool are known to be low, and since only 7.5 per cent of the wool fibre has so far been accounted for by protein analysis, there can be little doubt that sufficient glutamic and aspartic acids will be found present in wool to account quantitatively for its content of amide nitrogen, as well as for that needed to combine with arginine and lysine. We had proposed to avoid all comment on amide nitrogen until such a relationship had been established, and determinations of the glutamic and aspartic acid content of wool are in progress in this laboratory.

### Adsorption of Weak Electrolytes on Charcoal

WE wish to direct attention to two recent statements about our experiments, which may be misleading if left without comment.

In a paper describing results of wide biological significance, Ockrent<sup>1</sup> has suggested, as an interpretation of our results, that in accordance with his theory of selective adsorption "it is to be expected that in a mixture containing strongly adsorbable undissociated molecules and weakly adsorbable ions (arising either from the presence of salt or by the slight dissociation of acid or base) the more strongly adsorbable component will be preferentially adsorbed." It would seem, however, that if ionic adsorption were normally suppressed by simultaneous molecular adsorption, some degree of adsorption should be observed in solutions of such hydrogen ion concentration that the amount of adsorbate existing in the molecular form is negligible. Ockrent observes a very slight hydrolytic adsorption of sodium salicylate under his conditions (using activated sugar charcoal). On the other hand, with the vacuum-heated charcoals used in our experiments, there was no measurable hydrolytic adsorption of propionate, succinate, or hexoate. Hence, we do not think Ockrent's interpretation correct.

The same criticism applies to the statements of Roychoudry and Mukerjee.<sup>2</sup> In an interesting communication, the latter have established that strong anions and cations are adsorbed by activated charcoals of high purity (cf. Miller<sup>3</sup>). These authors further suggest that these observations are not consistent with our views on adsorption. This surely is due to a misunderstanding. Throughout our work, attention has been confined to a study of the adsorption of weak electrolytes by purified, vacuum-heated charcoals. Such a carbon being degassed, and having very little mineral impurity, should approximate very nearly to a true neutral surface. The results which we obtained indicate clearly that weak organic electrolytes are adsorbed only in the molecular form.<sup>4, 5, 6</sup>

From the above experiments, taken with the earlier work of Miller, we must conclude that the adsorption of weak electrolytes by highly purified charcoals is essentially a different process from the adsorption of strong electrolytes under the same conditions.

### Mechanical Hardness Influenced by Magnetisation

In a paper on "A Correlation between the Mechanical Hardness and the Magnetostrictive Effects of Ferromagnetic Substances",<sup>1</sup> attention was directed to the possibility of annealing or softening a steel rod by 'working it' magnetically.

Recently the work of E. G. Herbert,<sup>2</sup> in which he deals with the hardening of metals by rotating magnetic fields, has been brought to my notice. Herbert says, "The result of the magnetic treatment was an immediate decrease of hardness followed by an increase, stability being attained after 3 hours." The work in 1923 seems to be confirmed by Herbert's work.

A series of four rods were given different degrees

of mechanical hardness by different drawing temperatures. The changes in total length were then measured as the applied magnetising force was increased from zero up to about 950 gauss. The changes in total length for the four rods are shown in Fig. 1. The rods were all of the same length, namely,

FIG. 1

58.5 cm. All four rods increased their lengths for small field strengths, but decreased them for strong. The values of the maximum elongations increase with decrease in scleroscope hardness.

| Rod No. | Scleroscope Hardness | Max. Elongation          |
|---------|----------------------|--------------------------|
| 1       | 70.7                 | $1 \times 10^{-5}$ cm.   |
| 4       | 51.9                 | $3.7 \times 10^{-5}$ cm. |
| 5       | 42.8                 | $5.3 \times 10^{-5}$ cm. |
| 3       | 34.6                 | $8.1 \times 10^{-5}$ cm. |

Each one of the curves in Fig. 1 is the average of 4-6 sets of curves. The steel rod was demagnetised by sending a decreasing  $AC$  through the coil surrounding it. Then the rod was magnetised by a  $DC$ , so that the field was directed upwards in a vertical coil and increased continuously from zero up to a value of about 950 gauss. The deflexions of the extensometer were recorded photographically. This took about 60 seconds for each run. Again the rod was demagnetised, but this time the rod was magnetised by a  $DC$  with the field directed downward instead of upward as in the preceding run. This procedure was repeated 4-6 times, each time a reversal of the  $DC$  field occurred.

Rod No. 5 showed a certain instability, and it was only after repeated reversals of the  $DC$  field, with demagnetisation between runs, that it seemed to settle down. A further study of the preliminary runs on this rod showed that each time the rod was demagnetised, and the field was reversed, the maximum elongation was increased, so that a series of curves was obtained for rod No. 5, not unlike the series of curves shown for the four rods in Fig. 1. If, then, increase of the maximum elongation may be interpreted as an increase in the softening of the rod, and Fig. 1 indicates this, then rod No. 5 showed a softening due to magnetic working. Apparently the work in 1923 caught only the softening which occurs at the time of magnetic treatment, and did not disclose, what Herbert has recently shown, that the magnetic treatment is followed after some time by an increased hardness and stabilisation.

The work of Herbert seems to be a most important contribution to the theory of hardness. It is hoped that the magnetostrictive tests may be carried on much more extensively than has been done, for, in my opinion, the magnetostrictive tests offer one of the

outstanding approaches to the study of the mechanical properties of ferromagnetic materials.

### Neanderthal and Modern Man

THE recent communication by Miss Garrod<sup>1</sup> concerning discoveries of human remains in Palestine raises questions of such wide and general interest, and bears so directly on work in which we have been engaged, that we venture to put forward the following views as to a possible line along which a synthesis may be made of the complicated evidence so far obtained relating to the fossil history of the human family.

Miss Garrod reports the discovery by Mr. MacCown in a Mousterian deposit of the skeleton of a young child, the skull of which had certain features which suggested the Neanderthal race, while "others seemed to be incompatible with it." We are not told what these were, but in the *Times* of May 4, Sir Arthur Keith is reported as saying that while "the front of the skull was Neanderthal, the back of the head was of an entirely new type, more resembling that of modern man", so that the specimen might be regarded as a transitional stage between European Neanderthal and modern man. It is clear that this young form differs considerably from the adult more recently discovered, which, whether it represents a new species or a new genus, is of the neanderthaloid type.

Concerning the difference between the young and adult forms of the skull of *Homo neanderthalensis*, however, we are in the fortunate position of being able to make some definite statements, thanks to the number, now considerable, of adult specimens of the species that are known, and to the Devil's Tower skull discovered by Miss Garrod at Gibraltar, which represents a stage of development of an individual of the Neanderthal race corresponding to a modern human infant of between five and a half and six years of age. Although this Devil's Tower skull is quite clearly Neanderthal, in general form it bears a closer resemblance to modern adult *Homo sapiens* than it does to its own adult (*H. neanderthalensis*) or to the young form of modern *H. sapiens*.

The resemblance between adult *H. sapiens* and young *H. neanderthalensis* suggests that the former may have been descended from the latter by a progressive retention into adult life of characters present in the young stages in the ancestor. This view is but an application of that which was most skillfully developed by Bolk<sup>2</sup> in his demonstration of the changes accompanying the descent of man from other mammals—a view favourably commented upon by Sir Arthur Keith<sup>3</sup> and recently shown to be capable of wide application in the realm of organic evolution,<sup>4</sup> and especially concerned in the production of new generalised types, such as the Insecta or Vertebrata, the generalised character of the original representatives of which may be estimated by the large amount of variation and radiation which the members of these groups have since undergone. Evolution by such means may be referred to as 'fœtalisation', or, more generally, 'pædomorphosis'. The differences between adult *H. neanderthalensis* and adult *H. sapiens* skulls in respect of the dentition, chin, the position of the foramen magnum, and the nature of the frontal eminences, to mention only a few points, are precisely

what would be expected if, in its ontogenetic development, *H sapiens* departed less from its embryonic form than *H neanderthalensis*. In other words, *H sapiens* is simpler or more generalised, and this attribute of his evolution accords well with what has been said above with regard to pedomorphosis. At the same time, of course, *H sapiens* has also evolved along his own progressive lines.

We therefore suggest that the available evidence may be most profitably synthesised by regarding *H neanderthalensis* as the antecedent in consanguinity of *H sapiens*, the descent of the latter having been characterised by pedomorphosis, so that it may be said that *H sapiens* has derived his main characters from young *H neanderthalensis*, the adult characters of *H neanderthalensis* having been discarded and lost by this process. It is interesting to us to note that this view is in substantial agreement with the conclusions with regard to the affinities between *H neanderthalensis* and *H sapiens* at which Prof Hrdlička has arrived from other lines of investigation.<sup>5</sup>

#### Mother-of-Pearl Clouds over Scandinavia in January and February 1932

THE remarkable stratosphere clouds<sup>1</sup> which the late Prof Mohn called mother-of-pearl clouds, again appeared over Scandinavia several times during the months of January and February of this year. Elaborate preparations had been made to obtain photographs and visual observations of these remarkable clouds. All my aurora stations in southern Norway were ready to take photographs as soon as the clouds appeared, and Capt Ween, of the Norwegian Geodetic Survey, in collaboration with me, had made preparations to take photographs with modern photo-theodolites. Further, through the photographic stores of Nerlien in Oslo, I had secured assistance in obtaining photographs and moving pictures of the clouds in natural colours. Through broadcasting and by articles in the Press, I asked people to send me observations of the clouds, and this proved to be a most valuable help, since I received about three hundred most interesting reports from different parts of Scandinavia and Finland.

The clouds were first seen in Oslo on Jan. 14, and during the following week from several parts of northern Norway. On Jan. 27 and 29 they were again seen in Oslo, and about fifty successful photographs for determining the height were secured at my aurora stations in southern Norway. Some photographs were also taken by Capt Ween. During the following two weeks the clouds were observed on several occasions from southern, central, and northern Norway.

On Feb. 19, clouds of exceptional beauty were seen about sunset in southern Norway, about seventy reports, with sketches, and a series of interesting photographs, were received. In Oslo, I observed the clouds for three hours from sunset and from about midnight until the next morning, the clouds being illuminated by the moon. All my aurora stations were in action, and more than a hundred successful photographs, with base lines 27.3-105 km., were taken, first after sunset and then during the night in moonshine.

A series of successful photographs was also taken by Capt Ween, and four very interesting photographs and a moving picture, both in natural colours, were secured by Mr Simonsen and Mr Gibbons, of the firm of Nerlien, Oslo.

The preparation of the large amount of material will undoubtedly reveal much that is new concerning these remarkable clouds. Preliminary measurements of some of the photographs show the same altitudes as before, that is, somewhere between twenty and thirty kilometres.

During the night of Feb. 19-20, I made an interesting observation which may give some idea as to the nature of these clouds. A rather homogeneous cloud happened to be near the moon, and I then observed part of a large corona. From the moon and outwards there was a region of bluish-yellow colour, and then came part of a red ring with an inner radius of between fourteen and fifteen degrees from the moon. The outer radius was not observed. If we assume the outer radius of the red ring to be equal to or greater than 18°, we have<sup>2</sup> for the cloud particles diameters not exceeding 0.0025 mm., the height of the clouds was at that time 21-25 km., according to preliminary measurements.

#### Freshwater and Land Mollusca from British Somaliland

SINCE my letter on climatic changes in British Somaliland was written,<sup>1</sup> Major Connolly has kindly identified for me some freshwater and land mollusca from that Protectorate, collected in the Dumuk tug near Buramo, a few miles from the Abyssinian frontier.

They were extracted from the bank of the dry channel under about fifteen feet of alluvium, and include *Zebrinops revorli* (?) Bgt. and two species of *Subulina*, known from Gallaland, but not before recorded from British Somaliland, namely, *S. erlangeri* Bttgr. and *lacuum* Bttgr.

*Z. revorli* is more or less a desert form. Although these three terrestrial species were found at nearly the same horizon as the freshwater forms and may have fallen or been swept by flood waters into the tug, yet their occurrence at least suggests a pause in deposition when the expanse of alluvium through which the present channel is cut became dry land.

The point is worth investigation, as such a break, if confirmed, may simplify the correlation of variations of climates with other areas.

The remaining species are (1) the widely distributed *Melanoides tuberculata* Mull., and (2) *Planorbis stanleyi* Smith, not previously recorded from British Somaliland, although a living Abyssinian form.

In addition to these five species, *Z. maunorianus* Bgt. was found on the Sorl Haud between Illad and Heman (lat. 48° N and long. E 10°). The distribution of this snail, amongst other details, is given by Connolly in a paper published in 1931.<sup>2</sup>

From the ruins of Gorgab, he identifies *Cerastus somaliensis* Smith, and another species of that genus, unidentifiable by reason of the fragmentary condition of the specimen, also *Sub. erlangeri* Bttgr. and *Limicolaria donaldsoni* Pilsb.

Two small pieces of the shells of freshwater mussels were picked up amongst the ruins of the old town of Elk, forty miles south of Buramo and about thirty from the Abyssinian frontier. These are determined to be (1) a species of *Mutela*, and (2) most probably a

*Umbo* Below Eik is a shallow depression which was once clearly a small lake and is even now swampy during the rainy season. Fragments of glass bangles from the ruins were kindly determined by Mr R. L. Hobson of the British Museum to be of Arab manufacture of the fifteenth century or later. The obvious inference is that desiccation has proceeded rapidly during the last 500 years, although at present the doubt must remain whether the shells were brought from elsewhere for domestic purposes. No mussel shells, however, were found in four other similar ruins examined, a point in favour of their former habitat being Eik.

It may be added that no doubt can exist that a survey dealing with the Pleistocene geology of Somaliland, and including the Northern Frontier Province of Kenya, would provide results of no small scientific interest, especially if archaeological work were undertaken at the same time.

### Specific Heat of Gases at High Temperatures

EVIDENCE has been accumulating in my laboratory that combustion is in general far from being complete at the moment of maximum pressure in closed vessel gaseous explosions even under the best experimental conditions, and that consequently specific heat values for gases at high temperatures determined by the explosion method are much larger than the true values. Much of this evidence has rested upon certain assumptions, such, for example, as that the specific heats of various diatomic gases constituting the diluents in explosive mixtures are practically the same over any given temperature range.<sup>1</sup> But recently Messrs J. R. Brown and A. H. El Din have completed a carefully conducted and extended series of experiments which seem to offer conclusive proof that incomplete combustion at the moment of attainment of maximum pressure in closed vessel explosions is generally so large as to make the explosion method as usually employed unreliable for specific heat determinations.

In these experiments, mixtures of identical composition were exploded in two spherical vessels of different sizes—one 6 inches in diameter and the other 18 inches. Both pressures and heat losses during the explosion period were measured in each vessel. It was found that higher pressures were developed in the larger vessel than in the smaller vessel, and that these higher pressures were not to be explained to any very considerable extent in terms of smaller relative heat losses in the large vessel. The conclusion seems irresistible that combustion is more complete in the larger vessel than in the smaller one, due possibly—at any rate, in part—to the fact that as the time of explosion is greater in the larger vessel, combustion is in a more advanced phase.

Taking the data from one typical experiment in which the explosive mixture was an over-rich carbon monoxide air mixture at atmospheric density, it was found by the usual method of calculation that the apparent specific heat of carbon dioxide over the temperature range of the explosion, after allowing for the measured heat loss, was 15.55 for the small vessel (temperature range 20°–1920° C) and 14.4 for the larger vessel (20°–1990° C). The values for the specific heats of carbon dioxide over these temperature ranges, as given by Partington and Shilling, are 9.75 and 9.81 respectively, and these are in all proba-

bility nearer to the true values than those yielded by the explosions. The inference, then, is that while combustion is more complete in the large vessel than in the smaller one, it is seriously incomplete in both vessels.

Hydrogen explosions in the two vessels yielded apparent specific heats for steam which differ to much the same extent as those for carbon dioxide, but they are nearer to the Partington and Shilling values. An over-rich hydrogen mixture, for example, yielded apparent specific heat values of 10.7 for the smaller vessel (20°–1920° C) and 9.5 for the larger vessel (20°–1985° C). The values given by Partington and Shilling for these temperature ranges are 8.4 and 8.54.

### Relative Excitation of the Three X-ray *L*-Levels with Cathode Rays of Different Velocities

SKINNER, Robinson, and others have studied the relative excitation of the three X-ray levels  $L_{III}$ ,  $L_{II}$ , and  $L_I$ , when for this excitation primary radiation of different wave-length is used. Such experiments may be done by studying the relative intensity of the emission lines which combine with each of the three *L*-levels (Skinner) or by an estimation of the relative intensity of the secondary  $\beta$ -rays which emerge from these levels (Robinson). The following remarkable result was obtained: when the exciting radiation is a little harder than that of the hardest *L*-absorption edge ( $L_I$ ), then the levels  $L_{III}$  and  $L_{II}$  give much more intense lines than the level  $L_I$ . With increasing frequency, however, this relation is totally changed in favour of  $L_I$ . With a frequency about five times as large as that of the *L*-edges,  $L_I$  is excited to a much larger extent than  $L_{II}$  and  $L_{III}$ , so that the generally not very intense lines belonging to  $L_I$  become the most intense lines of the corpuscular  $\beta$ -ray spectrum in the experiments such as done by Robinson. This result points to the large influence of the quantum number  $l$  (which is 1 for  $L_{III}$  and  $L_{II}$  and 0 for  $L_I$ ) on the excitation of the three *L*-sublevels.

It seemed to us worth while to try if a similar effect exists when the excitation is brought about by cathode rays of different velocities. The difficulty with such measurements is that the electrons which penetrate into the anticathode lose their velocity according to the Whiddington law, so that even when the X-ray tube is operated with direct current a whole spectrum of velocities is obtained in the anti-cathode. We have tried to avoid this difficulty in the same manner as has been done for other purposes by Webster. A massive anticathode of beryllium with an extremely thin layer of tungsten was used and the three *L*-levels of tungsten were studied. The thickness of the tungsten was such that not more than 5 per cent of the energy of the cathode rays was absorbed by it. In this case, apart from small corrections, the relative intensities of the X-ray lines coming from the three different *L*-levels give a good idea of the relative cathode ray excitation of these three *L*-levels. The lines  $\beta_2$  ( $L_{III}$ ),  $\beta_1$  ( $L_{II}$ ) and  $\beta_3$  ( $L_I$ ), which lie about in the same region of the spectrum, were used. When the tension varied from 15 to 40 kv, the line  $\beta_1$  gets about 10 per cent more intense relative to  $\beta_2$ , the line  $\beta_3$ , however, gets about 30 per cent more intense relative to  $\beta_2$ . This result is the more interesting because for tungsten the energy difference  $L_{II}-L_{III}$  is about 2.5 times as large as the difference  $L_I-L_{II}$ . It seems, therefore, that here, as in the case of the excita-

tion by primary radiation, the influence of the quantum number  $l$  is of more importance than the energy differences between the three  $L$ -levels

#### Photochemistry of Vitamins A, B, C, D

PROBABLY because our letter in NATURE of May 14, p 720, on this subject was too compressed, some misunderstanding seems to have arisen as to the method which we have described. After reading the remarks of Prof Heilbron and Dr Morton in NATURE of June 11, p 866, we think it may save further difficulties if we reaffirm the purpose of our original communication. We wished to show the possibility and to describe some applications of selective *monochromatic irradiation* as an instrument of research in biological problems.

Before this, filters have been used in order to separate different spectral regions, chiefly because monochromators have not been constructed to give a sufficiently high intensity in the ultra-violet to bring about photochemical changes in a reasonable time. (In 1929 Marshall and Knudson, however, applied monochromatic radiation to ergosterol.) With our instrument, we are able to secure accurately monochromatic light of very high intensity. The use of broad bands of ultra-violet radiation, even though selected with a knowledge of absorption spectra, may often conceal the essential molecular changes which occur in a photochemical reaction. Thus, unless the parent substance is irradiated with strictly monochromatic light, the possibilities are left open (a) that the parent molecule may be destroyed in two or more ways simultaneously, and/or (b) that the daughter molecule may be destroyed by absorption of wavelengths other than that causing its production from the parent. These possibilities cannot be definitely excluded by the use of filters, but only by the use of monochromatic radiation.

The method and its applications (which naturally vary from molecule to molecule) will be described in full in a subsequent publication. Until this complete statement is available, we feel that it will economise in time and space to postpone discussion of the detailed points raised by Heilbron and Morton. We should, however, like to say, in reference to vitamin A, that up to the present we have only recorded the fact that on irradiating carotene we have obtained a band near 3280 Å, at a later date, however, we hope to be able to announce the results of experiments on the nutritive value of samples in which the whole of the carotene has been destroyed. We are also trying to devise physical tests more detailed than those in present use, to apply to our irradiated product and to vitamin A itself.

#### Hexuronic Acid as the Antiscorbutic Factor

At the request of Prof A Szent-Gyorgyi, crystalline hexuronic acid from adrenal glands, kindly supplied by him, was tested by us for antiscorbutic activity. Six guinea-pigs, weighing 260 gm, 275 gm, 300 gm, 280 gm, 295 gm, and 310 gm, were employed in the test. Each animal received 1 mgm of the preparation daily, the first dose being administered when the animals had been six days on the scorbutic diet.

Fifty-five days after the commencement of the experiment the guinea-pigs were chloroformed, owing

to the exhaustion of the supply of hexuronic acid, and were found to be free from macroscopic signs of scurvy at autopsy. The weight of the animals at the time of death was 430 gm, 465 gm, 355 gm, 392 gm, 370 gm, and 442 gm respectively. All the guinea-pigs showed uninterrupted growth during approximately the first forty days, after which time their weights declined slightly. The post-mortem examination did not, however, suggest that this decline was due to scurvy.

The results are, therefore, very similar to those obtained by Svirebely and Szent-Gyorgyi,<sup>1</sup> but, as I pointed out later,<sup>2</sup> although this proves the presence of the antiscorbutic factor in Szent-Gyorgyi's preparation, it does not, in my opinion, afford sufficient evidence of the identity of hexuronic acid with the antiscorbutic factor.

S S ZILVA

Lister Institute of Preventive Medicine,  
London, S W 1, June 11

<sup>1</sup> NATURE, April 16, p 576

<sup>2</sup> NATURE, May 7, p 690

VITAMIN C is the name given to a substance the lack of which causes scurvy. Svirebely and Szent-Gyorgyi have shown (NATURE, April 16 and May 7) that the hexuronic acid which was discovered by one of them, and is present in orange and lemon juice, is capable of preventing scurvy. Furthermore, they have shown that lemon juice has approximately the same antiscorbutic activity as the hexuronic acid present in it. In my opinion, no clearer demonstration could have been given of the identity of hexuronic acid and the vitamin. No circumstantial evidence can have much value against such a direct demonstration. The only possibility of doubt was with regard to the correctness of the experiment. However carefully an experiment is done, there is always the chance of an error, especially in such a subtle question as a deficiency disease. For this reason I asked Dr S S Zilva to repeat our experiments, and supplied the necessary crystalline hexuronic acid. Dr Zilva was kind enough to accept and undertake the work. As he reports above, his experiments were entirely confirmatory, so that no doubt is left whatever regarding the antiscorbutic activity and thus the vitamin nature of the hexuronic acid.

It needs very big assumptions to explain these results in any way other than by supposing that hexuronic acid is in fact the vitamin. An adequate explanation will be given in our detailed report in the *Biochemical Journal* of the observations which led Dr Zilva several years ago to the opinion that the vitamin could not be part of the 'Reducing Factor', and thus could not be identical with hexuronic acid.

#### Central and Peripheral Vision

It is generally stated that the fact, long known to astronomers, that faint stars are seen most distinctly when viewed eccentrically is a phenomenon of dark adaptation, but this is not the case, as exactly the same condition is found with the light-adapted eye, as a simple experiment will show.

If two discs of white paper, each of a diameter of a sixteenth of an inch, be pasted on black cardboard an inch apart and viewed from a distance of twelve to eighteen inches, it will be found that the one that is directly looked at (with one eye) appears much darker than the other. This is observed in broad daylight.

## Research Items

**Ancient Eskimo Art**—Archæological investigations on St Lawrence Island in Northern Alaska, carried out by Mr Moreau B Chambers (Report on Investigations and Field Work of the Smithsonian Institution in 1931, *Pub* 3134), have brought to light evidence from a small village site which has an important bearing on the source and development of Eskimo glyptic art. The village was abandoned many centuries ago when a rich old arctic culture still existed along the coasts of Siberia and Alaska in the vicinity of Bering Strait. The inhabitants lived in small houses, partly underground, with floors of stone-slab and walls of driftwood. Their implements differed little from those of later times, but their art was unique, giving the old Bering Sea culture its distinctive stamp. Bone and walrus ivory were carved by stone tools in many and ingenious forms. Animal figures and human heads are good examples of carving in the round, but the inhabitants excelled in executing graceful curving and flowing lines incised on ivory surfaces. A little more than a thousand years ago the Bering Sea culture underwent a sudden change. Instead of graceful curvilinear designs they used deeper, straighter, and more evenly incised lines. This style, though graceful, was inferior to that which preceded it. It is known as "Punuk" from the island where it was first isolated in 1928. It would appear that the cause of the cultural change was the introduction of iron from Siberia, some hundreds of years before the arrival of the Russians there in the seventeenth century. Chinese records show that iron was being used in Siberia in the third century A.D.

**Buka and Bougainville**—Miss Beatrice Blackwood's preliminary report on her expedition to Buka and Bougainville, Solomon Islands, undertaken in 1929 on the invitation of the Institute of Human Relations, Yale University, has been published (*Oceania*, 2, No 2). The inhabitants of Buka were found to be more affected by contact with white civilisation than had been anticipated, but in Bougainville, especially in the central mountainous portion, they are still very hostile. The mountain people live in scattered settlements of one, two, or three huts at short distances from one another, the coastal and island people in villages varying in size from half a dozen huts to twenty or thirty. Some villages are composed of several hamlets. The huts are long and narrow, with low walls of betel-nut planks and an overhanging roof of sago-palm leaves, in shape somewhat like a flattened Gothic arch. They are arranged in straight lines. Each house is occupied by a family group, and every village has one or more boys' houses. In every village also there is one family of recognised high rank. Rank is hereditary in the female line. The successor to a chief is his eldest sister's eldest son. Marriage is normally exogamous; man and wife as a rule belong to different villages. Child betrothal is the rule. When a suitable girl child is found by a boy's father, he gives her father a present as a sign that she is appropriated. This is the beginning of a long series of reciprocal visits, culminating in a marriage ceremony, the essential part of which is that the couple sit down in close contact and are offered food and drink, which they must pretend to taste, the first meal eaten together being taken afterwards. Marriage is not consummated until after puberty.

**Swarming of the Palolo Worm in March**—In an account of the Polychæta collected during the voyage of Prince Leopold of Belgium to the Dutch East

Indies ("Rés Sci Voyage aux Indes Orientales Néerlandaises", vol 2, Fasc 7, 1931) Prof P Fauvel directs particular attention to a collection of Palolo worms made at Amboina in the Moluccas. This collection includes numerous fragments, up to 30 mm in length, of both sexes, of *Eunice viridis*, all lacking their anterior ends. This epitokous form, which consists of the posterior part of the body containing the reproductive products, detaches itself from the anterior non-sexual part, which remains ensconced in the fissures of the coral reefs. The posterior parts swarm at the surface of the sea, where they shed their sexual products. This swarming of the Palolo and its relation to the phases of the moon has been described by many writers. In the New Hebrides, at Samoa, Tonga, and Viti, swarming occurs in October-November, it is of considerable interest to find that in the bay of Amboina swarming occurred in March. The collection was made on March 28, 1929, the last day of the swarming, towards sunset, and the moon (then sixteen days old) was bright. Besides *Eunice viridis*, numerous portions of *E. dubia* were taken at the same time.

**East-Indian Alcyonarians**—Sir J Arthur Thomson and Miss Laura M I Dean have described a rich collection of alcyonarians from the *Siboga* Expedition to the Dutch East Indies ("The Alcyonacea of the *Siboga* Expedition, with an Addendum to the Gorgonacea" Monographie XIIIId of Uitkomsten op Zoologisch, Botanisch, Oceanographisch en Geologisch Gebied verzameld in Nederlandsch Oost-Indië 1899-1900 aan boord H.M. Siboga Leiden. E. J. Brill, Ltd). The authors have been assisted by Prof W R. Sheriffs (*Dendronephthya*), Miss Dorothy Chalmers (*Siphonogorgia*), and Dr J J Simpson (*Stereonephthya* and some related genera). Amongst the material are two new genera and fifty new species of the Alcyonacea, three new species of the Gorgonacea, and two new species of the Telestacea. Of much interest is the new species *Anthelia simplex*, a primitive form which is represented by a single polyp rising from a thick membranous base, having no calyx and very simple short pinnules, the whole surface of tentacles, body, and base being studded with minute blunt-ended rodlets. For another primitive form, previously described as *Coelogorgia repens* by Thomson and Henderson, the authors establish the new genus *Protodendron*. It is not possible to refer to all the peculiarly interesting new forms and old forms revised which are discussed, described in detail, and beautifully figured in this splendid volume, but the fact that a parasitic copepod has been found, probably for the first time, in an alcyonarian, must be mentioned. This occurred in *Xenia ashworthi*, a dimorphic species in which curious abnormal stunted tentacles were observed. The tip of the abnormal tentacle was bent round to the oral surface where a small swollen pocket was found. These swellings each contained a copepod, usually lying transversely across the pocket, and several carried egg sacs. The pocket cavity, was definitely continuous with the tentacle cavity, and the appearance of the pocket strongly suggested that it is simply an enlargement of the tentacle cavity at the tip into which the copepod has passed from the polyp.

**Vitamins in the Mango**—The mango is a fruit of very great importance to the inhabitants of the tropics, and might find a market in colder climates if conditions of transit, storage, and distribution could be adjusted. Its cultivation spread first from India to

tropical and subtropical America at present, it is gaining favour as a dessert fruit in North America. The vitamin A, C, and D content of certain varieties has recently been investigated by Perry and Zilva (Empire Marketing Board Preliminary Report on the Vitamin Content of the Mango. London H.M. Stationery Office 1s net). The fruit, which was transported at a temperature of 40°-50° F and then kept frozen at -20° C during the experiment, was tested for its growth-promoting power (vitamin A activity) on rats, for its antiscorbutic potency on guinea-pigs, and for its antirachitic effect on rats, comparisons being made in each case with cod-liver oil or lemon juice. The pulp of the three varieties examined contained about the same amount of vitamin A as butter. Two contained as much vitamin C as lemon juice, or even more the pulp or rind of the "Alphonso" variety was found to be a more potent source of vitamin C than lemon juice, containing about twice as much, while the pulp of the "Cawassi Patel" variety contained about as much vitamin as the latter. The "Shendrya" variety, however, contained much less and was about as potent as "Bramley's Seedling" apple. None of the varieties contained any significant amounts of vitamin D. Similar variations in vitamin C content between different varieties of the same fruit have already been noted in the case of apples (NATURE, 127, 75, 1931).

**Browning Root Rot of Cereals**—Farmers in the province of Saskatchewan have been troubled with a root rot of cereals sown after summer fallow. The rot was sufficiently extensive to nullify any of the beneficial effects on yield usually associated with fallowing. Many opinions and theories were prevalent amongst practical men as to the cause of the malady, but two members of the University of Saskatchewan have recently proved that species of *Pythium* are responsible ("Studies on Browning Root Rot of Cereals (II). Some Parasitic Species of *Pythium* and their relation to the Disease", by T. C. Vanterpool and J. H. L. Truscott, *Canadian Journal of Research*, vol. 6, No. 1, pp. 68-93, 1932). The account describes numerous field experiments, which show that the cause of the disease was present in the fallowed soil. From the numerous species of *Pythium* isolated from rotted roots, two, *P. arrhenomanes* v. *Canadensis* and *P. volutum*, were found which upon inoculation reproduced symptoms of the malady. *Pythium volutum* is a new species, and varies greatly in the degree of its parasitism. The present work has shown that the seed treatments previously used against browning root rot are quite unnecessary and, in fact, may aggravate the disease. Hydrogen ion concentration of the soil seems to have no effect upon the distribution of the pathogenic species of *Pythium*, which have actually grown on culture media more acid than any of the prairie soils examined.

**Fungi Pathogenic to Man**—The attention of medical men, mycologists, and others who are interested in fungi pathogenic to man is directed to an account by Mr. J. Ramsbottom, Keeper of Botany in the British Museum (Natural History), published by the Medical Research Council in vol. 8 of "A System of Bacteriology in Relation to Medicine" (London, 1931), and also available separately. After giving an outline of the classification of fungi and of some features of their biology (for example, polymorphism, pleomorphism, strains), the author proceeds to record in systematic sequence, beginning with the Phycomycetes, the fungi which have been described as causing disease in man. Many of these organisms are insufficiently described and their systematic position doubtful. The majority of the pathogenic forms are classed as Fungi Imper-

fecti, as the spore forms known do not include the sexual or perfect stage. The account concludes with a more detailed consideration of the ringworm fungi.

**Tectonic Analysis of the Mourne Mountains**—Dr. H. P. T. Rohleder has carried out a tectonic investigation of the Tertiary granite mass of the Mourne Mountains, applying the principles developed by Prof. Cloos of Bonn (*Proc. Roy. Irish Acad.*, 40, B, 12, 160-174, 1932). The pre-existing trend-lines of the Silurian country rock showed the way to the pre-granitic basalt dykes. These have been cut off abruptly by the granite which domed up the overlying strata to form a 'discordant laccolith'. During the phase of cooling, there came up quartz-porphry dykes and aplites, followed by basic veins representing post-plutonic pneumatolytic and hydrothermal activity. In the post-granitic phase, a second series of basalt dykes intersected the granite and the neighbouring Silurian rocks. Vertical joints can be traced in all the members of this complex. There are four dominant directions: a system of principal joints at 16° and 94° (measured clockwise from true north), and a system of diagonal joints at 50° and 149°. The quartz-porphry and aplite dykes follow mainly the 16° joints and to a less extent the diagonal directions. The 94° joints are avoided until all the other potential openings have been filled. Only the younger basalt dykes show an obvious majority in the 94° direction. Corresponding to these observations, the direction of best fissility of the granite coincides with the 16° direction. The latter is accordingly regarded as that of the 'open' cracks, and as the direction in which tectonic pressure was applied to the area during intrusion.

**An Irish Bog-flow**—Although bog-flows are comparatively rare events, a good many have been recorded in Ireland, particularly the famous Kerry flow of 1896. Few, however, are described in greater detail than the flow at Glencullin, Co. Mayo, in February 1931, of which Messrs. A. D. Delap, A. Farrington, R. L. Praeger, and L. B. Smith have recently published an account (*Sci. Proc. Roy. Dublin Soc.*, vol. 20, No. 17, 1932). This flow did much damage in destroying scanty arable land in the valley down which it swept for more than two miles. From a low ridge the flow suddenly started in peat about ten to twelve feet in thickness, until about 400,000 cubic yards had slipped down to the valley. At the first rush, the impetus was sufficient to cause the flow to rise on the opposite side some twenty-two feet above the valley floor. Immediately afterwards, the semi-liquid mass began to move down the valley. The harder, drier surface floated in the lower liquid bog as great floes or rafts. The flow was seen to advance like a wall down the valley. It carried stones and boulders with it. The writers of the report, in considering the cause of this flow, note a slight change in gradient where it began a little below a shallow tarn. The fracture was probably across the normal drainage of this tarn, and the lower layers of the bog were evidently in a saturated condition and without coherence. When the accumulation of water reached a certain amount, the 'burst' took place, and spread over the area of semi-liquid bog, ceasing where it reached drier under-peat.

**Variation of Hearing with Age**—There is a popular belief that hearing deteriorates with increasing age. In the *Bell Laboratories Record* for May, H. C. Montgomery describes a set of experiments made to determine the magnitude of this effect. The investigation was carried out with an audiometer on 200 employees in the laboratory, ranging in age from twenty to sixty.

years The audiometer produces any one of eight pure tones, varying in octave steps from a frequency of 64 to 8192 cycles These frequencies cover the useful hearing range and correspond to the *C*'s on the piano—omitting the lowest and adding one above the highest Measurements were made of the threshold of audibility at the various frequencies and diagrams were drawn These audiograms were divided according to age into four groups, each group ranging over ten years It was found that the difference between the thresholds of the youngest and oldest age group is quite small compared to the difference between the normal and those who have a difficulty in hearing In fact, at frequencies below 2000 cycles, the differences in the four groups are practically negligible At frequencies above 2000 cycles, the younger people hear the best In ordinary conversation, where speaker and listener are close together, this is not noticed In concert halls and theatres the effect is noticeable, some of the 50-60 group finding difficulty in distinguishing consonant sounds They thus mistake 'thin' for 'sin', 'famish' for 'vanish', etc The older group appreciate melody and rhythm as well as anyone, but the tones would sound more brilliant to youthful ears It is concluded that the average difference in hearing ability between twenty-five and fifty-five years of age is relatively small A further study including more advanced age groups might possibly discover marked differences in hearing ability

**Positive Ions of Mass 220**—L. L. Barnes and R. C. Gibbs announce, in a letter appearing in the *Physical Review* for April 15, that they have observed positive ions of mass 220 with a mass-spectrograph of the Dempster type The source of ions was a specimen of a mixed alkali sulphate, which was believed from X-ray analysis to contain a quantity of the missing alkali metal with atomic number 87 When heated in a high vacuum at a temperature of about 650° C, this gave rise to small but steady positive ion peaks in the mass-spectrum, a convincing example of which is reproduced The caesium ion currents from the same source at the same temperature were about ten thousand times greater, showing that the concentration of the heavier element is almost certainly only

minute The average value for  $m/e$  obtained from six curves was 220, with a maximum variation of not greater than one-half per cent, but a still more accurate determination of this quantity is being undertaken

**Spectra of Lead Isotopes**—The small differences in wave-length which were found more than ten years ago by Aronberg and Merton in the spectra of lead from different sources have been found by H. Kopfermann (*Z. Physik*, April 6) to come from differences in nuclear spin and hyperfine structure In the earlier work, this was not resolved, although the optical apparatus was of sufficient power, probably because of Doppler broadening of the lines on account of the high temperature of the source In Kopfermann's experiments, this is overcome by volatilising the metal in a gas discharge from a cathode kept cool by water or liquid air, and the hyperfine structure is readily observed The lines of uranium lead (206) and thorium lead (208) are all single and well separated, but the 207 isotope gives a more complex structure, the centre of gravity of which is intermediate between the terms of the lighter and heavier isotopes in the spark spectrum (Pb II) Kopfermann remarks that his results do not conflict with Schuler and Jones's discovery of a weak component of hyperfine structure, which they attribute to  $Pb^{204}$ , as they used much more intense sources

**Alchemical Manuscripts**—In the current number of *Archeion* (xiv, 1932, pp 57-61), Principal H. E. Stapleton publishes a preliminary account of the very important collection of Arabic alchemical manuscripts possessed by the Asafiyah Library of H. E. H. the Nizam of Hyderabad It appears that this collection comprises no fewer than 195 separate volumes, representing approximately 150 different treatises Twenty-two of the MSS are ascribed to Jābir ibn Hayyān, about a dozen to Aḍamir al-Jildakī, six to Muḥammad ibn Umayl (or Amyal), and three to Khālid ibn Yazīd, many other of the well-known Muslim alchemists also being represented Of considerable interest is the large number of works by previously unrecorded alchemical writers, which may be expected to yield valuable information when their study is undertaken Mr Stapleton promises a complete *catalogue raisonné* with as little delay as possible.

### Astronomical Topics

**Astronomical Notes for July**—Mercury is at its greatest elongation, 27° east of the sun, on July 20, but being south of the sun, it will only be seen with difficulty in the evening sky, it passes 2½° to the south of Jupiter on July 23 Jupiter is in conjunction with the sun on Aug 3, and is therefore too low for convenient observation in July Venus has become a morning star, but being still a thin crescent, it is not very conspicuous until the end of the month Saturn is in opposition on July 24, but its south declination of 20° makes delicate observations difficult There is only one occultation at a convenient hour, on July 10 the star  $\psi$  Virginis, of the fifth magnitude, disappears at 10 17 P.M. summer time, as seen from London No conspicuous comets are visible at the date of writing Ephemerides of periodic comets are given in the B. A. A. Handbook for 1932 Those who have suitable optical means should join in the search for Tempel's comet of the November meteors It will, however, be in a better position in a month or two

**Photography of the Full Moon**—Most photographers of the moon choose phases other than full for their exposures, in order to show the shadows, which aid in throwing the surface into relief Mr H. G. Tomkins, who has for many years made the moon his

special study, has lately taken a series of photographs of the full moon with the large reflector that he has erected at Dedham, Essex Ilford Astra plates were used with an orange filter, three prints from these plates are reproduced in *Monthly Notices* of the Royal Astronomical Society for April They were designed to bring out the contrast between the dark and the bright areas as strongly as possible, so that the maria are almost perfectly black and the brightest regions white But all through the bright regions there is a mottling of dark patches Mr Tomkins suggests that this dark eruptive rock forms a base extending over the whole surface of the moon, but overlaid in many places by some whiter material, pumice or volcanic ash are suggested, or possibly an efflorescence of some kind

The maria have some patches which are still darker than their general surface, it is shown that some of these are connected with the lava flows to which Mr. Tomkins directed attention in an earlier paper, they probably arise from an outpouring of dark lava on a surface that was already dusky

The paper also contains a study of the relative antiquity of various formations, thus the Mare Humorum is considered to have been the scene of comparatively late eruptions

## Vision

ON Friday, June 3, the Physical and Optical Societies held a joint discussion on vision at the Imperial College of Science, South Kensington. The meeting was divided into four sections, two in the afternoon and two after dinner. A discussion took place at the end of each group of papers forming a section.

The proceedings were opened by Mr J Guild, who in a general paper reviewed the scientific basis of vision. He pointed out that the retina is not the only factor concerned, for nerve tracts and endings in the central nervous system must also be considered. He stated that for colour vision there may be either three kinds of receptors with multiple central connexions, multiple sets of receptors with three groups of central connexions, or three sets of receptors with three groups of central connexions. The number three must come in because of the known facts of colour mixing.

Mr Guild also touched upon the problems of the nerve impulse and its relation to the intensity of a sensation, that is, if the nerve impulse is always of the same magnitude, is the intensity of sensation due to the frequency with which impulses follow each other up the individual nerve fibres? During the discussion it was stated that, from the physiological point of view, the intensity of a sensation depends upon the frequency of the nerve impulses, and that the more intense sensation, due to a larger area of stimulation, is related to the greater number of impulses in consequence of more nerve fibres being active.

Mr Guild also contributed a general paper dealing with the significance of measurements in visual work and with their mathematical treatment.

As might be expected, the word colour appeared in the titles of many of the papers and the subject of colour perception was discussed in many more papers, but other aspects of vision were also considered.

The more purely mechanical and optical aspects were dealt with in four papers. Prof A von Pflugk and Mr E F Fincham were concerned with the mechanism of accommodation. Mr Fincham believes that the lens is plastic and that its change in shape is due to the elasticity of the lens capsule. Presbyopia is due to increased rigidity of the plastic constituents of the lens. Prof von Pflugk contended that the zonule of Zinn is not responsible for the shape of the lens, but that the pressure of the vitreous with unslackened zonule produces the change in shape. The last word on this subject has not yet been said.

Prof C E Ferree and Dr G Rand presented a paper on the refractive conditions for the peripheral field of vision, in which the results of the examination of the eyes of twenty-one individuals were reported. Prof F Roessler described the method of testing for astigmatism by combined red and blue lights.

Visual acuity formed the subject of two papers. Dr R S Creed discussed the relationship of the retinal rods and cones, the nerve paths, and the frequency of impulses to visual acuity. Prof H Hartridge described the effects of chromatic aberration on the distribution of colour in the image of a point source of light.

The fundamental process whereby light stimulates the receptors in the retina was considered by Mr D Roaf. He showed, on the assumption that an increase in sensation denotes a definite quantity of decomposition of photochemical substance, that the acuity data of Houston agree with a bimolecular reaction for the synthesis of photosensitive material, but that the results will not fit the curve for a monomolecular reaction.

Prof A Bruckner presented a paper showing different rates of adaptation in a number of individuals

for whom the curves can be grouped into several classes. The condition of adaptation was mentioned by a number of speakers. Prof L C Martin wished to know whether the dark or light adapted condition were the simpler to work with. Prof H E Roaf agreed with Prof Martin that the dark adapted condition was simpler, but Dr R A Grant considered that the difficulty of accurate fixation makes the dark adapted condition more uncertain for experimental purposes. The condition of adaptation, that is, whether it is the result of diffuse illumination of neighbouring portions of the retina or whether it is due to the light shining on the same part of the retina as the test light, was not specifically discussed. From some points of view, Mr W D Wright's paper, "The Significance of Colour Fatigue Measurements", Dr R A Houston's on "New Observations on the Weber-Fechner Law", and Prof H E Roaf's communication were dealing with aspects of adaptation to light, as they described changes in sensitivity due to previous or simultaneous illumination of the eye. Messrs W S Stiles and B H Crawford measured the change in sensitivity due to extraneous light sources by finding out the illumination of the background or surrounding fields which produces the same alteration in visual threshold. They use this alteration in threshold as a measure of retinal adaptation.

The colour triangle received attention from two points of view. Prof J Drever presented results of estimations of the wave-length of 'pure' colours at varying intensity, showing that at 4710, 5080, and 5680 Å the colours appear pure even with marked differences in intensity. Prof Drever then pointed out the inadequacy of the colour triangle as a means of representing all colour sensations, including variations in brightness and saturation.

Mr T Smith dealt differently with the colour triangle. He folded it up, opened it out as a straight line extending to infinity, and brought it back as a much improved triangle in which variations in wave-length discrimination throughout the spectrum are of no significance.

The presence and number of different kinds of receptors (whether these depend on retinal conditions alone or beside the point) was considered from a number of aspects. Mr J Guild gave some sound generalisations as to what is implied and what is not implied by the Young-Helmholtz or trichromatic theory. His view does not entirely agree with that expressed by Prof W Peddie. Prof F Allen and Prof S Hecht each presented long papers. The former pointed out that his well-known observations by the flicker method can all be explained on the trichromatic theory. In the subsequent discussion, it was pointed out that the duration of the dark period cannot be assumed to depend only on the sensitivity of the eye, even when the intensity of the light is kept constant. Prof Hecht repeated his description of alterations in the sensation curves so that they form three almost identical curves. It did not seem reasonable to some of the participants that such closely similar curves could be a satisfactory basis for colour discrimination. Prof H E Roaf presented evidence in favour of there being three sets of receptors, one for the whole visible spectrum, one for red and green, and one for red alone. Absence or diminished specificity of the last would account for the ordinary defects in colour vision.

Various experimental papers were contributed, all of which will be useful in the final interpretation of the processes involved in colour vision. Prof L C Martin, Mr F L Warburton, and Mr W J Morgan

presented the results of observations on the number of recognisable steps between white and the spectral colours. There are fewer steps between green and white than between either red or blue and white. There are about an equal number of steps between either red or blue and white. This result agrees with the appearance that green has of being a less 'intense' colour than red or blue.

Prof H Hartridge described colour perception in an ivory white light formed by removing all the rays less than 5300 Å and some of the red. By such a light, it is possible to recognise pigmentary colours, but yellows are too pale, blues too dark, and purples too red. Ishihara's tests can be passed by a normal individual in such a light. These results indicate that the receptors for blue are probably stimulated by wave-lengths other than those less than 5300 Å.

Prof H Pieron's paper dealt with the time necessary for the production of colour by stimuli of short duration. For red the time is 95 σ, for green 105 σ, and for blue 120 σ, thus showing the slower response for receptors for blue.

There were five papers which dealt with the problems of interpretation of visual stimuli. Dr L F Richardson has obtained estimates of the relative amount of red in a given sample of colour, and finds that different individuals show an agreement between their estimates of the relative proportions of red and white in the mixture.

Prof F C Bartlett sent in a paper dealing with the visual perception of depth, and Mr H Bannister offered an explanation of Pulfrich's pendulum experiment. Prof Koffka described the phenomena concerned with contrast in the black-white series, and based a general theory of vision on the results.

Dr R A Granit enlarged upon the significance of the synapses in the retina in relation to the path of

the impulses proceeding through the retina to reach the optic nerve cells and fibres.

By the system of limiting each speaker to eight minutes, all the papers were disposed of in time to allow of discussion. As the authors did not reply to criticisms, we must await the publication of the whole discussion in order to know the final decision on some points. It might have been better if the papers had been grouped under subjects, though that is almost impossible, because so many of the subjects overlap, and until the papers have been read it is not easy to know under which subject to classify them.

Amongst the points brought out during the discussion are the following. It seems clear that vision is to be explained on a trichromatic basis. The actual wave-lengths that stimulate the different kinds of receptors are not yet determined. There is no certainty as to the relation between total brightness and the brightness due to the individual receptors. Even such a mechanical process as the change in shape of the lens during accommodation is not beyond the sphere of active controversy, so it is not to be expected that the more recondite processes of visual perceptions will be agreed upon with equanimity.

The discussion was undoubtedly successful and a worthy successor to the one held a year ago on audition. With all the papers but one in print, the authors had only to refer to the salient points.

Unfortunately, Sir John Parsons was unable to attend and to open the proceedings. Mr Guild undertook that duty at the eleventh hour, hence his opening remarks were not in print. From what one can recollect of them, the printed paper will be a valuable contribution to the philosophy of vision and a guide to future makers of hypotheses. All those interested in vision will look forward to the publication of the discussion in full.

### Research Defence and Anti-Vivisection

THE Research Defence Society was founded in 1908 by the late Stephen Paget. It was the outcome of the Association for the Advancement of Medicine by Research and Prof Starling's Committee which collected and presented evidence for medical and scientific research before the Royal Commission on Vivisection which sat in 1906-8. That Commission probed the anti-vivisection question to the depths, but declared in favour of research work under the Act of 1876, which has controlled the use of animals for experimental purposes in England for more than half a century. In spite of this rebuff, anti-vivisectionists have continued to attack research workers and their institutions, even those who are engaged on veterinary research. The Research Defence Society undertook to inform the public of the conditions under which animals are used, the need for the work, and the alleviation of human and animal suffering which has resulted from such work.

The Annual Report of the Society for the past year pays a glowing tribute to the work and devotion of the late Lord Knutsford, who had been chairman since 1908. The Hon Sir Arthur Stanley, chairman of the British Red Cross Society, succeeds Lord Knutsford as chairman of Committee, and Prof A V Hill has accepted the office of vice-chairman formerly held by Mr Stephen Paget, while the following have become vice-presidents of the Society: Mary Viscountess Knutsford, Mrs F M Sandwith, Lord Moynihan, Sir Frederick Gowland Hopkins, Sir Walter Fletcher, Sir Alfred Beit, Sir Henry H Dale.

During the year under review, an event of outstanding importance was the final judgment of the Court of Appeal and the Order of the House of Lords

in regard to the will of the late Mrs Sarah Martha Grove-Grady, who left her residuary estate, amounting to approximately £200,000, to found and endow a new anti-vivisection organisation. If this bequest had been held to be charitable, a slur would have been cast on medical and veterinary progress by research and on institutions registered under the Act of 1876, for the conditions she laid down even precluded the Royal Society for the Prevention of Cruelty to Animals from accepting any of her money, because it could not be said that all members of the governing body of that Society were confirmed anti-vivisectionists. Largely as a result of the endeavours of the Research Defence Society, the Court of Appeal reversed the decision of a lower court which had upheld the will, and an Order of the House of Lords finally settled the case by ruling that £25,000 out of the residuary estate should be devoted to the benefit of animals, provided that none of the money were used for anti-vivisection propaganda. The Research Defence Society urged that this money should be given to the Royal Veterinary College (which had been attacked by anti-vivisectionists), with the gratifying result that the whole of the sum has now been allocated to that institution for the purposes of building and endowing an animals' hospital.

The annual general meeting of the Society took place on June 3, in the lecture hall of the London School of Hygiene and Tropical Medicine. Lord Lamington, the president, took the chair, and Sir Arthur Keith delivered the sixth Stephen Paget Memorial Lecture on "Some Aspects of the Modern Conflict between Sentiment and Reason."

Sir Arthur opened by contrasting physical and

physiological research, pointing out that whereas the physicist has to satisfy only a scientific ideal, the physiologist has to confront an ethical as well as a scientific standard. "The conflict between sentiment and reason, as carried on to-day, finds its sharpest expression in the opposition offered to the beneficial work carried on by experimental physiologists. This society—the Research Defence Society—rightly concentrates its efforts on the vindication of the work carried on in our physiological laboratories. The anti-vivisection crusade is dangerous and has to be repelled, but after all, it is only an acute manifestation of a conflict which permeates modern society—a conflict in which blind sentiment is ranged against clear reason."

In dealing with the conflict between economic needs and sentiment, Sir Arthur pointed out the difference in the conditions when our ancestors hunted for their food and modern times when animals are deliberately bred for the butcher. We have to recognise by force of reason our economic needs, or, if sentiment becomes too strong, we must forswear all forms of animal meat. He continued, "It is not sentiment but reason which must be the final arbiter in the attitude we are to adopt to our four-footed dumb friends."

Discussing the problem of cruelty, Sir Arthur said, "The vice of cruelty has been given to man for the same reason as a sting has been given to the wasp and thorns to the rose—namely, for protection—to make their enemies afraid of them." In its primitive form it is a vice of hot blood, thoughtless cruelty, on the other hand, is a prevalent failing which everyone would wish to see eliminated. The most terrible form of cruelty is that which wilfully seeks to misinterpret motive. While there is need for a society to save animals from unnecessary suffering, there is still more need for a society, such as the Research Defence Society, to save scientific men from the cruelty of misrepresentation and of injustice.

Critics of research on animals have based arguments on so-called common sense, but as Sir Arthur pointed out, "When 'common sense' comes against expert knowledge, retreat is the wiser policy. Darwin's victory was one over the 'common sense' of his age. In the recondite fields of medicine, especially in the basal science of physiology, we must be prepared to be guided not by common sense but by the argument of irrefutable fact. We can hardly expect the man in the street, who has his own preoccupations, to know all that special experience has vouchsafed to us. If research is to prosper, the great public must be kept informed of its aims and accomplishments."

Sir Arthur then paid an eloquent tribute to the work for animals carried out by the Royal Veterinary College, and condemned emphatically the anti-vivisectionists who had attempted to frustrate the appeal of that institution for funds.

### University and Educational Intelligence

**BIRMINGHAM**—Applications from holders of an honours degree in engineering of a British university are invited for the James Watt Research Fellowship in Mechanical Engineering, the annual value of which is about £250. They should reach the Registrar of the University by, at latest, July 11.

**CAMBRIDGE**—The John Humphrey Plummer professorship of inorganic chemistry has been established, and the electors will meet on July 18. The stipend of the professor is £1200 a year or, if he holds a fellowship with dividend, £1000 a year. Candidates are requested to communicate with the Vice-Chancellor on or before July 7.

Applications for the Gwyneth Pretty Studentship, the holder of which shall devote himself to original research in the etiology, pathology, and treatment of disease, with particular but not exclusive reference to those diseases which cripple or disable in childhood or early life, are invited, and should be sent before July 30 to Prof H. R. Dean, Department of Pathology. The studentship is of the annual value of £200 and is tenable for three years.

The Lucasian professorship of mathematics will be vacated by Sir Joseph Larmor on Sept 30. A meeting of the electors will be held on July 25. The stipend of the professor is £1200 a year or, while the professor holds a fellowship of a college with dividend, £1000. Candidates for the professorship are requested to communicate with the Vice-Chancellor on or before July 11.

Dr W. H. Thorpe, of Jesus College, has been appointed University lecturer in entomology. Mr. B. H. C. Matthews, of King's College, has been appointed assistant director of physiological research.

APPLICATIONS are invited by the Royal College of Physicians of London for two Leverhulme research scholarships, each of the annual value of £500, for the investigation of some clinical problem of disease as it occurs in man. Applications must be sent before July 4 to the Registrar, Royal College of Physicians, Pall Mall East, S.W. 1.

THE Science Scholarships Committee of the Royal Commission for the Exhibition of 1851 has made the following appointments to Senior Studentships for 1932, the name of the recommending university being given in brackets: Dr S. Tolansky (Durham), for research in physics; Mr R. S. Alcock (Cambridge), for research in biochemistry; Mr S. H. Bastow (Cambridge), for research in physical chemistry; Mr. H. D. Ursell (Cambridge), for research in mathematics; Dr E. A. Moelwyn-Hughes (Oxford), for research in physical chemistry; Dr R. D. Preston (Leeds), for research in botany.

ELEMENTARY education in the United States of America is reviewed in *Bulletin* No. 20, 1931, of the Office of Education, Washington, consisting of advance pages of the official biennial survey for 1928-1930. Widespread appreciation of the conception of learning as an active rather than an absorptive process has led to notable improvements in equipment, courses, and instructional materials providing for constructing, illustrating, dramatising, modelling, and many other forms of creative activity. Elementary school aims have shown progressive enlargement of scope so as to include, in addition to the traditional function of instruction, the promotion of physical, recreational, educational, and social welfare outside the regular school day, as is evidenced by the creation of new posts such as home visitor, social care worker, after-school recreational director, and director of parent educational activities, and also by the linking up of school work with libraries, clubs, juvenile courts, Red Cross works, and community clinics. The instructional possibilities of radio and sound films have been receiving close attention. There has been a movement towards requiring a certain minimum standard of special qualifications when selecting school librarians, teachers of elementary school science, literature, and social studies. Finally, much ingenuity has been devoted to the elaboration of courses of study for pupils of different learning, interests, difficulties, or capacities.

## Calendar of Geographical Exploration

June 26, 1843.—The Wady Hadramaut

Adolph von Wrede started his journey inland from Makalla on the Gulf of Aden, and succeeded in crossing the barrier maintained by the sheikhs of the coast towns between long  $46^\circ$  and  $52^\circ$  for so long against foreigners. Disguised as a Mohammedan, he penetrated to the Wady Doan and ultimately reached the great sands of the Ahkâf, where he found that a sixty-fathom plumb line disappeared completely in the sands. He did not reach the main wady of the Hadramaut proper, but his journey established the general character of the fertile Hadramaut country as a system of branching valleys, deeply sunk in a high plateau and debouching into the great Wady Hadramaut Channel.

June 28, 1819 — Crossing Arabia from Sea to Sea

Capt G F Sadlier started on a mission which resulted in the first crossing of Arabia from sea to sea by a western European. He went to Hofuf in the Hasa Oasis, entered Nejd by the province of Yemama, passed south of Riyadh, and reached Anseiza. He arrived in the suburbs of Medina, but was not allowed to enter the Holy City itself, being banished to Bir Ali. There at last he had audience of Ibrahim, but Sadlier could come to no agreement with the Egyptian pasha. The British envoy and his party reached the Red Sea on Sept 20. Sadlier took many compass readings, recorded the names of all settlements which he passed or saw, and gave notes of the time occupied on each march. He also recorded many details relating to trade and transport, to the character of the settlements along his route, and to the type of cultivation of the soil. For the first time, medieval information about the peninsula was checked by actual survey.

June 29, 1871 — Route to the Polar Sea

C F Hall, in command of the United States North Polar Expedition, left Brooklyn in the *Polaris*. In 1860–61, I I Hayes had explored Ellesmere Island, between lat  $77^\circ$  and  $78^\circ$  N, and had reached Kennedy Channel, which he mistook for the open polar sea. Hall's voyage in the *Polaris*, when he reached  $82^\circ 26'$  N, was a result of the hopes raised by Hayes, and it finally showed the route to the polar sea, though Hall himself was taken ill and died while exploring Greenland. Hall made his first voyage in 1860, when, though his vessel was wrecked, he made a two and a half years' exploration by sledge and boat off Frobisher Bay, and Countess of Warwick Sound, returning with charts and with descriptions of native life. In 1864, Hall again set out to try to obtain news of Franklin's fate. After spending five years in the search, he returned convinced that there was no survivor of Franklin's party, and bringing back with him many relics of the Franklin expedition obtained from the natives.

July 1, 1648 — An Early Discovery of Bering Strait

A Cossack, Dezhnev, started from the Kolyma River on an exploring expedition, undertaken with the approval of the Russian Government, partly to discover islands in the polar sea which had been reported by hunters, and partly to increase the territory paying tribute to Russia. Dezhnev rounded the north-east point of Siberia apparently in open water, though he remarked that this sea was not free from ice in every year. He continued his voyage down the east coast of Kamchatka, and reached the mouth of the Anadyr River in October. The record of his voyage was long forgotten, but papers discovered concerning a quarrel

between him and a companion about the right of discovery to a walrus bank on the east coast of Kamchatka brought it to light. The Russians have renamed East Cape as Cape Dezhnev in his honour. These Cossack journeys in the polar seas are the more remarkable because the vessels they used were small rowing boats, only using sail in a fair wind, and were often caulked with moss mixed with clay and held together with willows. The strait between Siberia and America, through which Dezhnev had passed, did not become known until Bering's voyage in 1729.

July 1, 1906 — Grenfell on the Congo

George Grenfell died at Basoko. Grenfell began his geographical work in 1874, when he explored many of the navigable tributaries of the Congo. In 1884 he made a survey of the Congo up to the equator in long  $18^\circ$  E, and in 1885 ascended the Ubanga to the Zongo Falls. Later he explored the Aruwimi River, reaching Mawambi in November 1902. His work and that of von Wissman first elucidated the drainage of the Congo basin.

## Societies and Academies

### LONDON

Geological Society, April 27 — W F Whittard. The stratigraphy of the Valentian rocks of Shropshire: the Longmynd-Shelve and Breidden outcrops. A dual division of the Valentian rocks of Shropshire into a lower group, the Pentamerus beds, and an upper group, the Purple shales, was adopted. Further, two lithological subdivisions of the Pentamerus beds, the Arenaceous phase and the Mudstone phase, were recognised. The Longmynd-Shelve outcrop is divided into several areas by glacial deposits. The rocks of these areas exhibit different lithological and faunal characters, due to the variable conditions under which they were laid down. Two distinct faunas characterise the Valentian rocks of the main outcrop, and these were selected as the standard faunas. Several local modifications of each standard fauna are present in the Longmynd-Shelve and Breidden outcrops. The character of the sea-bed and the control it exerted on the kind of fauna which frequented a particular area were stressed, and attention was directed to the mud- and sand-loving genera and species. The encroachment of the sea over the district in Upper Valentian times resulted in a complicated region of land and sea to which the name of 'Salopia' was given.

### DUBLIN

Royal Irish Academy, April 25 — A W Conway. The radiation of angular momentum. The application of classical electrodynamics to the general problem of the radiation of angular momentum from an oscillating system of  $n^{\text{th}}$  order with  $4n+2$  amplitudes. Components of type  $\frac{sh}{2\pi}$  and  $\frac{1}{2}\sqrt{n(n+1)-s(s+1)}\frac{h}{2\pi}$  are obtained and an energy term of type  $\{n(n+1)-s^2\}\frac{h^2}{8\pi I} + Dn^2(n+1)^2$  — A W Conway and A J McConnell.

The determination of Hamilton's principal function. Hamilton's great contribution to dynamics was his discovery of his *principal function* by means of which he was able to bring dynamical theory under one central principle. He showed that the function satisfied two partial differential equations, but he failed to give any account of how it was to be formed other than by direct integration of the equations of motion. Jacobi's contribution consisted in showing that the paths of the dynamical system could be obtained from

a complete integral of the first of Hamilton's differential equations. The present paper completes the theoretical aspect of this question by describing a method of forming the principal function directly from a Jacobi complete integral.

## PARIS

Academy of Sciences, May 9.—J. Costantin. The importance of the mosaic disease of the sugar cane from the point of view of degenerescence. Sugar canes raised in the mountains in Java are resistant to the disease and this has been confirmed by experiments in the Dutch West Indies.—M. de Broglie and L. Leprince-Ringuet. The dispersion of the neutrons of beryllium and the existence of recoil nuclei caused by excited lithium.—Charles Nicolle and Charles Anderson. A new proof of the individual specificity of the spirochaetes of recurring Spanish-African fever. A reply to criticism by Delanoe. Further experiments are described proving that the results do not depend on the dose of the virus.—A. Yersin. Long survival of *Hevea* trees broken by a typhoon. Some of the plants, broken by the typhoon at heights of 1.2 metres from the soil in November 1926, are still alive. Although without leaves, they still produce latex in practically the same proportion as the uninjured plants. The rubber produced from this latex is normal.—Henri Buisson was elected *correspondant* for the Section of General Physics in succession to the late R. Blondlot.—Pierre Boos. The relation which exists between an arc of a curve and the angle under which it is seen from its origin.—Michel Fekete. Some generalisations of Jensen's inequality.—J. Leray. Certain classes of non-linear integral equations.—Vladimir Bernstein. The analogy between the distribution of the straight lines of Julia of holomorphic functions and that of the singular points of analytical functions.—P. Lejay and R. Goudey. Measurements of gravity made with the No. 2 Holweck-Lejay apparatus. The results of measurements made at 17 stations in France are given and a reduction formula worked out.—Albert Perard. A new line as a light wave standard of length. Instead of the green-yellow krypton line (5649), which is not very bright, the krypton line 5562 is suggested.—Jean Galibourg. The elastic limit of extra mild steel drawn out into wire. A study of the effect of keeping at the ordinary temperature.—Georges Vaudet. A vacuum contact breaker for high tension currents.—Raymond Dubois and Louis Laboureur. A direct reading electric chronograph allowing the exact measurement of very short time intervals.—Marcel Cau. The variation with the thickness of the magneto-optical effects by transmission through thin layers of iron.—Ny Tsi-Ze and Chien Ling-Chao. The photographic effect of pressure. If  $E$  is the illumination producing a density  $d$  when the emulsion is under a pressure  $p$ , and  $E'$  the illumination which produces the same density when the emulsion is submitted to no pressure, the ratio  $E/E'$  depends only on the pressure  $p$ . Above a certain pressure, 200 kgm/cm<sup>2</sup> for one plate used,  $E/E'$  is a linear function of  $p$ .—Jean Thibaud and F. Dupré la Tour. The penetrating power of the radiation (neutrons) excited in beryllium by the  $\alpha$ -rays. The neutrons from beryllium appear to be much more penetrating than would appear from the figures already published. Thus after passing through a screen of 30 cm of lead, one-tenth of the incident radiation remains. The absorption resembles that of a heterogeneous radiation, of which each constituent follows an exponential law.—Desmaroux. The mechanism of the decomposition of the nitro-celluloses. The experiments described lead to the conclusion that the principal phenomenon in the decomposition of the nitrocelluloses by heat, at least

in the first stage, is the destruction by a partial combustion of one of the residual glucose rings, followed by a break in the chain.—Mile Choucroun. Selective permeability and polarisation of membranes.—Felix Trombe. The preparation of metallic lanthanum free from iron and silica. The electrolyte was a mixture of lanthanum chloride, potassium chloride, and calcium fluoride. The cathode was molybdenum, and the deposited metal was collected in a crucible of fluorspar or silica. The metal was spectroscopically free from calcium and aluminium, and when collected in fluorspar contained less than 0.05 per cent silicon.—E. M. Bellet. The mechanism of the reaction of esters in the presence of alcohol in weakly alkaline medium.—L. Capatos. Some combinations of arsonium bases.—Ch. Courtot, M. Chaix, and L. Nicolas. The preparation of diphenylene sulphide. Study of Schonberg's method, the interaction of diphenylsulphonone and sodium amide, leading to a higher yield and to the isolation of some secondary products.—Mme Bruzau. The action of parabromanisylmagnesium on dimethylphenylacetamide.—Charles Dufraisse and Maurice Loury. Researches on the dissociable organic oxides. Three isomeric dimethylrubrenes,  $C_{44}H_{32}$ . Their dissociable oxides.—L. Domange. The action of heat on fluorspar. The luminescence produced by heating fluorspar crystals is not in any direct relation with a loss of material. It occurs when the crystals are broken.—Maurice Blumenthal. The structural elements of the Bokoya (Eastern Spanish Rif).—Marcel Thorat. A new contribution to the stratigraphy of the Cambrian and Silurian in the eastern part of the Monts de Lacenne.—G. Debebant. The kinematics of the isobaric centres.—Chadefaud. The physodes of the Pheophyceae.—Marc Simonet. The cytological study of the Pogoregelia hybrid, *Iris obiensis*  $\times$  *Iris Korolkowii*.—H. Colin and E. Bougy. The structure and richness in sugar of the hybrids of the beetroot.—Jan Hirschler. Certain membranous and granular plasmatic components in the male sexual cells of the Lepidoptera.—L. Lutz. The soluble ferments secreted by the Hymenomycetes fungi. The ketones, the anthraquinonic bodies, and the anti-oxygen function.—G. Stodel and A. Bourdin. The relation between the toxic power and the antigen power of the diphtheric toxins.—A. and R. Sartory, J. Weill, and J. Meyer. A case of blastomycosis of long standing transmissible to the guinea-pig due to a pathogenic *Saccharomyces* (*S. Jadini*).—Joseph Lignières. The determination of the types of aphthous virus.—Marcandier and Robert Pirot. The transmission from man to the guinea-pig (after passage through the rat) of the Toulon typhus virus (mild endemic typhus of warships).—E. Roubaud. The trophic strains of *Anopheles maculipennis* detected by comparative experimental cultivation.

## ROME

Royal National Academy of the Lincei, Jan. 3.—G. Fano. Birational transformations on algebraic varieties of three dimensions.—E. Paternò. (1) Action of sodium carbonate on cellulose. After immersion for three hours in water at the ordinary temperature, celluloses of various origins lose 0.5 per cent of their weight, this loss being doubled at 50°. The extents to which water and sodium carbonate solution are absorbed at 10°-12° may be taken as identical and as characteristic of the particular cellulose. For various sulphite wood-celluloses and for cellulose prepared by means of chlorine from straw, esparto, and hemp, such absorption varies from 98 to 152 per cent, the absorption seems to consist of simple imbibition due to the porosity. Cellulose containing relatively large proportions of  $\gamma$ -cellulose and pentosans (esparto

cellulose) is not suitable for the preparation of viscose, but preliminary treatment with sodium carbonate may be of use in such a case—(2) Exhausted cellulose. Cellulose which has been treated with sodium hydroxide solution—so-called exhausted cellulose—is a form of pure cellulose. Certain of the products known collectively as hemi-cellulose, whether pre-existent or not in wood, are formed also by the action of the air, the action being enhanced by the presence of water or salts, and to a greater extent by that of alkali—(3) Oxycellulose and its identity with  $\beta$ -cellulose and cellodextrin—L Cambi and G Devoto. The action of certain organic substances in the electrolytic deposition of zinc—Vladimiro Bernstein. The growth of holomorph functions of exponential type—G Lampariello. An equation of the partial derivatives of the fourth order—N Obrechko. A generalisation of Borel's summation of divergent series—P E Brunelli. Certain singular values of the critical velocities of shafts—A de Mira Fernandes. Zermelo's brachistochrone problem—Ioan I Placinteanu. The equations of the movement of three bodies of variable mass—G Viola. Certain peculiarities of the annual variation of relative humidity. In Italy, as throughout Europe generally, the relative humidity follows a law of variation opposed to that of the temperature, the minimum temperature corresponding with the maximum of humidity and vice versa. The results obtained at certain observatories do not, however, accord with this law, and are influenced, not only by the temperature, movement of the air, rainfall, etc., but also by the topographical position and by the frequency of wind. This is particularly the case at Gaeta and Chiavari, and the same would doubtless be found at other coastal stations—B Rossi. Calculation of the action of the terrestrial magnetic field on a corpuscular radiation generated in the atmosphere. The negative results of experiments made with the object of showing an action of the earth's magnetic field on the intensity distribution of penetrating radiation are usually regarded as a proof that the primary penetrating radiation is an ultra- $\gamma$  radiation, which generates in the atmosphere the corpuscular radiation revealed by the apparatus used. Consideration of this question leads to the conclusion that the corpuscular radiation observed cannot be the secondary radiation of a  $\gamma$ -radiation. Experiments on the subject are in progress—R Bruscaioni. The form of the interference fringes obtained from waves affected by pure astigmatism with gratings at any orientation—Paolo Straneo. The unitary theory of gravitation and electricity (4) Discussion and improvement of the earlier theory—G Piccardi and A Sberna. Molecular spectra and spectroscopic analysis (2) Investigation of lanthanum. From the qualitative point of view, the molecular spectrum method shows a sensitiveness equal to that of the spark spectrum method in the case of lanthanum. For low concentrations and in presence of elements of complicated spectra, it permits of more certain identification. For the concentration of lanthanum in solution, this method gives results of an accuracy corresponding with that shown by optical methods—L Mascarelli and D Gatti. Diphenyl and its derivatives (11) New derivatives of 2-methyldiphenyl and the influence of the methyl group on the reactions of an amino group in the 2'-position. The results of experiments on 2-methyl-2'-aminodiphenyl show that the hypothetical closure—by means of NH, O, or I—of a third nucleus at the 2-2' or 2-6' position never occurs, this indicating that the union between carbon atoms is stronger than that between other elements. Not only is the 2-methyl group not displaced, but it does not disturb any of the reactions of the 2'-amino group—G Natta.

and R Pirani. Solid solutions by precipitation and isomorphism between complexes of quadrivalent tellurium and platinum (1) Structure of caesium and rubidium chloroplatinates. These compounds form cubic crystals of the space-group  $Oh^8$ . The unit cell contains four molecules and has the side  $10.15 \pm 0.01$  Å for the caesium and  $9.83 \pm 0.01$  Å for the rubidium compound, the respective densities are 4.25 and 4.04. Calculation of the structure factor shows that the parameter  $u$  which defines the position of the chlorine ion has the value of about 0.23-0.24 for the caesium compound—C Sandonini. Transpositions in the benzene nucleus (1)

## Forthcoming Events

### SATURDAY, JUNE 25

BRITISH PSYCHOLOGICAL SOCIETY (General Meeting) (at National Institute of Industrial Psychology, Aldwych House, Aldwych, W C 2), at 3—Dr J W Cox. An Experimental Enquiry into the Effects of 'Practice', and of 'Training', in Manual Operations—B Babbington Smith. A Critical Examination of Recent Work on Perseveration.

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) (Annual Provincial Meeting) (at Alton)

JOURNÉES MÉDICALES DE BRUXELLES (at Brussels) (continued on June 26 to 28)

### TUESDAY, JUNE 28

NATIONAL PHYSICAL LABORATORY, TEDDINGTON, at 3—Meeting of the General Board of the Laboratory

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.30—Capt T A Joyce. The 'Eccentric Flints' of Central America (Presidential Address)

### FRIDAY, JULY 1

GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College), at 7.30—Dr T Neville George. The Superficial Deposits of the South Coast of Gower—Dr A W Groves. The Geology of Uganda, B E A, with special reference to the Tectonics (Lecture)

## Official Publications Received

### BRITISH

The Imperial Council of Agricultural Research. Scientific Monograph No 1. The Fungus of India. By Dr E J Butler and Prof G R Bisby. Pp viii+237. (Calcutta: Government of India Central Publication Branch.) 5 12 rupees, 11s.  
Journal of the Royal Statistical Society. New Series, Vol 95, Part 2. Pp viii+185 394. (London: Royal Statistical Society.) 7s 6d.  
Transactions of the Institute of Marine Engineers, Incorporated. Session 1932. Vol 44, No 4, May. Pp 167 218+xxvi. (London.)  
Transactions of the Royal Society of Edinburgh. Vol 57, Part 1, No 8. The Development of the Sorus in some Species of Nephrolepis, together with some Observations on points of Anatomical Interest. By Dr Isobel M Case. Pp 259 276. (Edinburgh: Robert Grant and Son, London: Williams and Norgate, Ltd.) 2s 3d.

### FOREIGN

Smithsonian Institution. Bureau of American Ethnology. Bulletin 105. Notes on the Fox Wapanawiwani. By Truman Michelson. Pp v+195. 35 cents. Bulletin 107. Karuk Indian Myths. By John P Harrington. Pp v+34. 5 cents. (Washington, D C: Government Printing Office.)  
University of California Publications in American Archaeology and Ethnology. Vol 31, No 2. The Northfork Mono. By E W Gifford. Pp iv+15 65+16 plates. (Berkeley, Calif: University of California Press.) 1 25 dollars.  
The Academy of Natural Sciences of Philadelphia. 1931 Year Book. Pp 62. (Philadelphia.)

### CATALOGUES

Liver Extract B D H. Pp 11. (London: The British Drug Houses, Ltd.)  
Società di Esportazione Polenghi Lombardo Industria del Latte. Pp 256. (Lodi.)  
Catalogue of New Books of all Publishers on Physics and Mathematics. Pp 26. (London: H K Lewis and Co, Ltd.)  
Ornithology (New Series, No 28). Pp 56. (London: Wheldon and Wesley, Ltd.)  
Sotheran's Bibliotheca Chemico Mathematica. Catalogue of Works in many Tongues on Exact and Applied Science. First Supplement. Pp xii+490. (London: Henry Sotheran, Ltd.) 10s 6d net.
